Molded shapes ranging from ordinary water-table brick to life-size statuary
... color combinations of your own selection ... an unusual variety of textures ... these are a few of the services Metropolitan renders regularly to architects. No brick work requirements are too difficult for these modern plants. For suggestions and new ideas, write for the first of a series of brochures entitled "Studies in Brick Work."

The Metropolitan Paving Brick Co., Canton, Ohio ... 41 E. 42nd St., New York City.

HANLEY
Golden Grey
BRICK

were designed for this building to blend with the seam-faced stone used for the lower two stories.

The spandrels are warm rose colored brick which blend with the wall as a whole and add a note of color warmth to this 1932 forty-eight story addition to the financial district skyline.
The panels on the cabinet in this display room and on parts of the kitchen walls are Formica. Formica is also very widely used for kitchen cabinet tops.

It brings a new note of color and beauty into the kitchen and retains its smooth surface and perfect color during long service.

Where a dishwasher is to be installed this top is of especial value because it is flexible and non-metallic, it dampens the noise of operation.

Builders and real estate men find that Formica in the kitchen makes houses easier to sell or rent.

THE FORMICA INSULATION COMPANY
4620 Spring Grove Avenue, Cincinnati, Ohio
**Fins BELONG ON FISH**

*DOUGLAS FIR PLYWOOD FORM LUMBER GIVES YOU CONCRETE SURFACES SMOOTH AS LIMESTONE!*

GOODBYE, old-style concrete walls — with ugly fins that are costly to rub off! A new era of concrete construction is here — and alert contractors and architects are already making the most of it with the new, specially fabricated and treated Douglas Fir Plywood.

Ordinary commercial Douglas Fir Plywood can be used once or twice with very good results, but the new Douglas Fir Plywood form lumber gives you repeated use — as many as seven to ten times — plus the usual plywood advantages of light weight and speed in carpentry.

Douglas Fir Plywood comes in large-size panels up to 4 by 8 feet, saving fully 10% labor over shiplap construction. There are fewer joints in a plywood form — and these stay tight, retaining all the moisture in the concrete.

Mail the coupon below for helpful facts and a free sample.

---

**DOUGLAS FIR PLYWOOD**

**COMPLETED SECTION OF VIADUCT:** Note the limestone smoothness of the concrete when Douglas Fir Plywood is used for form lumber. The surfaces need no plastering or rubbing. If painted, they need less paint, require less labor.

**DOUGLAS FIR PLYWOOD MFRS., Dept. 732-J, Sixth Floor, Skinner Bldg., Seattle, Washington.**

**Gentlemen:** Please send me a free sample of the new special Douglas Fir Plywood for concrete forms, and your Bulletin on "How to Make Concrete Flawlessly Smooth at Low Cost."

Lewis & Bros. Co., Wistar Building.
The Principal didn't look very dignified . . but he had a reason

He was watching a golf ball . . watching it measure the comparative resiliency of two floors widely used in schools. Simple as this test may be, it is none the less convincing. On hard floors (wood or concrete) the ball bounces high. On a resilient floor of Sealex Linoleum, the ball bounces low. The diagram above shows the approximate difference.

This matter of resiliency is important. The low bounce on Sealex Linoleum means that a good part of the shock of impact has been absorbed by the floor. Hard-working teachers—many of whom are in the habit of standing up while they conduct classes—will be less fatigued at the end of a day spent on Sealex Linoleum Floors. Also—more resiliency means less noise. Sealex Floors help students concentrate on their studies.

Write our School Floors Department for further information. Ask particularly about the new Veltone effects in Sealex Floors. Veltones combine cheerful color with good taste—durability with economy. Get the facts about our Bonded Floors expert installation service—in which Sealex materials are backed by Guaranty Bonds.

CONGOLEUM-NAIRN INC., KEARNY, N. J.

SEALEX LINOLEUM FLOORS
Exactly what you desire in color and design—that is one of the satisfactory dividends obtained from an investment in an Atlas White terrazzo floor.

With this modern flooring material, you may create your own patterns and color schemes. Terrazzo designs are limited only by convention and the imagination. To carry out the designs created, you may select from a wide variety of marble chips of many colors and shades; you may select from a number of color pigments for matrix tints; you may create innumerable effects by variation and combination. Whatever the design, whatever the colors, they will be faithfully interpreted with Atlas White portland cement.

Further information on terrazzo made with Atlas White portland cement will be furnished by terrazzo contractors or by Universal Atlas Cement Co.

208 South La Salle Street, Chicago
Subsidiary of United States Steel Corporation

ATLAS WHITE PORTLAND CEMENT
PLAIN AND WATERPROOFED
IT MAY be that the unsettled conditions which prevail generally throughout the world have contributed largely to the conviction, current in many quarters, that the status of the architect is now undergoing a radical change. In speaking about the place of the architect in a future period of building industrialization, Harvey Wiley Corbett has gone so far as to state that if the architect did not change as the times changed he would be in the same position as the carriage builder at the advent of the automobile. It is a subject not to be dismissed too lightly, and for the August issue we have asked several prominent men—some of them architects, some of them economists, some educators and engineers—to give briefly their views on the subject. We are confident that it is provocative of a wider professional comment and look forward to receiving a letter from you stating your reactions, and your own ideas.

THE current issue contains a survey of New York’s Lower East Side by Harland Bartholomew in which the problem of this huge area is stated in the clear terms of economics, traffic, population and use. In the August issue, John Taylor Boyd, Jr. presents a solution to this problem insofar as it can be solved by a planned housing development. There are, of course, innumerable complications inherent in any plan for urban rehabilitation. Mr. Boyd’s scheme is important in that it cuts across the limitations of individual restrictions and presents a comprehensive community development directly related to the master plan developed from extensive research.

A COMPANION article to that of Mr. Boyd’s is the summary of studies for similar “superblock” communities developed by the architectural group of the New School for Social Research in New York. They indicate several well-considered solutions to some of the generally fundamental problems existing in any problem of this kind. The PLATE SECTIONS of the August issue will contain a particularly diversified series of illustrations. Among them is the Department of Commerce Building at Washington, the Science Building for A Century of Progress Exposition in Chicago, the notable New Haven Lawn Club, a new publishing plant in London, England, the new biology building for Harvard University at Cambridge, Mass., and, in THE FORUM OF SMALLER BUILDINGS, a number of plates illustrating beach clubs and swimming pools.
It is particularly appropriate that buildings of such character as the Lawson Memorial Y. M. C. A. be glazed with Libbey-Owens-Ford Double-Strength "A" Quality Window Glass, for the exceptionally high quality and remarkable clarity of this fine glass are memorials in themselves to the character of the man whom the building commemorates.

Libbey-Owens-Ford Glass Company, Toledo, Ohio, Manufacturers of Highest Quality Flat Drawn Window Glass, Polished Plate Glass and Safety Glass; also distributors of Figured and Wire Glass manufactured by the Blue Ridge Glass Corporation of Kingsport, Tennessee.

Libbey-Owens-Ford Quality Glass is labeled for the protection of architect, builder and owner.

This House Was Still Spotless White Five Years After It Was Painted

It is at Portland, Oregon, and belongs to Harry A. Herzog, who designed it, lives in it, and painted it five years ago with Cabot's DOUBLE-WHITE. He writes as follows:

"Five years ago, I built a little home for myself. The exterior is hand split cedar shakes and the chimney common brick. I used two coats of Cabot's DOUBLE-WHITE for the finish. Curiosity as to the lasting qualities of this material kept me from repainting as soon as I normally would.

"I recently made a careful investigation and I was unable to detect one spot on the shakes or bricks where the original material had not been in the slightest lost — I intend to give it but one additional coat and see how long that is going to last. The clean whiteness of the exterior is always a pleasure to me and a source of wondering comment to all who see it."

Made on a new colloidal principle, fewer coats of Cabot's Collopakes go further. Because of this and because of the essential qualities of long-life, lasting smoothness and resilience, BLOXONEND is laid directly over concrete or wood subfloors. No pitch, glue or other adhesives used. Write for Architectural Specifications.

CABOT'S DOUBLE-WHITE COLLOPAKES
Made by the makers of Cabot's Creosote Shingle and Wood Stains

Please send me Color Card and full description of Cabot's DOUBLE-WHITE and Collopakes.

The modern restaurant is bright, fresh, colorful. For practical reasons this atmosphere must be easy to maintain; that is, the interior finish must be easily cleaned and its freshness lasting. Micarta fully meets these requirements.

Micarta offers new possibilities for the architect and builder in wall paneling, baseboards, and finishes for fountains and other fixtures. It is hard and scratch-resistant but not brittle. Hot coffee and strong cleaning compounds will not harm the smooth Micarta surface—even alcohol cannot damage its finish. A cigarette carelessly left to smolder on a table topped with Micarta leaves no mark.

May we send you our new booklet explaining the possibilities of Micarta for both interiors and exteriors? It will show the many patterns and colors awaiting your selection. Simply mail the coupon.
HOME builders today are offered a host of new conveniences—unique among which is fuseless wiring protection made possible by the Westinghouse NOFUZE Load Center.

This revolutionary new device replaces the old-style fuse box under the cellar steps and banishes forever the annoyance and inconvenience incident to blown fuses. When a dangerous overload occurs, the Flip-on or small automatic circuit breaker guarding that circuit opens, thus protecting the wiring. When the overload has passed, the flip of a handle restores service instantly. There is nothing to burn out—nothing to replace.

Architects find the Westinghouse NOFUZE Load Center attractive in appearance, easy to install and moderate in cost. Its protection is assured because its action cannot be blocked or its calibration changed by unauthorized persons. It may be placed in the kitchen or other central spot; it is as easy to operate as the familiar wall switch, and as safe.

The NoFuze Load Center is listed by the Underwriters’ Laboratories, and is the type of device specified for a recent “House of the Month”.

We will gladly send a bulletin on Fuseless Homes to any Architect interested.
ALLEGORY OF WEALTH AND BEAUTY

PAINTING BY HILDETH MEIERE ON THE CEILING OF NO. 1 WALL STREET, VOORHEES, GMELIN AND WALKER, ARCHITECTS
WHAT is ornament? What is decoration? Do we want either, or shall we discard them? Can we? These are debatable questions, yet man's impulse toward the decoration of all that touches his life, all that he wears, uses and lives in, is so universal that it seems that it can be accepted as a fundamental part of human nature. The simplest and most prosaic of primeval garments soon became embroidered or trimmed with a bit of fur; the handle of the primitive spoon or tool was carved to make it attractive or individual, and throughout the history of architecture we find man's habitations developing from crude shelters into aesthetically satisfying creations, enriched with ornament.

This is true of all races of whom we have record, and it is true of all parts of the world. The African savage's idea of what constitutes beauty or decoration may not be ours. He tattoos his body and paints designs on his shield; we enamel our finger-nails bright red, and go in for chromium figures on radiator caps — but it all has its roots in the in-suppressible human instinct to decorate. Decoration is not a negation of efficiency or suitability of form to purpose; it is its enhancement.

Most people select their clothes according to their ideas of what is pleasing in color, texture and design, quite apart from their practicability, and even when their ideas are molded for them by Fashion, they are selecting not only a protective covering but an adornment. The manufacturers of the things we use are in constant competition to make their wares more attractive to us by some appeal to our aesthetic sense, whether it be the design of the upholstery in the automobile or the color of the fountain pen; and upon the architects who design our buildings rests the responsibility of giving us what we demand — something beautiful as well as efficient in housing our activities.

I have perhaps identified the beautiful with the decorated in what I have said, and I should therefore explain my meaning of the word. To my mind, decoration is that which gives color or texture, scale or pattern or interest, which is used, whether functionally or not, because it gives pleasure or expression. An architect instinctively employs it because he is an artist who designs for aesthetic enjoyment as well as a builder who must build adequately for physical needs. . . . To choose a certain brick for a wall, is to choose decoration; to design a terrazzo floor, is to start ornamenting.

The extreme Left Wing Modernists have confused decoration with historic ornament, and I feel that in disclaiming all interest in decoration or ornament they are taking an attitude that they will eventually abandon. Human nature demands interest and relief from barrenness by some sort of enrichment. Even the most modern architects must deal somehow with their plain surfaces and that, under my definition, brings them to decoration in spite of themselves. Cornices and columns may be relegated to oblivion but windows and doors remain. How can one treat these elements without evolving some expressive form and treatment of texture and color? Granted that something new must evolve to be appropriate and right with the new conditions and tastes in architecture itself, granted that perhaps even the conception of decoration is developing from that of a generation ago, we cannot get away from its necessity — nor should we try.

One of the great reasons for the unquestionable
increase of interest in the broader conception of the decorative problem, is the variety of new materials which are coming on the market every day. The use of color has increased amazingly, and is being given consideration as never before. New metals, new structural materials, new fabrics, compounds, alloys and aggregates are being introduced, while the old materials, such as glass, wood, ceramics, marble and established metals, are being presented with new finishes, new properties, and new advantages.

This rising tide of products is being directed to the architect’s attention, and it is his tremendous task, along with all his others, to select from them what he needs for his building and to direct their application. His primary and ultimate responsibility for the effect of the finished building is a heavy one, and is inherent in his position as creator and coordinator. He cannot escape it on any plea, and on his judgment, taste and often courage and inventiveness in the selection or use of decorative materials may rest a large part of that effect.

During the past ten years it has been my privilege to work for a number of distinguished architects who have done pioneer work with new mediums and materials, but who have done even more — pioneer thinking in the decorative field. As a mural painter and decorator I presume to speak to them only in relation to what I know personally. Their decorative conceptions are, of course, only a part of their contribution to architecture, as such. Among them I would like to list the late Bertram Grosvenor Goodhue and the Goodhue Associates; Voorhees, Gmelin and Walker, Ely Jacques Kahn and three firms now associated in the designing of Rockefeller Center.

Of Mr. Goodhue it has been said that he is the only man to be claimed by both sides of the great Traditional vs. Modern argument. His attitude towards new materials was certainly that of a
modern, and he was the ideal type to carry us forward—interested, enthusiastic, perfectly sure of what he wanted, with courage to buck his judgment, and a willingness to experiment. True, though he was interested in a thing because it was new, he always considered it in its final effect, and he had a singular capacity for feeling that effect from the beginning.

The well-known Acoustalith was developed by Professor Sabine of Harvard with the cooperation of Mr. Goodhue, who used it extensively in his buildings. In designing the dome of the Academy of Sciences at Washington he wished to use this acoustic material, as the rotunda was to be the main speaking hall. Such a huge expanse of the plain brick he felt would be unhappy, and he set about finding a method of decorating it. Some experiments with paint on the brick were made, and I remember seeing him make faces at the unpleasant result. It looked poor and thin on the rough surface, and he was particularly sensitive to texture. By doing the design in flat relief in gesso, which was then gilded or painted, we finally got a rich and colorful effect, and by using a sort of grill work all-over design, the sound absorber was left sufficiently exposed to fulfill its function. This to my mind is a perfect example of an aesthetic demand being made of a new material and of a beautiful as well as an appropriate and practical result being obtained.

In speaking of the Nebraska State Capitol, it is hard not to speak of the daring and originality of the design as such, and the same is true of all the interior he lived to design in detail. He was extremely fond of ceramics and felt that something could be done with it in a very large scale. The dome of the vestibule was designed along the suggested lines, and he approved the cartoons. It was an experiment. Nothing quite like it had been attempted before, and the result was just what he had foreseen, brilliant and interesting in texture and color, handsome
Decorative frieze for the House Chamber of the Nebraska State Capitol. The historic figures are silhouetted in gold leaf on the walnut frieze which forms the lower part of the ceiling, making a band nearly 230 ft. long in scale and in complete sympathy with the other materials surrounding it.

Afterwards I designed three other ceilings or domes for the same building, in the same material. Technically I had nothing to guide me but the limitations of the material. Each piece had to come within certain over-all dimensions, and certain shapes were to be avoided because of the danger of breaking in the kiln. I found it was best to select colors from the stock samples, as getting a required color in ceramics is sometimes impossible and always necessitates long experiments and added expense.

This and the panel on the opposite page are ceiling panels for the Nebraska Capitol
A continuation of the decorative frieze in the House Chamber of the Nebraska Capitol, a fortunate treatment since it preserved the acoustic properties of the ceiling, and added sufficient color to the dignified setting.

The design was as structural as I could make it to avoid under glaze painting — using the joint line, like the leading in stained glass, and as few colors as possible.

It was after Mr. Goodhue’s death that the decorative floor at the Capitol was decided upon and designed, but I feel sure that he would have given it every encouragement. The first idea was to make it as the floor in the Sienna Cathedral, in large slabs of marble with a tight joint. This was found to be prohibitive in cost, so experiments were made in terrazzo. This was felt, however, to be too small in...
The ceiling of the lobby at No. 1 Wall Street in New York, worked out in silver leaf with color air-brushed over it. Cartoon for the ceiling of the main foyer and corridor of the Walker-Lispenard Telephone Building, executed in silhouette mosaic, a combination of glass mosaic and colored plaster, a technique particularly adapted to modern design scale for such great expanses. The Di Paoli Company finally evolved a combination of marble mosaic for the figure panels and cosmati for the borders, which gives the required vigor.

The decoration of the House Chamber for the Nebraska Capitol presented an interesting problem. It is a combination of walnut and Sanacoustic, the latter painted the same color as the wood. There is a great frieze of the walnut forming the lower part of the ceiling and on this I have put a procession of silhouette figures in gold leaf, ornamental in effect and forming a band nearly 250 ft. in length. It is of historic as well as of aesthetic interest. The room is a better place in which to deliberate because of the influence of such decoration. No ornament on the large acoustic surfaces was attempted.

For acoustic reasons it became necessary to hang tapestries in the Senate Chamber. The character of the room being already set by the Indian ceiling, an Indian character was called for in the tapestry designs. By using a very coarse, eight-point weave and adapting an Indian design, the required effect has been achieved. I mention it because, while I had never designed a tapestry before, and the weavers,
The tapestry designed for the Senate Chamber of the Nebraska State Capitol to meet an acoustic problem. The necessarily strong effect was obtained by using a very coarse weave and adapting an historic Indian design.

Renou, Coulaz, Riesen & Co., had never done anything of the character before, we had no trouble whatever after we had clearly established in our minds what effect was to be produced.

The ceiling of the lobby at Number One Wall Street, which Kimon Nicolaides and I designed with Voorhees, Gmelin and Walker, the architects, was extremely interesting—a fresh concept to meet modern decorative needs. The walls were of black marble and the ceiling was the reflecting surface for the light. The design, therefore, could not be heavy either in mass or in color, or the effect would be too dark. Many experiments with silverleaf were made, and the incidental veils of color were blown on with an air brush.

Glass mosaic can hardly be called a new material, so I will only mention that the cartoon for the red room in the same building was somewhat difficult because of the extremely complicated developments of the surfaces.

The Walker-Lispenard Telephone Exchange, also designed by Voorhees, Gmelin and Walker, has in its outer entrance a large map of the world, in building tile, the same material used for the walls.
throughout the main corridors. There was an alternative between this material and a painted canvas, and we all felt that the brick was much happier in the place, and finer in texture and scale.

There, again, is an example of an architect having the courage to try something new for the sake of a desired expression of purpose in a simple, decorative idea.

The main foyer and corridor ceiling in the same building is to be in silhouette mosaic, a combination of glass mosaic and colored plaster. This technique, which is so adaptable to modern needs in decorative design, has been delightfully handled by the Ravenna Mosaics. It is always a pleasant shock to me to find how far superior the finished craft work is, to the cartoons. This is true in every medium for which I have designed, and makes me realize how much lies in the beauty of the material itself, the value of its texture, the character of its surface and color.

Modern decoration will take these things into account in its design. As long as there are thoughts and feelings or aspirations to be expressed in our buildings, so long must our decoration find forms and techniques to embody them in harmony with the structure. The nature of the material affects the form, for the same idea expressed in metal will differ from that in stone, or mosaic, or fresco, and yet be the same idea.

I have spoken of ceramics, mosaics, new acoustic materials, fabrics, terrazzo, paint and gilt, marble and silverleaf and even brick tile. At present I am working on decorations in metals with enamel, in combinations and at scales never previously attempted, and at the same time painting on canvas a new series of maps. The range is greater than this and is ever expanding — a challenge to our ability. Architects, artists and artisans will work together to make the buildings of our time expressive of ideas, ideals and interests beyond the technical solution to the problem of enclosing space efficiently.

The third of the three plaques to be executed for the exterior walls of the Rockefeller Center theater. This one represents the drama. Enamel and metal never having been used before in such scale, the result is certain to be most interesting. The panels will be executed by Oscar Bach.

CHURCH OF OUR LADY OF LOURDES
LOS ANGELES, CALIFORNIA
L. G. SCHERER, ARCHITECT
THE building, erected for the Roman Catholic Church, is of reinforced concrete construction and of earthquakeproof design. Filler walls are of brick, and the floor joints of structural steel. The exterior is finished in coral-gray, integrally colored, textured plaster, trimmed with cast stone of similar tone. The tower, 110 ft. high, is capped in gold mosaic. With a seating capacity of 750, the church cost $58,970, or 14.5 cents per cu. ft. for 392,182 cu. ft.

LOS ANGELES, CALIFORNIA

L. G. SCHERER, ARCHITECT
The arches the interior is a buff colored acoustic plaster, the beamed ceiling being covered with sandblasted insulite. The columns and soffits are finished in colored concrete. With the exception of the sanctuary floor, which is of coral-colored terrazzo, the floor is of concrete. The Baldichino is of scagliola to imitate Campan Melange marble. Stations of the Cross were taken from the old church and built into the walls. Lighting fixtures, decoration, and art glass were still incomplete at the time the building was photographed. Above is a view looking toward the sanctuary, and at the left is a detail of the confessional.

ROCKEFELLER CENTER, NEW YORK, N. Y.
REINHARD & HOFMEISTER, CORBETT, HARRISON & MACMURRAY,
HOOD & FOUILHOUX, ARCHITECTS
In the evolution of the design and plan for Rockefeller Center, important decisions made after the preliminary drawings had been released have altered the character of the project to a considerable degree. Photographs were shown in the January issue of The Architectural Forum of the development as it was then planned. The drawings presented now illustrate the final scheme, as the group will look when completed. Probably the most significant changes have taken place on the Fifth Avenue frontage, where in place of the original oval bank building two small foreign buildings will be constructed, and where in place of a proposed department store on the northeast corner of the development, units are to be built for Italian and one other foreign interest. The bridges over the streets, joining the central office building with two theater units, are comparatively new developments, and the character of the Forum, shown above as it will actually appear, has undergone a great many changes. It is now a sunken plaza with entrances leading from it to the shopping level below ground. Since landscaped roofs were first proposed plans for their use have been revised several times. The drawing opposite of the International Music Hall roof is typical of the proposed treatment. A restaurant, an open-air concert hall, and possibly an open-air sculpture museum will be located in the roof gardens. The International Music Hall, which, with the exception of the sound motion picture theater, is nearest completion, is shown for the first time on page 20. This is a view along 51st Street toward Sixth Avenue, showing the private street in the foreground, which is to cut across the development from 48th to 51st Street.

ABSENCE of decorative pattern and emphasis upon color and form mark the treatment of this apartment house lobby. The walls are predominantly yellow, with gray and blue used in mass for relief. The ceiling is white and the floor terrazzo. The furniture is chrome-plated with white leather upholstery. Light is supplied by chrome-plated fixtures and a ground glass wall panel.

LOBBY OF CAROL COURT APARTMENT
SUNNYSIDE, LONG ISLAND, N. Y.
CLAUS & DAUB, ARCHITECTS
THIS is the living-dining room of a small apartment, redesigned by the architects for the use of one of the members of the firm. Although the structural character of the building prevented complete conformity with the principles of design subscribed to by Claus & Daub, simplicity governed by use was adhered to as far as possible. The wall surfaces are smooth off-white plaster, the ceiling white. The carpet is a dark shade of tan, and the drapes are blue and gray. All furniture, including the glass-topped table, is chrome-plated, the settee having a white leather cover and the chair a deep red cover. The light over the table has a green enamel shade, and the one at the left is chrome-plated. The door at the left is black.

APARTMENT OF GEORGE DAUB
NEW YORK, N. Y.
CLAUS & DAUB, ARCHITECTS
FROM A PHOTOGRAPH OF THE MODEL

STUDIO APARTMENT BUILDING
PHILADELPHIA, PA.
NORMAN N. RICE, ARCHITECT
THE project shows an interesting solution to the building problem imposed by an 18 x 100 ft. corner lot. The code restricted the coverage to 90 per cent and specified in addition the separate fire tower with an exterior entrance to the public hall on each floor. The fact that the long side of the building faced the north determined the use of the building for studio apartments and the restricted space, further hampered by the necessity of an interior corridor, brought about the expedient of providing a bedroom and bath on the mezzanine floor. The building is designed for a reinforced concrete frame. The spandrels at the floor levels are faced with a light buff enamel brick, the spandrels at the mezzanine floor being of unpolished metal.

STUDIO APARTMENT BUILDING
PHILADELPHIA, PA.
NORMAN N. RICE, ARCHITECT
THERE will be no housing — worthy of the name — until many of the shortcomings of our present system are eliminated. The laissez faire concept has brought about monetary rewards (and losses) for speculative competition in building, disregarding entirely the public good. Uncontrolled building irrespective of needs has produced a surplus of some types of building and a dearth of decent dwellings for most of the population. With seemingly no chance for individual profit by a speculator except through ill-planned, firetrap, shoddy rows, building has only been undertaken in fields that promised profit regardless of the welfare of the community. Now that the folly of such procedure is demonstrated there is a return to the sanity of studying needs and a willingness to consider a new order — logical, social, economic — planned for the good of all. Food, clothing and shelter are the essential needs — and housing is the need which the building industry must fill.

One of the primary objectives of the industry and of the architect (the planner and coordinator of that industry) under whatever social order, must necessarily be the production of housing — decent housing for the whole population — produced at low cost in large-scale projects creating planned communities.

Let us sum up therefore those things which we now have that encourage the immediate undertaking of housing, and those things which we lack, that we may work to eliminate our shortcomings.

We have:

A Demand and Market — for the housing it is our object to provide. The need and its statistics do not need reiteration here.

Labor — waiting for the chance to go to work to produce the buildings. Trained, technical and skilled labor is ready to begin.

Materials — on hand or manufacturers eager and able to produce them at low cost.

Locations — either now occupied by unfit or vacant buildings or slums, blighted areas, or unoccupied tracts already supplied with streets and sewers, etc.

Time — for the study and development of housing. We’re not too busy now to think or to act to make up those things we now lack.

We lack:

Funds — capital, credit, to finance large-scale housing. This may be made available shortly through Federal aid as the various bills now before Congress are passed.

Financing Methods — which will insure safety and stability and lessen the cost of housing to the ultimate consumer. Practical methods have been advanced recently and deserve thorough trial.

Tax Systems — which will be more nearly equitable and which encourage good rather than shoddy construction.

Laws — in every State, enabling and encouraging the formation of housing corporations to undertake the work of housing under adequate technical, social, economic and architectural control to insure the value of the projects. Uniform building codes based on requirements of results to be obtained not prescribing constructive methods. Laws to permit the speedy assembly of lots into adequate sized units for housing.

Sites — assembled into large-scale units guaranteeing continuity and stability of environments, establishing communities.

Organizations — integrated to create housing, i.e., to plan, to finance, to construct and to manage large-scale housing projects.

Techniques — to determine housing needs, qualitatively and quantitatively; to choose most advantageous sites; to determine the type of housing, the building sizes and heights, the plan arrangements best suited to the individual project; to determine scientifically the best materials and methods of construction for economy and efficiency, i.e., techniques of research, of planning and of production.

The Will — of many vitally interested, including architects, to attack boldly the problems implied in this “list of lacks,” or to support those who are taking the responsibility of advocating measures that will make housing a reality.

For there will be no housing — worthy of the name — until our present shortcomings are eliminated — eliminated by our own collective efforts.

EDITOR
TOWARD THE RECONSTRUCTION OF NEW YORK'S LOWER EAST SIDE

PART I: AN ANALYSIS OF THE EXISTING CONDITIONS

BY

HARLAND BARTHOLOMEW

CITY PLAN ENGINEER, ST. LOUIS, MO.

FOR the past twenty years the well-known Lower East Side of New York has been declining in population and in property value. For about ten years the decline was very gradual, but since 1920 it has become so great as to approach economic collapse. The loss in population from 1910 to 1930 was 53 per cent and the loss in real property values probably greater than this. It has been suggested that Peter Stuyvesant's farm is merely in process of completing a cycle of development and is now rapidly approaching its original state.

Causes of Decline. The principal causes of the decline and present blighted character of the Lower East Side are:

1. Unlimited spread of the city induced by rapid transit and the automobile.
2. Rapid depreciation and obsolescence of existing buildings, due to poor design, inadequate maintenance, lack of modern conveniences, and inadequate standards of light and air.
3. Cessation of immigration and rapid decentralization of immigrants for whom the Lower East Side served merely as a temporary reservoir.
4. Unfortunate reputation of the district due to former overcrowding of the land and practices of exploitation.
5. Removal of the garment industries to other parts of the city.

Same Conditions Prevalent Elsewhere. All large cities are losing population in their older, centrally located residential areas. The decline of the Lower East Side is merely a somewhat more acute manifestation of what is taking place in other parts of New York, or in the centrally located residence areas of Philadelphia, Chicago and St. Louis, or even of the newer cities, such as Los Angeles. While each blighted district is caused by various combinations of conditions peculiar to the district itself, practically all blighted districts have one basic cause in common, i.e., excessive decentralization of the city as a whole or, more simply stated, lack of a well-balanced, comprehensive and official city plan.

Our urban populations have suddenly achieved such a remarkable degree of mobility through the use of the automobile and of rapid transit during the past twenty years that the economic stability of our cities has been undermined. This shifting about is largely a revolt against the undesirable social conditions created by present building practices. Decentralization does not necessarily produce better conditions but is merely a reaction against present conditions — an expression of inherent dissatisfaction and a hope for an improved condition.

Why do most families endeavor to move to the suburbs? Merely because they think they will have more light and air, more pleasant living conditions, and possibly lower taxes and lower living costs. For a while they may achieve such results. They do not realize that when large numbers of other people have done likewise, all will sooner or later find themselves surrounded by much the same old conditions with probably even higher taxes and living costs; for someone will have to pay the costs of maintaining the older areas, and the municipal structure sooner or later becomes top heavy. Decentralization per se is economically unsound and gives no assurance of better social standards, for land subdividers have become no more magnanimous than they were forty or fifty years ago when the older areas were laid out. Most of them merely have a new bag of tricks, although a few enlightened subdividers have come to realize the commercial value of high social and aesthetic standards.

Blighted areas such as the Lower East Side have even greater economic advantages than suburban areas because of their usual centrality of location. There are three great problems to be dealt with in attempting to eliminate the blighted areas, however: (1) determination of their logical character and usefulness in the comprehensive plan of the city; (2) elimination of the obsolescence factor, which can usually be accomplished only by wholesale removal of present structures; and (3) determination of new types of dwellings so designed as to be socially desirable, aesthetically attractive, and economically possible.

Previous Work Done. Several studies and reports of great value, previously prepared, were of much assistance in the present undertaking, notably the Day & Zimmerman Traffic Report (1929), the Board of Transportation's Comprehensive Subway Plan, the Regional Plan of New York and Environ, and
a report of John Taylor Boyd, Jr. and Holden, McLaughlin and Associates.* A most significant and sustained effort for the rehabilitation of the Lower East Side has been performed by the East Side Chamber of Commerce which, over a period of approximately five years, has stimulated an annual expenditure of from one million to one and a half million dollars in the rehabilitation of old buildings.

Organization Interested. The continued decline of the Lower East Side has become a problem of major significance to social and civic organizations as well as to commercial interests. In order to approach the problem in a fundamental manner and to proceed in a thoroughly comprehensive and logical way, the following organizations united to form the Lower East Side Planning Association: Emigrant Industrial Savings Bank, Dry Dock Savings Bank, Citizens Savings Bank, Metropolitan Savings Bank, Bowery Savings Bank, Title Guarantee and Trust Co., New York Title and Mortgage Co., Greater New York Taxpayers' Association, East Side Chamber of Commerce, Henry Street Settlement, Lower East Side Community Council.

Mr. Orrin C. Lester, Vice-President of the Bowery Savings Bank, was elected president of the Lower East Side Planning Association. Under his leadership the work of the association has been aggressively advanced and is becoming widely recognized and understood.

Objects of the Present Study. An agreement was made with the writer's office in October 1931 by the Lower East Side Planning Association shortly after its formation, providing for:
1. Studies of existing uses of property and of traffic conditions, including field surveys and the preparation of various maps portraying the present condition.
2. A comprehensive main and secondary traffic thoroughfare plan.
3. A comprehensive transit plan.

The reconstruction of the Lower East Side must begin with a thorough knowledge of existing conditions, a complete analysis of the factors which have contributed to present conditions, and ascertain­ment of the precise character and development which would be most appropriate in this area as a fundamental part of the comprehensive city plan. This involves not merely a determination of the uses of property, but thoroughfare and transit plans which are essential for the service of the city as a whole; also such supplemental thoroughfare and transit plans as may be needed for local service within the district. Although there was need for a

---

* Report and "Key Plan" published 1930 by the East Side Chamber of Commerce, New York.

New York's Lower East Side. The Manhattan Bridge is in the foreground and the Williamsburg Bridge at the right. The pronounced bend in the East River makes the Lower East Side comparatively independent of the rest of Manhattan.
study of zoning, of parks and of recreational facilities, it was considered advisable to incorporate these as part of a future undertaking so that they might be integrated with more thorough housing studies than were contemplated in the initial agreement.

Procedure. Office space was provided in one of the banking structures within the district. The work was carried forward under the personal direction of the writer and his assistant, supplemented by additional temporary services as needed. Special investigations made included:

1. A traffic count upon all streets.
2. A field check of the uses and conditions of each property, recorded in permanent form and supplemented by thorough analysis of the information obtained.
3. A survey of the actual use of existing street space.
4. An analysis of the amount and conditions of the mortgage on each property recorded separately for each of the financial institutions having large investments in this district.
5. A study of the assessed valuations of land and improvements at approximate five-year intervals for the past 25 years.

Important Findings. The Lower East Side of Manhattan has been defined for the purpose of this investigation as all of the area bounded by East 14th Street, Third Avenue, and the Bowery, Bayard and Market Streets, and the East River. The gross area is 897.6 acres which is 6.3 per cent of the total area of the Borough of Manhattan, or 0.43 per cent of the total city area. The area is physically more or less isolated from the rest of Manhattan Island because of a bend which occurs in the East River.

Three of the four East River bridges deposit their traffic within or immediately adjacent to the Lower East Side, causing unusually heavy traffic flow upon main thoroughfares leading directly to the bridgeheads. Streets are of the usual rectangular pattern, generally 50 and 60 ft. wide, although north of Houston Street the avenues are 100 ft. in width in accordance with the prevailing pattern of Manhattan Island. Because of the comparative isolation of the district, very little traffic was found to use the majority of local streets.

The district is very well served with rapid transit facilities, new subways are under construction and several additional subways are proposed in the Board of Transportation’s comprehensive subway plan. When all of this construction has been completed, this area will possess one of the greatest concentrations of rapid transit in the city. These facilities are more particularly concentrated in the area bounded by Canal Street, Allen Street, Houston Street and the Bowery. There has been considerable abandonment of street car lines and some
new bus line installation. The areas adjacent to the river are particularly in need of more adequate local transit service.

The area is predominantly residential. There are 9,773 buildings, of which 8,079 are tenements and dwellings, 25 elevator apartments, 34 lodging houses, 755 warehouses and loft buildings, 8 office buildings, 130 factories, 275 stables, 44 theaters, and 429 miscellaneous buildings, such as schools, churches, synagogues, and the like. The majority of tenements have stores upon the ground floor. The average height of all buildings is relatively low, 4.54 stories, the great majority of buildings being five stories high. These are chiefly the old law tenements, built in large numbers during the 80's and 90's. They are a more or less obsolete and unsatisfactory type of housing, covering as high as 90 per cent of the lot, and are often in bad repair. They occupy 367.6 acres or 6.3 per cent of the total block area of 579.4 acres.

There are approximately 12,500 stores within the area, of which a total of about 2,000 are vacant. In the last two years store rentals have dropped from $125 per month to $25 per month in much of the district.

Industry occupies only 16 per cent of the net block area, most of which is concentrated along the northeastern waterfront. It is comparatively low in value, and more or less inactive, as evidenced by the small amount of traffic to and from this waterfront. Large areas along the entire waterfront are zoned as unrestricted, and nearly all of the remaining area is zoned for business.

The population of the district was 531,615 in 1910; 416,108 in 1920; and 249,755 in 1930. The 1930 figure represents a decline of 53 per cent from the 1910 high. Population losses have increased considerably during the past ten years as compared with the previous decade. This loss in population has been more or less uniform throughout the entire area. Whereas there was a density in excess of 750 persons per acre throughout most of the district in 1910, present densities are about evenly divided as between the two classifications of 250 to 500 persons per acre and less than 250 persons per acre, as shown upon the accompanying map.

It is difficult to estimate the actual loss in land values. This loss probably exceeds the total loss in population. This, however, is not entirely borne out by the assessed valuations of land and improvements. The total assessed value of land and improvements in 1910 was $300,307,150 and in 1932, $299,832,920. Assessed values have been reduced to some extent in the residential areas nearer the waterfront, but these reductions have been offset by
Figure 5. Major and secondary traffic thoroughfares including those now existing and those which should be widened to accommodate the normal traffic flow within the district increases in assessments of commercial property along main traffic thoroughfares and rapid transit lines.

Conclusions and Recommendations. It is most significant that despite considerable subway construction, numerous street widenings, and a large amount of rehabilitation work, the decline of the Lower East Side has not been arrested. The situation has become increasingly difficult. Mortgage loans have been reduced to about the present estimated value of land only and even these investments will sooner or later be in jeopardy. Over 90 per cent of the property is mortgaged, and consequently the land owners have no means with which to undertake extensive reconstruction work. There are very few holdings by large estates. Two or three large reconstruction projects have failed to exert any effect upon the surrounding property. It is consequently more or less obvious that the conditions of the Lower East Side can change only by alteration of the entire environment which involves large-scale reconstruction rather than any amount of rebuilding on small lots.

Broadly speaking, the area is primarily suited to dwelling purposes. It is now predominantly a dwelling area unfortunately encumbered by obsolete types of structures in bad repair, covering too large a proportion of the lots upon which they stand, and too interspersed with commercial and industrial uses.

Since all main traffic movements are confined to the area west of First Avenue-Allen Street-Pike Street, it is recommended that all through traffic be accommodated upon a system of ten main traffic thoroughfares, including First Avenue-Allen Street-Pike Street and west thereof. The large areas east of First Avenue-Allen Street-Pike Street are peculiarly suited to dwelling purposes, although limited provision might be made for local commercial needs. Traffic access to this predominantly dwelling area could be fully accommodated upon a system of some thirteen secondary traffic thoroughfares which would be widened to 100 ft. at such time as reconstruction might take place.

It is estimated that the system of main and secondary traffic thoroughfares recommended could accommodate a total traffic load approximately 60 per cent greater than the total volume of present traffic flow. This is graphically represented upon the accompanying illustration. The traffic counts show more or less conclusively that the present street pattern is quite unnecessary, even though existing building development presumably adjusted itself thereto. While a certain amount of street space may be needed in addition to the main and secondary traffic thoroughfares, the traffic survey demonstrates that at least 50 per cent of existing local streets could be closed to advantage in any large-scale reconstruction program.

Transit. The district is so well served with rapid transit lines that no important recommendations are made in this respect. It is believed that eventually it may be desirable to consider the operation of a rapid transit loop connecting the downtown, midtown, and uptown business centers, which could also be so routed as to use one of the subway routes in the Lower East Side, using existing subways and the proposed Second Avenue line. This would afford direct connection to all of the important business centers for residents of the Lower East Side.

The recommendations for improved local transit service include further abandonment of street car lines and the establishment of a more comprehensive local transit service in the form of bus lines connecting directly with the downtown and midtown business centers. These bus lines would be so arranged as to afford direct access to all parts of the district and would be routed upon the secondary traffic thoroughfares. Improved service would be afforded particularly to those areas near the river front, which are now inadequately served.

Neighborhood Units. Main and secondary traffic thoroughfares would divide the Lower East Side into 38 unit areas, varying in size from 4.4 to 51.6
Figure 6. Neighborhood units with the areas assessed and their assessed valuations for 1931. These neighborhood units are logically divided by the main and secondary thoroughfares into 38 areas varying in size from 4.4 to 51.6 acres.

acres. The units lying to the west of First Avenue-Allen Street and more particularly between Houston Street and Canal Street are dominantly suited for business development, partly because of the concentration of rapid transit facilities and partly because of higher land values already existing in this area. East of First Avenue-Allen Street neighborhood units as determined by the secondary traffic thoroughfares vary generally from 25 to 40 acres in size. Along the waterfront the total square foot value of land and improvements ranges from about $7 to $10 per sq. ft., and in interior units the total assessed value of land and improvements ranges generally from $12 to $15 per sq. ft., as shown upon the accompanying illustration.

It is believed that these are rather logical sizes for reconstruction purposes in accordance with the principle of more or less self-contained neighborhood units. The size of these neighborhood units is partly the result of circumstances and partly the result of conscious design. Certain of the secondary traffic thoroughfares are logical traffic routes — being
merely the extension of main traffic thoroughfares from areas beyond the district, such as 14th Street, Houston Street, Canal Street and First Avenue. The determination of the locations of other secondary traffic thoroughfares was the result of balanced design in traffic and local transit, particularly since it was found that all present traffic could be accommodated upon the proposed system of main and secondary traffic thoroughfares and still leave room for a 63 per cent increase in traffic, as shown upon the accompanying illustration.

The neighborhood units would be used as a basis for large-scale reconstruction and a preliminary study of one of them was made in consultation with John Taylor Boyd, Jr., architect, in order to determine the practical possibilities of housing construction. The results of this analysis support the contention that it is possible to create in the district a new and superior standard of residence community at moderate rentals. This neighborhood unit would be a self-contained community more or less shut off from the rest of the city, where a considerable population would find harmonious coordination of buildings, local shopping centers, generous open space and park area, school, playground and community facilities. It would also have distinct social advantages. The individual who is lost in the big city could here become a part of a small community with increased incentive for community pride, civic spirit, and loyalty.

Further Steps. Present studies, plans and recommendations were undertaken as the first step in a program of comprehensive reconstruction of the Lower East Side. This first step did not attempt to reach a complete and final solution of an extremely complicated situation. Further disintegration of the Lower East Side cannot be arrested by mere panaceas or palliatives. The roots of the problem are too deeply imbedded in the fundamental economic and social structure of the city to be simply or quickly dealt with. No permanently satisfactory result can be accomplished by a single action, such as a new law, a change of financial policy, a great public improvement, or by ordinary methods of real estate promotion. There must be comprehensive planning for the entire area based on sound economies and high social standards, and there must be concerted effort by each and all of the numerous interests involved — property owners, public officials, financial institutions, building interests, architects and engineers.

Five additional steps are now proposed, several of which can be undertaken simultaneously. It is estimated that within another year it will be possible to initiate construction upon one or more neighborhood units — or demonstrate conclusively that the problem is hopeless. The five additional steps now proposed are:

1. Official adoption of the street and transit plans by the municipal government.
2. Market survey (i.e., determination of the types of housing which could most logically be built in the Lower East Side).
3. Research and plan to determine the social standards and economic advantages possible in neighborhood units of varying size and character.
4. The revision of zoning regulations in accordance with neighborhood unit design; a study of recreational needs not supplied by neighborhood unit design; and certain other basic city planning considerations.
5. Formation of housing corporations to build one or more neighborhood units.

Space will not permit of a full discussion of these proposals or the manner in which they should be undertaken. It is obvious that the present plan should be given official recognition and sanction so that those who undertake reconstruction in the Lower East Side may safely base any detailed plan of neighborhood unit construction upon an accepted pattern.

The experiences of the State Housing Board indicate that there is an almost unlimited demand for good low-cost housing facilities. Where so large a construction program as here contemplated is to be undertaken, however, it would seem advisable to make something of a market survey among employees of the larger corporations and business establishments in the downtown and business centers to ascertain as closely as possible the probable demands for space requirements, rental ranges and allied information.

Our studies have revealed that unusual advantages and significant economies are to be accomplished by neighborhood unit construction. This is an unexplored field. It is believed that extensive research would reveal further economies and aid in determining social standards and numerous other factors which would be of fundamental importance in basic design. Something more is needed beyond the mere repetition of existing housing modes in the creation of a new approach to community life such as is afforded by the neighborhood unit.

While equity money for all types of building processes has generally been available in large amounts in normal times, we are now passing through very unusual times, the duration of which is uncertain. It is believed that reconstruction as here contemplated upon the Lower East Side is an extremely sound investment even today, particularly if entered into upon the basis of a limited dividend corporation instead of just another speculation in building with its attendant compartmented procedure and extravagant costs. The economies which are possible and the quality of the community to be created are dependent upon unified control and wise management. Here is an opportunity for financial statesmanship which necessitates bringing those concerned in city government, in financing, and in designing and building into unified and concerted action.
THE building is of semi-fireproof construction having exterior walls of face brick in Flemish bond, dampproofed and furred. The first floor construction is reinforced concrete joist and terra cotta block. The second floor is framed with steel girders and wood beams. Local marble is used for trim above the first floor level, and granite below. The pitched roof is of green slate, the flat roof of tar and gravel. Windows, dormers, and roof rail are of white pine, the gutters of cypress. The cost of the building, including fees, was $122,000, or .987 cents per cu. ft. The cost per sq. ft. was $38.65

FOUR SMALL RESIDENCES
HOUSE OF ROTHWELL SHERIFF
LOCUST VALLEY, L. I., N. Y.
FULLER & DICK, ARCHITECTS
The main portion of this residence is constructed of cinder block walls with a brick veneer, whitewashed. The service portion has stud walls, stuccoed and painted white. Blue slate is used for the roof, and sheet lead for the main entrance hood. Trim is white painted wood. The living room, above, has painted walls and a floor of herring-bone oak. The library at the left is paneled in butternut and has a walnut floor. Between these two rooms, as the plan shows, there is a radio closet serving both. The hall leading into the dining room, opposite, has painted walls and plank floor.

HOUSE OF MRS. G. T. McQUADE
FREEPORT, L. I., N. Y.
DWIGHT JAMES BAUM, ARCHITECT
This small frame house, with a cubage of 30,850 cu. ft., employs the familiar 4 in. stud construction. It is built on a concrete foundation and has a waterproofed basement in which there is a large room used as a laundry and game room. White painted shingles are used for the sidings and weather-stained shingles for the roof. The house is oriented to take full advantage of the location and shape of the lot, with a large living room wing, a separate service wing, and the two-story central portion. Requirements of the owner were carried out in such features as the large entrance hall, the enclosed porch, the unusually large living room, and the location of the master's bedroom wardrobe adjacent to the bath. The cubic foot cost of the house was approximately 70 cents.

PERSIAN ISLAMIC BRICKWORK

Almost unknown in the detail of its design and technique, the brickwork of Persia offers a new source of inspiration to the architect of today. The illustrations in this article have been reproduced from a series of photographs through the courtesy of the American Institute for Persian Art and Archaeology

BY

MYRON BEMENT SMITH

PERSIAN brickwork, technically the most amazing that has ever been produced, deserves, and sometime doubtless will receive, a careful study at full scale in the manner of Nathaniel Lloyd's masterly book on English brickwork. It is surprising that so important an art has been studied so little.

Due to Persia's present geographical isolation, and the long directed attention of historians on Rome for the origins of medieval forms, the architectural contributions of Persia have been recognized by but few scholars other than Strzygowski. The history of Persian architecture has not been written, and in the field of specialized study little has been produced other than the excellent survey of certain monuments made by Professor Sarre and his assistants, the monographs on the Khorasan district by Professor Diez and the studies of Captain Creswell on the Persian origins of the double dome. With scores of monuments yet to be discovered, the field is ripe for some A. Kingsley Porter to do for the Islamic architecture of Persia what that brilliant scholar did for Lombard architecture in Italy.

The tradition of brickmaking in Persia is not new; it is quite possible that brickmaking was invented on the Iranian plateau. Archaeologists now know that it was people from highlands in that direction who took the arts with them to Sumer, and that the Sumerians in turn took them on to found the civilization of Egypt. Coming down to historical epochs, the glazed and molded brick reliefs of Susa, notably the frieze of archers, are familiar to all who visit the Susanian gallery of the Louvre. They are part of the tradition of Persian masonry architecture, one of heavy walls of sun-dried or baked brick, incrusted on the exterior and interior surfaces with baked brick, faience or stucco.

In the Islamic period, this building tradition

The Sareban Minaret in Isfahan, built in the Fourteenth Century, which illustrates the Persian method of dividing the shaft into zones by varying the pattern of brick
Above is a view of the vaults in the Jami Mosque in Isfahan, which was built probably in the Ninth Century. The Jami Mosque is noted particularly for the variety of geometric patterns used in its vault construction. Below is the Mosoleum of Baba Ghasem in the same city. It was built in 1239 A.D. The detail presented here is a niche showing cusped brickwork laid in an intricate herringbone pattern, an early form of stalactite vaulting.

Persisted. Under the Seljuks (A.D. 1037-1194), faience incrustation in glazed tile and faience mosaic was developed to a degree of perfection never since equalled. In the later Timurid period (A.D. 1369-1500), bold decorative schemes of plain brown bricks, juxtaposed with colored enamel bricks, were used in conjunction with faience mosaic. To this era belongs the famous Blue Mosque of Tabriz. Under the Safavids (A.D. 1502-1736), it became the custom to sheathe the exterior of the domes with either mosaic faience cut from slabs, or with copper plates heavily surfaced with pure gold. Modeled stucco, and painted stucco in imitation of polychrome faience, were used with the brickwork revivals.

No impression of Persian brickwork would be accurate without mention of the polychromy of tile and mosaic faience in conjunction with which the terra cotta color brick was so often combined. In the Safavid period, a background of deep cobalt blue was almost universal. Against this color was employed an intense turquoise blue, light emerald green, fawn color, pure black, clean white and
An unusual view of the vaults adjoining the great dome chamber in the Jami Mosque. The Persian feeling for variety in pattern is no better illustrated than in this almost confusing series of courses and inlays. Below is a detail of the portal to the Sanctuary in the Jumeh Mosque in Varamin, which was built in 1322 A.D. The panel at the left, illustrating a typical treatment, is in polychrome faience, chiefly turquoise and dark blue.

clear golden yellow. Because of the accidental variations in firing, the individual colors were pale in some areas, deeply intensified in others.

Due to the nature of the Persian method of building, it was natural that the decoration of the surface should become an end in itself. Walls were divided into bold panels, often carried to such an extent that Persian architecture has been referred to as a paneled style. This scheme of decoration contributed to the development of the brickwork, which was used, either by itself or in conjunction with other materials, both to frame the panels and to fill the fields enclosed.

Beginning with the mortar joints, it will be noticed that these were often deeply raked, generally with emphasis on the horizontal. Occasionally a pattern was made by raking certain joints or by treating two bricks as a single unit, the joint between being minimized and flush. The next development was to make bolder patterns of diapers and frets by sinking certain bricks to a plane below that of the wall surface. Both of the above were expedients to break up the flat surface,
This tomb tower at Varamin was built in the Twelfth Century. The Kufic frieze and roof cone are in bright blue faience. The faience incrustation in glazed tile, as shown here, reached its highest development in this era.
One of the more familiar types of honeycomb patterns found in the vaults of the Jamī Mosque in Isfahan.

Another vault in the Jamī Mosque, with a less intricate herringbone pattern than the other vaults.

to "let air into the wall," to make it appear less heavy and solid. Another means to this end was the introduction of terra cotta plugs, generally in the vertical joints. These plugs were impressed with geometric designs, and being of fractional dimensions of the bricks, they not only lightened the effect of the wall, but also gave the bricks scale, and due to their lighter tone, produced a mild play of color. Polychromy by the use of glazed and unglazed bricks was resorted to extensively in the Timurid period, notably at Samarkand.

The ornament of the earlier minarets was effected by dividing the shaft into zones by means of elaborate bands of brick pattern, often combined with Kufic inscriptions worked out in the same material. Each of the zones was then treated with a different form of brick mosaic, or diaper, in two planes.

Brick mosaic was often used in complicated vault and dome construction, as in the Jamī Mosque, Isfahan. All possible variations of herringbone pattern were employed, the terra cotta plugs were used in various ways, and larger pieces of terra cotta inlay were occasionally inserted. In the more intricate vaults, the field was divided with a honeycomb pattern or broken up with rudimentary stalactite cusps.

A highly ingenious technique of the Persian bricklayers was that of brick and stucco mosaic. Bricks were laid on edge in geometric patterns, while the space between them was filled with mortar to give a second surface on a sunken plane. This technique was not peculiar to Persia; it was used in practically the same way in Byzantine structures, notably at Mistra. A fine example is the mausoleum of Mumine Chatun at Nachtschehan, northwest Persia. The sunken surface of the plaster was pricked, stamped and modeled, while the bricks themselves were glazed in polychrome.

Interior of the dome in the Mausoleum of Baba Ghasem, showing the often used cusping in a herringbone pattern.

Another illustration of cusping, this one taken from the Jamī Mosque. The center inlay has been destroyed.
Above is a view of the dome of the Sanctuary in the Jumeh Mosque in Varazmin. The construction of the squinch, similar to the one shown below at the left, is typical of Fourteenth Century work. Below the squinch the Kufic characters spell a verse, probably from the Koran. At the bottom right is a detail of the southeast archway in the Jami Mosque, which although more elaborately patterned than the brickwork of today, is simple in comparison to the other examples shown. The squinch at the bottom left is in the great dome chamber of the Jami Mosque, Isfahan.
STATE LIBRARY AND HISTORICAL BUILDING
INDIANAPOLIS, INDIANA
WINNING DESIGN BY PIERRE & WRIGHT, ARCHITECTS

The illustrations on this page are of the winning design in the recent competition for a State Library and Historical Building for the State of Indiana. Pierre & Wright, whose design is reproduced here, were the winners of the first prize and have been retained as the architects of the building. The program called for a fireproof structure to contain 1,380,000 cu. ft., and to house the State Law Library, the archives of the Historical Commission and the William Henry Smith Memorial Library. The jury consisted of Edgerton Swartout, Raymond Hood and J. C. Ferguson, the librarian of the City of Brooklyn.
THE annual competition for the Rotch Traveling Scholarship was won by Carroll Coletti of Quincy, Mass. There were nineteen original entrants for the scholarship, and after the preliminary competition seven competed for the final award. The program called for a commemorative monument at the end of a basin and the drawings submitted were judged by a jury consisting of F. Ellis Jackson, William G. Perry and Henry R. Shepley. The program was built around a recent competition for the Massachusetts War Memorial. The first award of $3,000 made to Mr. Coletti carries with it the opportunity of two years' study in Europe. Mr. Coletti has had architectural experience with J. D. Leland & Co. While working in this office he attended the Boston Architectural Club and entered the Yale School of Architecture in 1928. He was the winner of the Intercolligiate Collaborative Problem, 1931, and was graduated from Yale the same year.
AN EXCLUSIVE ARTICLE ON THE PRODUCTION PROGRAM OF GENERAL HOUSES, INC. . . . AN INDUSTRIAL APPROACH TO HOUSING, BY IRVING H. BOWMAN . . . WHAT MAKES HOUSING RENTAL? BY EUGENE KLABER . . . ARCHITECTURAL FORUM DATA AND DETAILS OF SMALL HOUSE SPECIAL EQUIPMENT
THE living room of "K₂H₄O", a product of General Houses, Inc. This interior is not essentially different in appearance from other small house interiors though frankly acknowledging its panel construction. But the formula implies the application of industrial science to the dwelling as a unit of a coordinated housing scheme in which house, lot and neighborhood are considered as elements of an integrated pattern.
A PRODUCT OF GENERAL HOUSES

As constructive measures in the solution of the housing problem The Architectural Forum has advocated better land control, better planning and construction, cheaper financing, revised laws, large-scale production. Presented here for the first time is a coordinated plan that includes a prefabricated house as a unit of an integrated housing program.

Until very recently the architect's concern with the tremendously complicated question of housing has been generally limited to the planning of custom-built houses and the problems of their construction in terms of current practice. With such projects the questions of general economics, land control and social welfare were relatively unimportant. Increasingly, however, attention is being given to the larger problem of housing. Now these questions loom large in the architect's field of interest, for they condition every attempt to solve the problem of providing adequate living space and equipment at a price within the means of the average wage earner or the worker with a small income.

The problem as a whole is in reality an aggregation of many separate problems which affect and are affected by the entire current economic, social and political order. Their complications are not generally realized and their extensive ramifications cannot be explored without analysis and painstaking investigation. Some of this work has already been done; much is still in progress. But a few organizations and individuals have reached conclusions and are now ready to produce their concrete evidence.

Among them is General Houses, Inc., (an organization first described also in the current issue of Fortune), which, as a central coordinating and merchandising company, working in close cooperation with a group of outstanding building manufacturers, has for its avowed objective not merely the planning and construction of houses but the production of housing in the fullest implication of the term. The function of General Houses, Inc. in effect constitutes the integration of many now isolated elements of the building world toward this end. It has written for itself no specific program beyond this. Its initial approach to the entire housing problem is merely a reflection of its proposal to develop adequate, economical conditions for living in terms of immediate and progressive practicality. In this proposition the house itself is regarded as merely one detail of a large and complicated pattern, incomplete without the proper correlation of land control, social sufficiency and individual satisfaction.

The commodity of General Houses, Inc. is this
pattern: land in a planned, developed and controlled community; a fireproof, prefabricated dwelling, equipped with every item of modern necessity — even perhaps to the furniture — a wide range of individual choice — and a plan of financing to make it easily available. Behind the commodity itself lies the capacity of the organization to supply, in addition to its executive services, national advertising, architectural and engineering direction, legal counsel, credit facilities and the expert advice required in matters of landscape architecture, group planning, domestic science, interior decoration, etc.

Without minimizing the importance of such problems as land utilization, labor mobility, taxation, installment financing, etc., the attainment of the objective which General Houses, Inc. has set forth will depend largely upon the technological development of the dwelling. The company does not deny the importance of large-scale building operations as applied to the multi-family structure. It is convinced, however, after much study of the problem's various phases that at present the small single family house not only offers the best field for immediate development but also fulfills most completely the needs and desires of the average American family of modest means. But it must not be construed that General Houses, Inc. is committed to any one set of types or will confine itself to any arbitrary series of designs. Its objective is housing — a continuing necessity — and if tomorrow develops improvements over today's house, that same tomorrow will find new models ready to be bought at every market agency in the nation-wide network of distribution that General Houses, Inc. contemplates.

This, however, is the future. Present plans are definite and a series of houses is now being developed based upon the various assemblies of factory-made, standard units, parts and equipment. Mass production has made possible a construction that is economical to produce, simple to build and is adaptable to a variety of uses. Varying site and size conditions may call for different types of dwellings and the structural system combined with the other elements of standardized planning may be used in row or multi-family structures as well as in double and single houses.

In its July issue Fortune publishes a full account of the organization and activities of General Houses, Inc. In this brief article it is possible to describe only the corporation's plans for immediate production — small, low-cost, high-grade, factory-fabricated houses — and to touch upon the proposed method of distribution and finance.

The Problem of Design. Although the prefabricated construction imposes standard structural units, it permits also a wide choice of arrangement with a heretofore unknown efficiency of field erection. General Houses' present list of standard small house models includes eighteen layouts, which with their similar basic equipment vary chiefly in size and room arrangement. The plans are the product of much study and have been based generally upon apartments of demonstrated success. Rooms are grouped about a central hall giving a maximum of privacy within a minimum of space. Bedrooms have been planned as small as is practicable, to make possible a large living room. In most instances the dining room has been eliminated and a portion of the living room set aside to serve its purpose and in the larger plans the kitchen equipment has been ar-
This house, designated as Q-H 4, will be fabricated and erected at A Century of Progress Exposition in Chicago in 1933. It will be completely equipped and furnished and will be a model illustration of the General Houses' standard for its program of immediate mass production.

ranged to make possible a dining alcove. The utilities have in each case been grouped together thus saving space, material and also labor during equipment installation.

Normally the houses have no basement, necessitating an outside storage room for trunks, garden implements, etc. Normally also the small houses are only one story high. Neither of these two conditions was arbitrarily set. A basement appeared unnecessary and costly, though when conditions make it desirable it easily may be built of concrete. The grouping of rooms on one floor results in a house of low-lying, small and rambling proportions, a desirable thing as viewed by General Houses, Inc. Aside from these facts a one-story house with no basement produced an economy by eliminating excavation and saving the space which would be necessary for a stair well. Economy also was the primary reason for omitting an attached garage, for the cost of a detached, uninsulated garage is low in comparison and the corporation considers it adequate to the purpose.

Many plans have been developed by Howard T. Fisher, architect and one of the active organizers of
DETAILS OF PREFABRICATED CONSTRUCTION. HOWARD T. FISHER, ARCHITECT

Isometric views of construction details and their assembly as developed by Howard T. Fisher, architect for General Houses, Inc. The units are susceptible to industrial mass production but have been designed so that their field assembly is a simple matter. The exterior panels are pressed from steel sheets. Insulation is in the form of rigid slabs.

General Houses, Inc. These plans are conceived in terms of immediate production possibilities and are only a first step toward what their designer sees as the ultimately ideal dwelling. Typical of the average size standard types are the illustrations at the beginning of this article and those on page 67. The latter illustrate a house — designated as QH 4 — which will be fabricated and erected at A Century of Progress Exposition at Chicago in 1933. Completely equipped and furnished, and set in the center of a landscaped plot, it will illustrate the scope of purpose behind the activities of General Houses, Inc.
Construction. Every detail of the structural system has been studied to permit economical mass production, to develop simplicity of field assembly and to assure adaptability to a variety of building conditions. Briefly, the construction may be characterized as a panel system in which isolated elements of support are lacking. The forms of the panels developed as a result of reducing construction units to their simplest terms to permit their interchange to suit a variety of designs. The other parts of the construction, including the means of field assembly, were designed not only for the highest efficiency in use but also to avoid special and unusual methods of field erection, making it possible to utilize already available building trades.

The foundations and rough floor do not depart from accepted practice except in the construction methods employed. Both are of concrete and are poured at the same time. The walls are 8 in. thick, and the floor, poured over a 6 in. cinder fill, is a 4 in. slab reinforced with wire mesh carried over the top of the walls. The latter contain anchor bolts at the proper spacing for connection to the wall panels. The pouring of the concrete is expedited by the use of standard self-aligning forms which can be re-used indefinitely. The tops of the forms are leveled to act as a screeding guide for both the concrete and cinder fill and contain jigs for securing the anchor bolts and to assure the proper location of the heating pipes, which are imbedded in, or under the floor slab. These forms save the cost of field layout and eliminate the necessity for batter boards, lines, etc.

To insure rapid progress an accelerator is used in the concrete, making it possible to start erection of the wall panels about 24 hours after the mixture has been poured. Integral waterproofing is also used in the slab.

Although this type of foundation and floor requires more field work than a prefabricated construction, it is entirely satisfactory. The alternative is a structural steel floor which would have to be carried on beams resting in turn on isolated piers. Although this system would require no stripping; and practically no digging or back filling, it is somewhat more expensive.

The finished floor is laid after all other parts and equipment of the house have been installed. It consists of 2 ft. squares of laminated wood attached to a 2 in. thick slab of insulation. The flooring is completely prefabricated even to the finish of the wood and is cemented directly to the concrete floor slab with a thin coating of a cold asphalt compound. After the foundation is in place the unloading and erection of the pressed steel panels is accomplished by a gasoline-operated crane unit, equipped with a caterpillar tread. A crew of only four men will be needed to erect the outside of the building. The time required to set the panels, with the subsequent truing up and tightening, takes less than eight hours.

Before the roof is put on all the plumbing fixtures, the heating plant, all millwork, etc., are unloaded from trucks and set inside the house by the crane, in this way doing away with much of the usual hand labor. After the roof units are set (also by the crane) the exterior of the building is completely finished, with the possible exception of glazing and a final coat of paint.

There are four types of exterior structure panels. One of them is a roof panel, furnished in various lengths adapted to standard plans. The others
The three plans above illustrate the adaptability of the panel system of construction to various house sizes and layouts, all of which have been designed to include the best features of successful apartments. Below is one of the standard plans.

The pressed metal panels are fitted with rigid slabs of insulation, the surfaces of which have been treated to provide the finished interior surface of the wall. The insulation is not fitted to the panel in the factory and shipped complete in one unit for two reasons. The first is the difficulty of providing a practical, easily secured link between the panels. With the panel delivered to the building site already fitted with insulation and an interior finish any ordinary method of joining them by bolts would not be possible. Experiment demonstrated the fact that other methods were cumbersome and would off-
The "Cadillac" or "Lincoln" house may also become an item of General Houses' future production program. The structural system employed in the small models is adaptable to large houses as well as to those developed from the plans opposite

set, by loss of time on the job, the advantages which the fabrication of a complete panel unit might secure. Secondly, the weight of the panel, plus its insulating slab would make it a more unwieldy thing to install with the attendant possibility of damage to the interior finish.

The interior partitions are prefabricated in standard 4 ft. widths of a material similar to the wall insulation. They are entirely prefinished and are set with joint strips similar to those used in the exterior walls. At the walls, floor and ceiling they are secured by a simple system of adjustable channel clips, making their installation a quick and simple matter. The interior doors are set complete with frames at the same time as the partitions are installed, and are secured to the floor and ceiling with simple T-bar stiffeners.

The finish of the ceiling is similar to that of the walls, though in either case the matters of color, applied surface texture, etc., can conform to the varying tastes of the owner. The ceiling is paneled with squares of insulating material with the joints covered by T-bars similar to those in the partitions and exterior walls. The ceiling slabs are kept in place by a strip attached above at the juncture of the structural roof panels and fastened to the supporting T-bar below.

The structural roof is formed of pressed steel panels generally similar in form to the exterior wall panels but stiffened in the center by a small I-beam tack-welded to the panel plate. Their width is the standard 4 ft. but they are fabricated in varying lengths to accommodate the different spans of several standard house plans. The ends of each panel are flanged to form an attachment to the top of the wall units. They are attached to these and to one another by wedge bolts. Watertight gaskets (or a mastic caulking compound) are used between the panels, thus making an impervious exterior surface. The structural roof is not covered by a membrane surface, but is painted with aluminum paint or covered with aluminum foil to reflect the heat of the sun. The edges of the roof are finished with a low curb of pressed steel plate and the surface is drained by an interior downspout.

Although most of the small houses developed by General Houses, Inc. are one story in height, the strength of the wall panels makes it practical to use the structural system for a two-story building. In this case the second floor construction would be similar in all respects to that of the roof. The roof panels have been designed to support a live load of 30 pounds.

Equipment. The small houses developed by General Houses, Inc. are, in effect, built around a core of utilities, which includes the kitchen and bathroom, the heating plant, and the major outlets for electric and gas services. All utility lines are contained within the partition that separates the bathroom and kitchen, thus eliminating long and expensive runs of pipe and affecting a very large
item of expense due to the savings in material, time and labor of installation.

The basic equipment units are standardized throughout, and although their relative location depends somewhat upon the room arrangement of the house, in all cases they occupy a central place in the plan. Contrary to the rule in many small houses every unit has been selected for its special use in a small house. The bathroom in particular is the final result of much study to produce not only the most compact arrangement of fixtures but the highest efficiency of the units themselves. The principle of prefabrication has been applied here as well as to the structural system of the houses. The fixture units will be pre-assembled by General Houses so as to become an integral part of the bathroom wall which, when installed, requires only an attachment to the floor, ceiling and adjacent wall panels. The units thus assembled contain within themselves all necessary traps and fixture connections. Their complete installation requires only the routine connection to the soil stack and service lines. A medicine cabinet is furnished as an integral part of the lavatory unit, and a linen closet is installed over the clothes washer located in the bathroom.

On the opposite side of the bathroom partition is the complete installation of the kitchen equipment with units which have been especially designed to provide the maximum of utility and will become standard for small houses of this type. The equipment is arranged to save time and labor in kitchen work. Against the bathroom wall is a double-compartment sink with, in most cases, a built-in range adjacent. A complete kitchen cabinet and an automatic refrigerator are installed on the opposite wall. Included also are china cupboards, built-in vegetable compartments and a broom closet. Near the entrance door a coat closet is provided in all plan types. Wardrobes are used in the bedrooms, first, because they save space, and, second, because they offer a more efficient storage compartment than the more usual closet.

Coal storage has not been provided, as it is anticipated that either gas or oil will be used for fuel. The house is heated by an automatic circulating hot water system. Radiators are supplied by pipes under or in the rough concrete floor. The system is controlled by a thermostat located in the living room and an aquastat at the heater. Hot water, of which there is a constant supply, does not circulate to the radiators until a drop in temperature makes heating necessary. Then the thermostat starts an electric circulator which supplies heat to the radiators throughout the house. When a normal temperature is attained, the thermostat breaks the contact and the circulator stops. In a gas-fired system the boiler capacity is selected to produce comfortable interior temperatures under average weather conditions. In abnormally cold weather a side-arm heater, installed as part of the plant and controlled automatically with it, may be lighted to increase temporarily the heating capacity of the plant. This arrangement insures an unfailing and economical supply of heat, and saves the cost of a larger heater as well as the cost of the additional space necessary for its installation.

Distribution and Financing: Though the products of General Houses, Inc. may become standardized commodities comparable from the manufacturing viewpoint with the automobile, they are sold, of course, for a permanent attachment to land. And though a wide public acceptance of the houses may well attach to them a constant value, shifting land costs due (at least in part) to a lack of planning and control have led General Houses to a land stabilization plan as part of a distribution program in its production of housing.

It proposes through distributors to sell the houses with land in an area developed locally in accordance with a master plan prepared with the cooperation of the company's experts. The tracts would be locally administered by the distributor and controlled — at least during the payment stage — by General Houses itself. The company also sees, in certain cases, the possibility of retaining actual ownership in itself or an affiliated organization, renting its houses under lease rather than selling them. Houses will also be sold without the land to purchasers owning outright a suitable lot. General Houses, however, is well aware of the seriousness of the land situation and from the standpoint of security and for the mutual advantages that land control implies, prefers, in marketing its commodity, to control the land developments.

The sales of the houses will be financed by distributors through an affiliated organization. In the early stages of mass production a standard small house with equipment will sell for approximately $3,500, exclusive of land or furnishings. It is anticipated that this price may be reduced by $1,000 as production increases.

It is proposed to eliminate the distinction between first and second mortgages and to make the sale of a house as simple a matter as the sale of an automobile, considering the influence of the land involved. When a buyer already owns a suitable lot, General Houses will sell the house without down payment for approximately $30 per month. Financing costs are estimated at $ per cent, interest will be 6 per cent and the payments will extend over a fifteen-year period. Where housing is sold in one of the company's controlled developments, a down payment will be required. The payment will vary according to location and will be equivalent to the value of the land as determined by a prorated cost of development, financing charges and the profit of the distributor.
THAT the wide public acceptance of small houses does not constitute a solution to all phases of the housing problem is well recognized by the writer. Equally as well recognized, however, is the general need for small houses which are less expensive, more efficiently equipped and more rationally planned as to space and structure than those at present available to the American family of modest means.

The following paragraphs with their accompanying illustrations describe our efforts to reach a solution not only to the design problems of the house itself but to those of structure, manufacture, erection, finance and sales.

The Problem Analyzed. The difficulty which the ordinary family finds in the present system of house building and ownership is largely an economic one. It is evident that even an excellent solution to the technical problem of the house does not necessarily guarantee to the home buyer a sufficient increase in benefits over the traditional type. The finished house is only one of many items which, combined, form the housing system. The method of its manufacture, field erection, financing and maintenance are of equal importance. Each of these points constitutes a problem in itself which can be solved only by predating a solution upon the simplest technical organization of the house itself.

It should be noted that the houses presented here-with are not offered as solutions to the problem of the minimum-income shelter. The reason for this is two-fold. The building industry is not sufficiently integrated at the present time to produce a single house within the reach of the average income—which has been variously estimated as between $1,200 and $1,800 per year. Secondly, families with such incomes appear to be more economically housed in multi-family dwellings than in single houses.

Our effort has been to produce a dwelling for the family with standards of individual and community living somewhat above the average; with an income between $2,000 and $3,500 per year; a family which can afford to own a home costing from $6,000 to
From elevations and floor plans for three different types of houses ranging in cost from $4,000 to $6,000. The elevations at the top correspond with the floor plans directly below, and are not elevations for the same house. Each of the houses is similar in construction, the only changes being those necessary in plan and space provision for the accommodation of the varying needs of the families, with incomes between $2,000 and $3,500, for which they were designed.

$6,000, exclusive of the land, and which demands in that home a higher degree of excellence and efficiency than it can obtain in present houses for a similar cost. From a technical standpoint, this combination of requirements presents a problem that is incapable of solution by the present system of small house construction, a fact adequately attested by the failures of many worthy attempts. An entirely new approach was a necessity, and in order to secure economically all the desired advantages, the house has been planned in every detail for industrial mass production.

Shop fabrication of houses is entirely a new field for an industrial plant. In order to avoid an excessive tooling cost to the manufacturer, with a subsequent high cost to the purchaser, it was necessary not only to design every detail for existing materials which were easily obtainable and easily worked. It was also necessary to fabricate them into forms which would serve the purposes of the problem and yet make unnecessary many new industrial tools.

These limitations have had a definite influence upon the selection of materials and upon the type and size of the house units to be fabricated in the shop. Due to the fact that the houses are designed for a national market and may be shipped long dis-
tances, light-weight structures were necessary. The limitations of present trucking facilities determined the maximum size of units, and the method of their field assembly had an important bearing upon their actual design.

**Plan and Design.** The houses illustrated in detail are only three of several schemes which will be manufactured and sold as standard models. Each has been planned for the general requirements of the "above-the-average" family. Although the houses differ from one another in arrangement, their essential difference is in space accommodations and equipment.

Type 1 was designed for a family of two adults and two children with an income of approximately $2,000. It is assumed that they own an automobile (an assumption common to all types); that, due to a limited income, their home life is not elaborate; and that their requirements will be served by combining the living and dining rooms and by providing only one bathroom.

Type 2 was designed for a family of the same size but with a higher income, accustomed to a more elaborate family life and requiring a separate dining space, a recreation room, and an additional bathroom.

Type 3 was designed for a family of two adults and three or four children, of which although their income is higher than that of the family assumed for the first type, must necessarily live as simply. Although a family with three or four children might well utilize more than one bathroom, it was omitted for the sake of economy in this instance.

The design of all three types was based on the omission of a basement and the location of the laundry, heating equipment and garage on the ground floor. The basement was omitted because it has outlived its usefulness in modern life. It is expensive and serves no purpose that cannot be more efficiently included elsewhere. This omission gave added privacy to the living quarters on the second floor and also a freedom from ground dampening, which eliminates large wall columns and gives an unobstructed interior space. This type of stair made the utilization of the roof area a practical feature.

The equipment in each type of house is standard throughout and in most instances is an integral part of the plan. The wardrobes in the bedrooms contain a chest of tray-type drawers, thus obviating the need for a chiffonier in each bedroom. The kitchens are kept at a minimum and the equipment arranged on one wall to save not only space but also effort in the preparation of meals.

**Construction.** The influences most effective in developing the plan and design were also most influential in determining the structural system and its assembly. The objectives of the structural design were economy, ease of fabrication, transportability, ease of field assembly, lightness, permanence and strength. The houses are designed structurally about the stair tower, which is built in the shop in one piece and forms the main support of the house. From the top of the stair tower, light-weight steel trusses support the mullions in the exterior wall construction, which in turn support the floors.

The spaces between the webs of the second level floor units are utilized as air conditioning ducts. The heater and the air-cooling mechanisms (the cooling is accomplished by a circulating cold water system) are centrally located on the ground level and are connected directly with two sets of ducts. All vents are in the floor of the second level and in the ceiling of the first. Although the latter have not the efficiency of those on the second level, they assure temperatures satisfactory for garage and laundry spaces.

The interior partitions are non-structural and are anchored between floors in a manner that makes them easily removable, if desired. The exterior wall panels have an all-over thickness of only 3½ in. and are extremely light in weight and easily handled.

The exterior wall units consist of steel stampings 6 ft. long, 4 ft. wide and 3 in. deep, insulated and fireproofed with a 3 in. slab of aerocrete, precast with a wire mesh reinforcement, and cemented to the steel stamping. The aerocrete is precast in a metal mold and then faced on the interior with decorator's muslin. The entire unit is then dipped in paint.

The window units are of two types, fixed and operating. The operating sash of extruded aluminum slide horizontally in a roller-bearing track. Since much of the exterior of the house is of glass, all windows are double glazed with a 3/8 in. dehydrated air space between the glass sheets. The dividing strip between panels is of phenol composition, sealed in place with a transparent, inorganic agent.

All the equipment in the kitchen is contained in one large section, 12 ft. long, 8 ft. 6 in. high. It includes an electric refrigerator, a range, sink, Receiving, and the necessary dish and utensil storage.

(Continued on page 78)
STANDARD CONSTRUCTION DETAILS FOR PREFABRICATED HOUSES

Although these details have been selected from the plans of the No. 2 house, they are standard in all types. Applications have been made for patents for all those details which were designed by Bowman Brothers, architects.
CONSTRUCTION AND EQUIPMENT DATA

FLOOR UNITS
The floor units are composed of a pressed or rolled sheet metal web system, spot-welded to top and bottom sheet metal plates. Standard units are 12 ft. wide, 28 ft. long, and 6 in. deep. Fireproofing is provided by a phenolic composition surface, and hung with bolts to the under side of the floor units. Insulation board 2 in. thick is laid on top of the decks as a sub-floor and for sound-deadening. Insulation board 6 in. thick is laid on top of the decks as a sub-floor and for sound-deadening. Aerocrete, 22 pounds per cu. ft. density, is used for insulation between the plates of the ground and roof floor units. The second floor units are hollow, the space between them being used as a duct system for heating and air conditioning. Large precut sheets of linoleum form the finish floor.

EXTERIOR WALL UNITS
The wall units consist of 20 gauge steel stampings, 6 ft. long, 4 ft. wide, and 3 in. deep, with steel channel reinforcements at top and bottom. Tubing mullions, 2 in. square, are bolted to the spandrel channels of the floor units at top and bottom. They are located on 5 ft. and 6 ft. centers, with T-shaped tongues tack-welded to the sides of each to receive the grooves in the wall units. Insulation and fireproofing are provided by a 3 in. slab of aerocrete, which is precast with wire mesh reinforcement and cemented to and compressed into the steel stampings. For interior finish the smooth surface of the aerocrete is covered with decorators' muslin and the entire unit dipped in Du-lux paint. The exterior joints between the units are filled with an elaterite caulking compound and depressed so as not to drip when heat expands the units.

WINDOW UNITS
Windows are of two types, fixed and operating. The latter slide horizontally in a track on roller bearings, and are of extruded aluminum, the track of bronze, and the roller bearings of nickel. The fixed sash are of phenol composition. All sash are double-glazed with a ½ in. dehydrated, sealed air space between the panes. The sash are designed with interlocking weather breaks.

PARTITIONS
The interior partitions are constructed of a core of insulation board, ½ in. thick, and finished with a phenol composition prepared surface that is cemented to the core. Partition units are 3 ft. wide and 8 ft. 3 in. high. The units slip into a groove provided in the rock wool board on the under side of the ceiling units. They are supported by a rolled metal baseboard, which is a continuous wireway of 14 gauge blue annealed steel, grooved to receive a micarta or bakelite removable baseboard which contains the electric base receptacles at 6-ft. intervals. There are no chases in the partition units themselves for wires, since the partitions are movable.

KITCHEN UNITS
The electric refrigerator, range, sink, Receivador are combined into the dish and utensil storage cabinets as an integral part. The cabinet works is built of heavy gauge metal in sections 12 ft. long and 8 ft. 6 in. high. The Receivador is the top of the dumb-waiter which has a package door at the ground level for deliveries. Standard finish for all metal is a Du-lux coating, white in color.

BATHROOM UNITS
The bathing facilities are a combination tub and shower, constructed of galvannealed sheet steel, dipped painted. It is similar to a large shower, 3 ft. x 5 ft., with a curb 17 in. high to permit its use as a tub. Until mass production permits the use of glazed doors, waterproof curtains will be used. The lavatory is of stamped stainless steel, a non-integral spout and compression type valves. The toilet is of a type now standard.

HEATING AND AIR CONDITIONING
Equipment for heating, cooling, ventilating, and humidifying is located in the first floor level, adjacent to the stair tower, and is connected directly with two sets of ducts to vents in the floor of the second level and the ceiling of the first. The 6 in. space between the floor plates is sufficient for accommodation of the ducts. Temperature and humidity control are thermostatic. The air is cooled by passage through a cold water coil rather than a refrigerating unit, and is also passed through an ozonator for purification before being recirculated. Heating equipment may be either gas-fired or oil-fired with no difference in cost.

Another view of the model shown on page 73, this one looking down upon the incom­
pleted hood. This house was designed for a family of two adults and two children
having an income of approximately $3,500 a year, and with standards of living that
demand a separate dining space, a recreation room, and an additional bathroom

cabinets. The unit is built entirely of metal, the
Receivador being the top of a dumb-waiter, which
has a package door at the ground level for deliver­
ies. The units are not finished with the usual baked
enamel but are spray-painted, making refinishing,
when necessary, an easy matter.

The bathroom is not installed as a completely
fabricated unit, but is assembled on the job from
standard units. Since tub bathing is often necessary
in times of illness, this facility is combined with the
more usually desirable shower bath. The combination
bath and shower is stamped from sheet steel, is
spray-painted, and is similar to a large shower stall.
It measures 3 x 6 ft., and has a 17 in. high curb, per­
mitting its use as a tub. The toilet is of a usual type
and the lavatory is of stamped, stainless steel.

Field assembly is simple. A foundation hole is
dug for the stair tower and the bottom leveled off
with a mass concrete slab, thus equalizing the soil
pressure. The stair tower, anchored to the concrete
by a grillage frame, is then erected by derrick, and
the light steel trusses hoisted into place and bolted
to it. Next, the steel hanger rods are bolted with
clevises to the trusses and the mullions for the
second level wall construction bolted to them.
The roof units are then hoisted into place and bolted
to both hanger rods and stair tower. The second
level floor units are erected in a similar manner,
followed by the assembly of the first level mullions
and floor units.

Mechanical equipment is now installed. Beginning
at the ground and working up, the wall and window
units are slipped into their grooves between mull­
ions and made fast with bolts. It is possible to erect
the interior partitions before the exterior wall and
it may develop later that it is best. However, they
are not too large to be taken through the doors or
windows, and this is the intention at present.

The base for the partitions is first secured to the
floor, by driving cold pins into the steel floor plate. The partition slabs are then slipped up into their ceiling grooves and dropped down into the groove in the top of the base.

The Merchandising Organization. Although these houses are not contemplated to serve the lower income group at the present time, it is possible that the economies subsequent to industrial mass production may lower the cost substantially and make them available to a much larger market than is now contemplated. In effect this means the establishment of a new industry and implies a merchandising plan that should be flexible enough to be susceptible to modification in the case of unforeseen commercial conditions. The organization involves the establishment of a parent company which in effect will be a research and directing organization. It will develop and improve house plans and specifications, details of construction and equipment. It will conduct a constant research on new materials and methods of fabrication and erection. It will organize market surveys and control the dissemination of authentic information to the public. In addition it will control all patent rights and establish all contracts with industrial concerns for manufacture of the houses.

It is possible that at some future date the parent company will manufacture the houses as well as control their plan and design. The advantage of the plan outlined, however, utilizes most efficiently already existing machinery and obviates the necessity of a large initial capitalization of the parent company. In addition it assures the lowest price level to the consumer, as it is possible to change and improve the plans and specifications, details of construction and equipment. It will conduct a constant research on new materials and methods of fabrication and erection. It will organize market surveys and control the dissemination of authentic information to the public. In addition it will control all patent rights and establish all contracts with industrial concerns for manufacture of the houses.

The parent company will authorize the establishment of distributors throughout the country who will purchase the houses from the parent company and resell them to the buyers. This organization will contract with the parent company for a definite number of houses per year, delivery to be made when needed. Should the distributor require more than the number originally ordered he establishes a credit with the parent company, as the price of the houses is necessarily controlled by the quantity of their manufacture. If he is unable to sell his quota, he is charged an extra to cover the cost of warehousing, in the case of houses originally ordered, or to adjust the manufacturer's price with the parent company for the added unit cost necessary for a smaller quantity of units.

The distributor will maintain his own erection crew who will be especially trained for the erection of these houses in the manufacturing plant where every tenth house will be assembled and knocked down before it is shipped. The distributor will maintain also a service organization for the replacement of parts and the adjustment of any misunderstandings between himself and the home owner.

The price of the house will be divided between the distributor and financing company, the manufacturer and the parent company. The distributor will receive 17 per cent, the manufacturer 80 per cent and the parent company the remaining 3 per cent. The houses will be sold by the distributor under the following plan:

The prospective buyer must have title to the property on which the house is to be erected. The property should be clear of all incumbrances but at the option of the financing company and if the mortgage on the property is a small one, the distributor may accept a down payment of 20 per cent on the house purchased, clear up the existing incumbrance on the property and execute a blanket mortgage on the house and lot combined, which will be paid in equal monthly payments over a period of 15 years with interest payable at the same time at the rate of 5 per cent. Mortgage paper of this kind is an attractive investment and should find a ready market at rediscount.

The prospective buyer, however, is not obligated to make use of the financing company which collaborates with the distributor. He may make any other arrangements he sees fit so long as the distributor is paid in full for the house. The distributor deducts his percentage and turns in the money to the parent company who pays the manufacturer.

The houses are sold to the consumer under a guarantee for five years against defective materials and workmanship during which period the buyer may receive repair and replacement services without charge. Any defective parts will be furnished the distributor through the parent company.

Editor's Note: Any house as unusual in architectural design and construction as those designed by Bowman Brothers deserves a more extended explanation than can reasonably be included in one article. The industrial approach to the solution of the technological problem of housing is a comparatively new one and implies an extensive research into the physical properties of the materials employed and a close analysis of each item of cost. In a forthcoming issue of THE ARCHITECTURAL FORUM, Irving H. Bowman continues his explanation of these factory-made houses. The article will deal with the factors of prefabrication and the field assembly of parts, with particular emphasis on comparative costs and specifications. It will contain tabulations and cost analyses of operations in the fabrication and erection of the houses, including excavating, the structural floor systems, the wall construction, the window system and the insulation and facing materials.
A "HOUSING PROJECT" of improvised shelter built by and for the unemployed on a vacant lot in New York, at 12th Avenue and 40th Street, known to its tenants and the police as "Shanty Town." At the left the "mayor" rings his bell announcing the communal meal. Industrialized housing to produce large-scale, planned communities may contribute to the solution of the problems of both unemployment and housing.
WHAT MAKES HOUSING RENTAL?

EUGENE H. KLABER

The rental that is paid for the use of premises is the result of a number of factors. The cost of land, the cost of the building, including its component factors of material and labor, the financing and carrying charges during the construction, are the elements which determine the total capital cost of a building. Given the capital structure, the rental charged must provide for the following: vacancies, operating expenses, taxes, interest on mortgages, insurance, depreciation, and, where a corporation is involved, federal income tax. What is left over is the return on the equity.

Long experience with a variety of projects has enabled competent bankers, architects and real estate men to estimate with a fair degree of accuracy the effect of these various elements upon the ultimate rental. Their method, however, is entirely empirical, and as no two projects present exactly the same conditions, there is no definite assurance that they will apply in a given case. For instance, if we assume that approximately ten per cent of the capital cost is financing cost and carrying charges during construction, there will always remain the question of the applicability of the assumption to a given project.

It has occurred to the writer that it might be of interest to evolve a more mathematical approach to the question. Experience with a large housing project and a knowledge of the cost, operating expenses and rental charged, has raised the questions: What would have been the rental under other circumstances? With the building cost determined, what would have been the effect of varying the financial structure? On the other hand, if elements of the land and building cost had been reduced, how would the rentals have been affected? How would the rental saved by reduced capital cost compare with what might be saved by reduced rate of interest on money?

These questions are very pertinent at a moment when, in the search for some solution of the housing problem, all sorts of remedies are being suggested. There are many who are searching for a solution through the adoption of new materials and simplified methods. Others feel that the cost of land is the predominant factor. Others, again, are quite sure that a reduction in the wages of labor would go a long way toward solving the problem, and some look to a solution through obtaining cheaper money. Probably all of these elements will have to play a part in the picture, but, relatively, what is their importance in accomplishing our end?

It is possible to investigate these elements mathematically by treating one element as a variable and keeping all other elements constant. Repeating this process for each element in the picture will give results that are significant, and may pretend to be somewhat more authoritative than those obtained by the usual empirical process.

In this investigation the elements of capital structure, interest, rentals and operating cost, taxes, etc., were all known. One problem was to evolve formula of conversion of cost elements into rental. Thus, it was necessary to determine how much rental was represented by every dollar of capital cost and how much by each dollar of operating expense, interest, etc. It is not proposed to enter into the somewhat elaborate calculations that were necessary to obtain the results. Suffice it to say that, although there were certain elements in which judgment had to be used to determine minor factors, the method is, by and large, mathematical and the margin of possible error due to problematical factors is small.

The results of this study are shown in Figures 1 and 2. Figure 1 represents an investigation of the method of financing. The project in question is shown as Case No. 2, and inasmuch as no commissions were charged on the mortgage or carrying charges on the land during construction, it has been designated as semi-philanthropic financing. The rental of $17.55 shown is not the actual rental being charged.
charged, but the rental which it would be necessary to charge in order to earn 6 per cent on the equity. In all four cases the assumption has been made that the equity earns 6 per cent.

It will be noted that the cost of the land, building and overhead is constant in all four cases. The varying factors are the rate of interest on the money, commissions charged on the loan and the financing and carrying charges. In the graph, Case No. 3 has been called conservative financing, inasmuch as the first mortgage is only 50 per cent and the equity is 30 per cent. Case No. 4 is a customary method of financing. No examples of so-called "shoestring" finance are shown.

These three cases represent instances sufficiently frequent in America to be called typical. All may be said to be within the range of current possibilities. It will be noted that the spread in rental between the lowest and highest is only $1.88 per room per month. If, however, we step outside of the range of what is currently possible and consider what the effect on rental of a subsidized financing would be, we get a picture analogous to Case No. 1. In this it has been presumed that there is no tax on the building, and no commission on the mortgages. The capital structure is set up on the basis of a housing project in Berlin, in which a 37.2 per cent first mortgage was made by a savings bank. An additional 13.3 per cent constituted the second mortgage, the money being loaned by the city of Berlin at 2 per cent interest and 2 per cent annual amortization. An additional 40 per cent of the total capital was lent by the government at 1 per cent without amortization for five years.

This loan was derived from funds collected by the taxation of rentals. The remaining 9.5 per cent represents the equity. In determining the rental in Berlin, a 5 per cent return is allowed the owner of the equity if it is a public utility corporation. If he is a private individual, he is allowed 7 per cent. For purposes of comparison with the other cases the return on the equity has been figured at 6 per cent.

Figure 1 makes evident the importance of the rate of interest and the method of financing. The attempt has been made merely to derive a method by which housing projects can be studied with perhaps a closer approximation to the truth than has been possible in the past.
that in Case No. 1 the rent is $12.96 per room per month, whereas in Case No. 4 (the customary method) it is $19.47 per room per month, or almost exactly 50 per cent more.

There are several reasons for this. In Cases 1 and 4, the equity is comparatively small, but in the former, only 35 per cent of the gross rental has to be devoted to the payment of interest on mortgages and equity, whereas in the latter it amounts to 45 per cent. Comparing Cases 1 and 2, we note that the financing and carrying charges in No. 1 are higher than in No. 2, as well as the interest on mortgages. But this is overbalanced by the very large equity in No. 2, on which 6 per cent has to be earned, the interest demands on the gross rental amounting to 41 per cent as compared with 35 per cent in the subsidized financing.

In Case No. 4 the tenant occupying a four-room apartment would have to pay $934.56 annual rental as compared with $622.08 in Case No. 1. Note: This is for exactly similar quarters, produced with the same contract cost, the same building and general overhead; operating costs, taxes and insurance being exactly the same, as well as the allowance for vacancies. It is obvious, however, that with the lower rental, Case No. 1 would have a much smaller percentage of vacancies than Case No. 4. The buildings being identical in both cases, the question at once arises, whether it is equitable to build dwellings similar to those produced by private enterprise which, in this instance, by virtue of government subsidies, can offer rentals one-third less. As long as our economic system remains one which encourages private initiative wherever possible, such an underselling is entirely unfair. We know that proper housing is an essential need of mankind, and that under present conditions it cannot be furnished by private initiative to rent within the spending capacity of a very large share of the population, and that, in some way, government must recognize this fact and lend its assistance.

How, then, is it to be done? The answer is obvious: Government assistance must be devoted to the financing of housing that is unlike that produced by private builders. The latter, in their competitive struggle, are obliged to include in their buildings many elements of luxury and service that could well be dispensed with in our endeavor to produce housing at low rentals. In a word, subsidized housing must be of such simplicity that it furnishes only the elemental needs of shelter and sanitation, at rentals sufficiently low that there is no longer any question of competition. An entirely different demand will be met, just as the market for the lowest priced cars is different from that of the more expensive types.

To accomplish this we must attack all the elements that go to make up the total rental. Land cost must be low, service and luxury cut down to a minimum, labor costs as inexpensive as possible, and interest on money as little as we can make it. The possibilities of such reductions in cost are indicated in Figure 2. This shows varying elements of cost and interest on money as compared with the known project. In each case the point of departure is a rental of $17.55 per room per month, which is the necessary rent to allow 6 per cent on the equity.

Under the head of land cost we show four examples: $1.87 per sq. ft. is the actual cost. If the land were $1 per sq. ft. or 50 cents per sq. ft., the resultant rental would be, respectively, $16.91 per room per month and $16.54 per room per month. If, however, an increased price had been paid, a $4 land value would result in an increase in rental of only $1.55 per room per month.

The second investigation shows the reduction in rental that would occur if the elaborate heating system in the existing project were replaced by a less expensive system in which the tenant furnished his own heat. This would result in a capital saving of $150,000 and a reduction in fuel and maintenance cost of $31,000 per annum. For purposes of comparison there has been added back 60 cents per room per month for the fuel that the tenant would have to buy. This is done because our interest is what the tenant has to pay for his shelter and fuel, whether he pays it all to the landlord or whether part is paid to a public service company. A reduction in the capital cost of 7½ per cent and in the operating cost of 32 per cent reduces the rental per room $1.49 per month.

In the known project there is approximately $180,000 of the capital cost which represents elements of luxury which could well be omitted in a simplified project. Had these been omitted there would be a saving of only 90 cents per room per month, if the same return is to be made on the equity.

The fourth variant shown is the cost of the job labor. It has been assumed that approximately 50 per cent of the building cost, without overhead, is job labor. There are many who maintain that a reduction in the wages of building labor would immediately open up building operations. On the project studied, mechanics in the building trades earned, by and large, $1.62⅔ an hour. We have considered what would happen, first, had the wages been 20 per cent lower, and secondly, had a flat rate of $1 per hour prevailed, or a reduction of 38 per cent. It is interesting to note that the 38 per cent reduction would have resulted in a rent saving of $1.86.

Our final study illustrates the effect of reduced interest on money. Starting with a return of 6 per cent on the equity and 5½ per cent on the mortgage, each is reduced successively by 1 per cent until in the fourth example the equity has a return of 3 per cent and the mortgage 2½ per cent. The drop in rentals is very marked. Thus, by a reduction of 3
per cent in the interest rate we obtain a reduction in the rental of 24.2 per cent. Comparing these various results, we find that reducing the rate of interest on equity and mortgage 1 per cent $t$ has about the same influence in reducing the rental as:

(a) Acquiring the land for nothing; (b) omitting the heating service and reducing the cost of the heating system; (c) omitting 14½ per cent of the building cost, or (d) reducing wages of job labor by one-third.

This demonstrates conclusively the enormous importance in future housing, of obtaining money at low rates of interest. It is by no means the whole story but more than any other factor it will help us toward a possible solution.

This study has taken an existing project, and the variants shown involved no changes in the actual layout. One of the elements that has not been shown is the amount of savings that might be effected by a 1 per cent in the annual cost of this item.

More economical planning. This has not been done because it would be almost impossible to make anything like an accurate monetary comparison. Those who have studied this problem know that savings can be made by economy in the layout. This does not mean skimping the size of rooms by square inches, although they must conform to reasonable minima. The study of such economies must rather center around the simplification of the layout and the increase in the number of elements that are repetitive.

Job experience shows that where, for instance, bathrooms are all exactly the same in fixtures and layout, the workman becomes rapidly trained in the process of installing fixtures, and the curve of labor cost per unit drops quickly as the gangs get into the swing of the work. The same is true of laying brickwork, setting concrete forms and many other divisions of the work. Repetitive units in planning also point to the possibility of developing sectional construction which can be fabricated and sent to the job to be installed in place, with the elimination of much of the usual fitting and cutting.

The equipment units illustrated on these three sheets of data and details are particularly adaptable to the small house or apartment. No effort has been made to show a complete size range of the units illustrated or the more commonly used pieces of standard equipment. The information is useful in providing plan space for these items of equipment.
Almost every item illustrated on this page is in general use in small homes and apartments and space for their storage should be included as an important part of the plan. The sizes marked illustrate the average of several types. They are reproduced at a scale of $\frac{3}{4}$ in. to the foot, making it easy to plan for them on $\frac{3}{4}$ or $\frac{5}{8}$ in. scale working drawings.
PRODUCTS AND PRACTICE

The Forum staff seeks out new materials and methods which merit the attention of architects. Here each month is presented concise news covering purpose, advantages, and other pertinent facts about recent developments.

FACTORY FABRICATED FLOOR UNITS

HIGH strength, increased speed in erection time, and reduction of dead load are three factors incorporated in a new type of steel floor construction. The units, 24 in. wide, and up to 12 ft. 5 in. long, are constructed of two pre-formed steel sheets welded together to form four keystone-shaped cells. In erection, the sections are laid across the structural beams, and are welded, bolted or clipped to the supporting members.

For the two types of flooring shown in diagram, the physical properties are as follows:

Concrete fill is applied directly to the surface of the floor, and any type of floor covering may, of course, be used as a finish. Ceilings can be suspended from the underside of the flooring as can steam or water pipes. Since the keystone-shaped ducts are (Continued on adv. page 14)
Again BYERS Pipe specified on WROUGHT IRON service record

The Old Board of Trade, erected 1882, equipped throughout with wrought iron.

47-YEAR service record in old Board of Trade puts BYERS Pipe in new structure

The Old Home of the Chicago Board of Trade offers this amazing example of wrought iron’s sure economy and dependability.

When the old building was erected in 1882-83, it was equipped throughout with wrought iron piping. Except for building alterations, no replacement of the original wrought iron pipe was necessary up to the time the building was demolished in 1929. In these later years, when the prospective life of the building was short, a less durable metal was used in making alterations and, in some instances, this failed before the building was razed. And this is the result of so-called “non-corrosive” lake water.

So convincing was this service record that in the new Board of Trade Building over 230 tons of Byers Genuine Wrought Iron Pipe was used. No surer guide to proper piping material could have been found!

Let “Pipe Prescription” Aid You

Byers “Pipe Prescription” is an accurate, scientific way of determining the right pipe material for the right job. Let it guide you and your clients in pipe selection. Our engineers are at your call. A. M. Byers Company, Pittsburgh, Pa. Established, 1864.

spaced at 6-inch intervals when in place and communicate directly with the corresponding ducts of the adjacent units, the floor may be used, not only as a load-carrying member, but also as a multiple floor duct system for concealment of plumbing, wiring, and other service lines. This type of floor system is particularly advantageous in permitting flexibility in electrical wiring. Changes in outlets may be effected more quickly and with less cost than heretofore.

Actual savings in construction costs will result from the elimination of ducts, reduction of field labor, elimination of temporary planking and masonry forms, and by the saving in time effected by allowing electrical and other trades to follow with their work as soon as the floor is in place.

This floor system was developed by the Mellon Institute of Industrial Research in conjunction with the H. H. Robertson Co. of Pittsburgh. It is known as the Keystone-Robertson Steel Floor, and further data may be obtained from either of the above organizations.

DOUBLE PANE INSULATION GLASS

CONSISTING of two layers of glass with a sealed air space between them, a new window glass has been developed which offers heat insulation, sound insulation, and resistance to frost and moisture. Since the new double-glass window saves from 40 to 63 per cent of the heat lost through windows, its importance in fuel economy and in general air conditioning is obvious. Already available for use in windows, doors, and partitions, it is likely to play an even more significant part in the glass-walled house of the near or distant future.

The dehydrated air between the panes, sealed by special bonding material to make it airtight, watertight, and dustproof, offers the same resistance to sound and heat transmission that dead air space does in any other insulating material. Although the product is furnished standard with 3/8 in. or 3/4 in. air space, it can be furnished with 3/16 in. or 5/8 in. space between. It can

TRUSCON STEELDECK ROOFS

Light Weight, Insulated Roofdecks

Firesafety and permanent, with simplicity of laying, economy of welding or clipping in place, ease of applying acoustical correction, freedom from expansion, contraction and condensation troubles and free from excessive cost of maintenance. Both Ferrobord and Ferrodeck are applicable to varying purlin spacings. Truscon Steeldecks have been specified for hundreds of diversified buildings and have proved thoroughly satisfactory installations.

TRUSCON STEEL COMPANY, YOUNGSTOWN, OHIO
Engineering and Sales Offices in Principal Cities
Crane materials make it *economical* to have *good taste*

The sound and original decorative effects to which Crane materials lend themselves more completely than do any others is due to the liaison Crane Co. has always maintained with architects. Otherwise Crane Co. could never have foreshadowed the trend towards harmonious interiors by developing the first ensemble groups or designing other fixtures so architecturally functional as those used in the illustration. For Crane materials make possible bathrooms where the quality of unity is as real and as pleasing as in a well ordered living room.

This is one phase of Crane service to architects. The other, and equally important one, is its constant widening of the architect’s influence in bathroom planning by bringing such materials within the range of every builder’s budget. Today, for example, such fixtures as these can be purchased and installed for actually less than drab tastelessness cost a few months ago.

ROME CONVECTORS

Notable installations where Rome Convecators were chosen:

- Kings County Hospital, Brooklyn
- Federal Reserve Bank, Pittsburgh
- Adler Planetarium, Chicago
- Whitney Gym, Yale University
- Shaare Emeth Temple, St. Louis

The preference for Rome Convecators is growing rapidly... because of the enviable reputation acquired from thousands of successful installations.

**BUILT UP TO A STANDARD NOT DOWN TO A PRICE**

Rome throws the whole weight of its resources and manufacturing facilities into quality. Not only has Rome consistently refused to sacrifice quality for price... but is actually building Convecators to an even higher standard of quality.

**Standard Types and Sizes of Rome Convecators**

Rome has standardized its ROCOP Convecators as to types, sizes (of which there are 21) and methods of installation. This standardization simplifies estimating and installation, eliminates errors and delays, and is sufficiently flexible to meet all requirements.

ROBRAS Convecators are available in a wider variety of types and sizes, including those for out-of-the-ordinary requirements. Rome Convecators are assurance of permanent satisfaction. They may be specified with confidence as to their performance and endurance. For further information send for ROCOP and ROBRAS Bulletins.

**PRODUCTS AND PRACTICE**

(Continued from adv. page 14)

be supplied in any type of flat glass and in any shape or size up to 48 in. x 48 in. Cut to specified dimensions by the distributors, the product cannot be cut on the job, nor is it at the present time carried in stock sizes.

Manufactured under the trade name "Thermopane," information may be obtained from Charles D. Haven, Milwaukee, Wis., or from J. Flint Foster, distributor, 205 W. Wacker Drive, Chicago.

**STAINLESS STEEL SINK**

STAINLESS steel, already being widely used in restaurant and kitchen equipment because of its easy maintenance and resistance to fruit juices and other acids is now being employed for kitchen sinks. Made in four standard lengths, 4 ft., 5 ft., 6 ft. and 7 ft., with double or single drainboards, the new units are entirely seamless. The underside is treated with a sound deadening material. Features of the design are: 8 in. basin with removable stopper-strainer, full length ledge and 8 in. splashboard at back, movable mixer-faucet equipped with spray, 54 in. flexible hose for rinsing dishes, and quick compression faucets with swivel-valve seats. A further advantage of this new sink is that the material of which it is made is less bulky than almost all other sinks, and therefore it occupies less work area. Forty different models are manufactured by the Bossert Company, Utica, N. Y., who have designated their product as the Hydrocrat.

**NOISELESS RIVET-BOLT**

REDUCTION of noise in steel erection through the elimination of the rivet gun has been accomplished by use of a new rivet-bolt for joining structural steel members. The rivet-bolt has a ribbed shank, slightly larger in diameter than the punched hole, which bites into the metal of the plates, and a self-locking screw thread which produces a positive locking of nut and bolt. Holding quality equal to that of a rivet is obtained by the combination of these features.

In using the rivet-bolt, not more than two men, instead of the usual four in the rivet gang, are required. The bolt is driven into the punched hole with a hand hammer, and the nut is spun around by hand until it seats itself against the structural plate, after which it is... (Continued on adv. page 18)

tightened by a wrench. The self-locking thread holds it secure.
Manufactured by the Dardelet Threadlock Corporation, 120 Broadway, New York, the new rivet-bolt has recently been subjected to structural tests at Columbia University.

ULTRA-VIOLET AND ILLUMINATIVE LIGHTING FIXTURES

Combined in one fixture the advantages of ultra-violet and illuminative light are now obtainable for all types of commercial buildings. These dual-purpose fixtures operate on two circuits, one for the bulbs used for illumination, and one for the single bulb which radiates ultra-violet.

The transformer required for the ultra-violet bulb is concealed in the fixture itself, or it may be installed in the ceiling covered by a plate. Light from the ultra-violet bulb may be either direct or indirect. In the former it is necessary to use the circuit for only short periods of time, whereas in the latter, the bulb may be permitted to burn all day. The accompanying photograph shows the interior construction of the direct- or semi-indirect type, with the transformer embodied in a canopy.

Detailed information on these Duo-Purpose lighting fixtures may be obtained from the Miller Company, Meriden, Conn.

OIL BURNING FURNACE

Designed to utilize the heavy and less costly domestic fuel oils, a new type of oil burning furnace has been developed by the General Electric Company, Schenectady, N. Y. This is the first step of the company in its program of manufacturing all the units of air conditioning equipment.
RECENTLY, Lowell General Hospital, Lowell, Mass., increased its capacity from 75 beds up to 150. Which sent exactly twice as much work streaming into its already-crowded laundry department. The hospital’s architects, knowing of the changes in laundry volume, sent out a call for the Specialists of The American Laundry Machinery Company. Together they checked, weighed, measured, estimated — then agreed on a thorough renovation, with modern, motor-driven “American” equipment.

Now Lowell General Hospital’s laundry standards are higher than ever. Laundry operating costs are low. And the remodeled department, in the same floor space, handles easily twice as much work! When your specifications reach into the laundry field, you can save hours and dollars by conferring with “American” Specialists. Their service will not obligate you in any way.

Two views of Lowell Hospital’s laundry department, modernized with the aid of “American” Specialists. Notice the novel metal Cascade Washers, Under-driven Extractors and Flat Work Ironing Unit — also the special-shape, quick-action American Eagles, ideal presses for hospital-laundry work.

NOTICES AND EVENTS

WILLIAM SYDNEY WAGNER
1883-1932

William Sydney Wagner of New York, member of the firm of Bottomley, Wagner & White, died May 27. Mr. Wagner, whose professional career dated from his winning of the Prix de Paris in 1907, specialized in hotel work, having designed the Statler hotels in Buffalo, Boston, St. Louis, Detroit, and Cleveland. Two of his most prominent buildings in New York were the Hotel Roosevelt and the recently completed River House. Mr. Wagner was a graduate of Cooper Union, Beaux Arts Institute of Design, and L'Ecole des Beaux Arts. He was at one time associated with George B. Post & Sons.

NEW YORK CHAPTER OFFICERS

Charles Higgins has been elected president of the New York Chapter of the American Institute of Architects for 1932-33, succeeding Stephen F. Voorhees. Other officers elected were Dwight James Baum, vice president, Eric Kebbon, secretary, Frederick Mathesius, Jr., treasurer, and Christopher LaFarge, recorder.

MRS. AYMAR EMBURY II
1890-1932

Mrs. Aymar Embury II, known in her professional capacity as a landscape gardener as Ruth Dean, died May 26 at her home in New York. Mrs. Embury was probably best known for the landscaping of the Detroit homes of Mrs. Howard Bonbright, Hiram Walker, and Ledyard Mitchell, for which she received the Architectural League of New York's Gold Medal of Honor in Landscape Gardening. Mrs. Embury was a graduate of the University of Chicago.

CONRAD ARTHUR THOMAS
1858-1932

Conrad Arthur Thomas, mural painter, died June 8 at his home in North Pelham, N. Y. Among Mr. Thomas's best known murals are those in the St. Louis City Hall, the Courthouse at Auburn, Ind., the Hotel Sinton in Cincinnati, the Courthouse at South Bend, Ind., the Seelbach Hotel in Louisville, Ky., and the Cathedral of Saints Peter and Paul in Philadelphia.

EARL HARVEY LYALL
1877-1932

Earl Harvey Lyall, Federal architect, died June 6 at Selfridge Field, Mich.

J. G. VAN HORNE
1853-1932

J. G. Van Horne, consulting engineer for many suburban developments in the vicinity of New York, died June 6 in that city. Mr. Van Horne was a graduate of New York University, and a member of the American Society of Civil Engineers.

McKIM FELLOWSHIP

For his design of a skyscraper to house all the activities of Columbia University, Howard Bahr of Sayville, Long Island, has been awarded the $2,500 Charles Follen McKim Traveling Fellowship. Second prize of $800 was awarded to James Sasso of Brooklyn, N. Y., and third prize of $500 to Joseph De Marco of Farmingdale, Long Island. The jury of award was composed of Dean E. V. Meeks, Arthur Loomis Harmon, Harvey Wiley Corbett, Ely Jacques Kahn, and William Adams Delano.

J. E. R. CARPENTER

One of New York's most important skyscrapers architects, J. Edwin R. Carpenter, died suddenly in his office June 11. Mr. Carpenter was the architect for the Lincoln Building, and for many large apartment houses in the city. In 1916 he was awarded the Gold Medal of Honor for a 12-story apartment house at 907 Fifth Avenue, and in 1928 he was similarly honored for an apartment house at 819 Park Avenue.

Mr. Carpenter was born in Columbia, Tenn., and was graduated from the Massachusetts Institute of Technology in 1887. He studied at L'Ecole des Beaux Arts, and upon his return, entered practice in Norfolk, Va., before coming to New York.

LENIN MONUMENT COMPETITION

An international competition for the design of a monument to Lenin has been announced by the U. S. S. R. Six prizes are to be awarded, ranging from 10,000 rubles to 2,000 rubles. The closing date for entries is September 15, 1932. Information may be obtained from the Amtorg Trading Corporation, New York City.

ILLUMINATION DESIGN COMPETITION

E. Young, student of Atelier Adams-Nelson in Chicago, was awarded first prize of $750 in a competition among students for designing illumination for "a great hall at the Electrical Building, Chicago World's Fair." A. E. Alexander of Catholic University won second prize of $250, and H. L. Kampoeufner, Sioux City, third prize of $150.

(Other Notices and Events will be found on adv. page 22)
REPUTATION also depends upon the care exercised in the MAINTENANCE of your building.

You can turn over the keys of a new building but your reputation will be locked up in its future for many years to come. You may have specified standard protective systems but unless they are carefully MAINTAINED—always—their failure in an emergency will have an unfavorable reaction.

Watchmen's systems... manual and automatic fire alarms... burglar alarms... sprinkler systems, when supervised, minute by minute, from an A.D.T. Central Station, receive PERPETUAL CARE—assurance that they are constantly in perfect operating condition. Nothing can happen, day or night, to interfere with the proper functioning of protective devices without A.D.T. taking immediate action!

It will profit you to investigate the Central Station protection facilities of A.D.T. They are available in almost every large city from coast to coast.
NOTICES AND EVENTS

(Continued from adv. page 20)

City, Iowa, won third prize of $150. Fourth and fifth prizes of $50 each were awarded to F. O. Dester, University of Illinois, and H. Tonsager, Armour Institute of Technology, respectively. The competition was conducted by the Beaux Arts Institute of Design, the American Institute of Architects, and the Illuminating Engineering Society. Foster Gunnison was chairman of the committee.

HONORED BY N. Y. U.

N. Phelps Stokes, architect, and Thomas Adams, architect and regional planner, were recipients of honorary degrees at the commencement ceremonies of New York University. The degree of Doctor of Letters was conferred upon Mr. Phelps Stokes, chiefly because of his book, "The Iconography of Manhattan Island," and the degree of Doctor of Science upon Mr. Adams for his contributions as director of the Regional Survey of New York and Its Environments.

BAYONNE BRIDGE WINS PRIZE

Because "beauty and symmetry had been achieved 'at the price of honesty'"' in the George Washington Bridge over the Hudson, the Bayonne Bridge over the Kill van Kull won the prize offered by the American Institute of Steel Construction for the most beautiful bridge costing more than $1,000,000 opened during 1931. The Washington bridge placed second. Othar Hermann Ammann, chief engineer of the Port of New York Authority, designed both bridges.

The prize for bridges costing between $250,000 and $1,000,000 was given to the Waldo-Hancock Suspension Bridge over the Penobscot River at Bucksport, Maine. It was designed by Robinson & Steinman of New York. In the class for bridges costing less than $250,000, the award went to the West Stewartstown Bridge over the Connecticut River at West Stewartstown, N. H. The design for this bridge was created by the New Hampshire State Highway Department.

ERRATUM

IN THE reproduction of the Art Gallery at Mystic, Connecticut, on pp. 563-564 of the June issue, the credit line should have read, Jackson, Robertson & Adams, Architects; George Fraser, Associated. We regret having omitted Mr. Fraser's name.

FRANK PERNA
1884-1932

Frank Perna, architect and publisher, of Hoboken, N. J., died suddenly June 14. Mr. Perna received his professional training at the University of Naples, from which he was graduated just prior to his coming to this country 27 years ago. He was the architect for many small buildings in New Jersey, and was president of the Iventus Publishing Company and of the Circolo Italiano.

LITCHFIELD HEADS ART GROUP

Electus D. Litchfield, prominent New York architect, has been elected president of the Municipal Art Society of that city. The society is, in the words of its new president, "the only official body representing the citizen in furthering the beauty of the city and its artistic possessions."

"HOUSE BEAUTIFUL" COMPETITION

The annual competition sponsored by House Beautiful magazine for the best six-to-twelve-room house closes this year on October 17. In addition to the prizes awarded in that class, there is a special prize of $300 for the best house of from five to seven rooms, costing less than $10,000, built in any section of the country. The regular awards consist of three prizes, $500, $300, and $200 for the best houses built East of the Mississippi, in one class, and West of the Mississippi, in the other. Further information about entries may be obtained from the magazine, 8 Arlington Street, Boston.

DEDICATION OF BRITISH BUILDING IN ROCKEFELLER CENTER

The cornerstone for the British Empire Building, one of the foreign units planned for Rockefeller Center, is to be laid July 2. Lord Southborough, who is prominent in the directorate of the company backing the British unit, and H. H. Stevens, Canadian Minister of Trade and Commerce, will speak.

The Bayonne Bridge over the Kill van Kull, Othar Hermann Ammann, chief engineer
CHARACTER suitable to the intended role, and modifications that are nicely governed with particular results in view—such are the advantages provided in the series of USS STAINLESS and Heat Resisting Steels as a result of long research and unsparing effort.

Name your field—industrial, chemical, refining, manufacturing, food handling, architectural, domestic—and your specific use, and the technical staff working with these special alloys will recommend a grade appropriate in cost and adapted to your need. New problems will be considered carefully in order that discriminating advice may be given.

DUAL-AUTOMATIC

WITH HERMETICALLY-SEALD
MECHANISM AND FORCE
DRAFT COOLING COMBINE
ONLY IN THE WESTINGHOUSE
REFRIGERATOR

ASSURES THE DEPENDABILITY
DURABILITY AND ECONOMY
APARTMENT OWNERS HAVE
RIGHT TO EXPECT

Apartment owners interested in realizing the most satisfactory return from their investment in electric refrigeration will do well to investigate the important list of reasons for which these features are combined in the Westinghouse Dual-automatic Refrigerator.

One feature alone—the exclusive "Spend Disc" thermostat control—eliminates one of the greatest causes of adjustment in refrigeration. It keeps the Westinghouse Refrigerator automatic through emergencies of all kinds... assures troublefree uninterrupted performance. 'Because of the splendid service which these refrigerators have given, it has not been necessary, up to this time, that I call you in a single instance on a repair or trouble call,' writes T. J. Murray who installed sixteen refrigerators a year ago.

This fact is significant... Dual-automatic performance is one of the most important reasons for the minimum upkeep expense of the Westinghouse Refrigerator. The hermetically-sealed mechanism is another. All mechanism is sealed in a permanent supply of oil... sealed against the ravages of time, corrosion and wear... protected against tampering. And forced-draft cooling, added to speed the natural cooling action of room air, contributes to the efficiency and economy of operation.

Furthermore—new allsteel construction gives the Westinghouse Refrigerator rugged lifetime durability. And with other important improvements assures the dependability and durability expected by tenants and hope for by owners. 'It is gratifying to have all my tenants express their complete satisfaction with your refrigerators,' writes R. O'Brien.

From the standpoint of tenant satisfaction to that of investment return, the Westinghouse Dual-automatic Refrigerator meets the requirements of profitable apartment refrigeration. It will pay you to investigate thoroughly before investing another penny.

Let us give you complete details about interesting cost figures and data. Fill out and mail the coupon for convenience.
Where

DURIRON Drain Pipe

should be specified . . .

Corrosive wastes are enemies of a great many well-designed buildings. There is one way to overcome the costly tear-ups and replacement expense they can cause, and that is to use Duriron Acid-proof Drain-pipe.

Drainage from laboratories, for instance, is powerless against Duriron, because Duriron is acid-proof all the way through its structure, inside and outside. It does not depend on coating, lining or glaze for corrosion-resistance. Another advantage is its metallic strength.

Every building with a laboratory should be protected by Duriron Acid-proof Drain-pipe . . . schools, colleges, universities . . . hospitals, medical buildings, industrial plants.

Wherever else waste lines must handle corrosives, Duriron has a place . . . photo-engraving and electro-plating plants . . . storage battery rooms . . . soda fountain and commercial kitchen drainage subject to attacks from fruit and food acids and washing compounds.

Duriron Pipe is installed like extra heavy cast iron soil pipe and outlasts the building in which it is placed. See Sweet's Catalogues for further information or write us.

THE DURIRON CO., INC., 446 N. Findlay St., Dayton, Ohio
ALTHOUGH the President's Conference on Home Building and Home Ownership fell understandably short of finding all the answers to all the questions of low cost housing, the final results of the many sessions held last fall in Washington are likely to exceed the expectations of most of us. For one thing, the sorry state of the nation's housing has become a significant issue. Not only social workers and architects, but bankers, politicians, and the general public have discovered that good housing for the poor is fully as important a national problem as Prohibition.

Those with a professional or business interest in residence construction were, no doubt, disappointed by the immediate outcome of the Conference. It seemed, at the time, that there had been nothing but talk. An entirely different impression will be obtained, however, from study of three volumes of reports that have recently been issued in permanent bindings. Facts that received no publicity, experiences that were forgotten as soon as they had been related, and concrete proposals that apparently were lost in the mass of less worthy material have been assembled by the Committee to form an extremely valuable manual on housing.

Ten different committee reports are included in these first three volumes. Under the titles, "Planning for Residential Districts," "Home Finance and Taxation," "Slums, Large-Scale Housing and Decentralization," the following subjects are discussed: City Planning and Zoning, Subdivision Layout, Utilities for Houses, The Relation of Size of Lots to Cost of Utilities and Street Improvements, Landscape Planning and Planting, Housing in Unincorporated Areas Adjacent to Cities, in Volume II, Financing Home Ownership, President Hoover's Statement on the Proposed Establishment of Home Loan Discount Banks, Taxation and Housing; in Volume III, Blighted Areas and Slums, Large-Scale Operations, Business and Housing, Industrial Decentralization and Housing.

One of the most thorough studies is that on subdivision layout, which was prepared under the direction of Harland Bartholomew. Costs and methods are outlined with a clarity seldom found in any other discussion of the subject. Another important chapter in the same volume is the one dealing with relation of the size of lots to the cost of utilities. Drawn from the actual experience of regional planners, realtors, and developers from sections, the data to be found here is invaluable.

Equally instructive is the volume on finance and taxation. Never before has such a thorough study been made. The opinion and experience of almost every expert in the country are included in it.

The third volume is chiefly valuable for its chapter on large-scale operations, for which Alfred K. Stern of Chicago and Henry Wright of New York are chiefly responsible. Although much of the material had been published before, it had never been assembled in one volume.

Those who wish to be brought up to date on this vital question should make arrangements to obtain the first three volumes as well as the several volumes which are soon to be released.

PLANNING FOR RESIDENTIAL DISTRICTS; HOME FINANCE AND TAXATION; SLUMS, LARGE-SCALE HOUSING AND DECENTRALIZATION. 3 vols. 248 pp., 292 pp., 264 pp., 6 x 9, cloth, illustrated. President's Conference on Home Building and Home Ownership, Washington, D. C. Price $1.50 each.

A chart and a table taken from the chapter on subdivision layout in Volume I of this noteworthy series...
Marshall Field Estate Building, Chicago.

FRAMEWORK OF BETHLEHEM WIDE-FLANGE STRUCTURAL SHAPES
A NEW MODULATING INDOOR WEATHER CONTROL

The new Fulton Sylphon Automatic Unit Heater Control brings vital improvements to unit heater installations—improvements never before achieved by any commercial method.

By regulating the steam flow as well as the fans, this new Sylphon Regulator produces constant, modulated heat wherever unit heaters are employed.

The automatically-controlled steam valve gently corrects room temperature variations as they occur. Fans do not work in frequent on-and-off cycles, causing alternate hot and cold blasts.

As a result, constant circulation supplies working areas with fresh air, directs evenly-tempered heat down to working levels, instead of permitting it to wastefully at the ceiling. Heavy starting duty on fan motors is greatly reduced. Fuel is saved as heat is conserved.

Investigate this latest refinement in industrial heating. Write for complete data before specifying any unit heater control. Ask for Bulletin NA-540.

COMMERCIAL BUILDING PROMOTION

THIS new volume by Charles H. Lench, architect and lecturer, on the subject of commercial building promotion could have been read three or four years ago with immediate profit. With money available and the need urgent, a method of promotion was the only further requirement. Today, however, the ableness of architectural promoters, notwithstanding his familiarity with promotional methods, is having a difficult time of it.

Mr. Lench's book, therefore, may well serve as a guide to what we hope will be future operations.

He discusses with considerable clarity the architect's altered position in the building industry, altered, that is, from the conception of his position held by the student fresh from the atelier. He deals with the specific science of building economics, and defines the relation between banker, builder, realtor, attorney, and owner, indicating the architect's connections with each in the promotion of a building.

Further than that, Mr. Lench outlines the financial set-ups for various types of operations, apartment houses, hotels, office buildings, loft buildings, garages, warehouses, and suburban housing developments. Although only the fundamentals of promotion are sketched, which would be true of any text on the subject, the book is one that will prove valuable to many in the profession who believe that architectural practice can still run in the groove cut for it years ago.

POLICE JAILS AND VILLAGE LOCKUPS

FEW penologists have had so thorough a grasp on the architectural and construction problems of penal institutions as the late Dr. Hastings H. Hart. This small volume on plans for city police jails and village lockups is, like all his other expressed opinions on the subject of penal institutions, a valuable document. In it are included model plans for a large city police station, a medium sized city police station, a small city police station, and a fireproof lockup for a small village. The text is brief and to the point. The plans are large enough in size to permit careful study. Any office contemplating work of this character should obtain a copy of this book.

LIVABLE, MODERN HOMES HAVE
HANDY TELEPHONES AT HANDY PLACES

In the residence of Mr. T. H. Hinchman, 92, Vendome Road, Village of Gross Pointe Farms, Detroit, Michigan, telephone convenience is provided for by built-in conduit connecting ten telephone outlets, including one in the basement game room. Smith, Hinchman & Grylls, Architects, Detroit.

Comfort and efficiency are two prime requisites of up-to-date homes. Telephone convenience contributes generously to both. Telephones at strategic points in important rooms save steps and minutes, simplify household management.

Architects who want to assure adequate telephone arrangements, plan carefully in advance, specify conduit for telephone wires in walls and floors. Then outlets can be located exactly where they're wanted, to meet individual needs. All wiring is concealed and there is greater freedom from service interruptions.

Trained representatives of the local telephone company will gladly help you choose the type of telephone equipment and installation best adapted to your projects. There is no charge. Call the Business Office and ask for "Architects' and Builders' Service."
don't let your clients contribute to the

$500,000,000

ANNUAL RUST LOSS

A considerable part of the national tribute exacted by CORROSION (Progressive Corrosion Fatigue) is levied on exposed metal of buildings.

Rust takes toll of casement and factory sash — fire escapes, cornice supports and stone anchors — gratings and grilles — fences and gates.

Specify Wrought Iron — the Kind That Highland makes. You'll save money for your clients as long as the structure stands.

A request on your letterhead brings valuable data.

THREE ROOMS BY McINTIRE

ARCHITECTS who delight in the New England House of the Early Nineteenth Century, and particularly in the work of Samuel McIntire, will find this book by Edwin J. Hipkiss an interesting addition to their libraries. Three rooms from "Oak Hill," built in Peabody, Mass., in 1801, that have been reproduced in the Museum of Fine Arts, Boston, form the subject of the book. It contains about seventy-five full sized plates and measured drawings, and each one is an outstanding representative of the architecture of the period. The parlor, the dining room, and the parlor chamber are the rooms selected. In addition, there are splendid photographs of the furniture used in them.

THREE McINTIRE ROOMS FROM PEABODY, MASSACHUSETTS, by Edwin J. Hipkiss. 93 pp., plates and text, 9 1/2 x 12 1/4, cloth. Museum of Fine Arts, Boston.

WITH PEN AND INK

WHY and when to draw in pen and ink, what to draw with, how to begin, how to go on, and representative work of master pen and ink draughtsmen are the five chapters which make up this admirable text by Jasper Salwey, an able artist and instructor. Since he is writing for the beginner, Mr. Salwey is unusually explicit in his suggestions, illustrating each point with suitable drawings. His discourse is carried along far enough to provide stimulation for further activity. Among the men whose work is reproduced as exemplary are E. H. New, F. L. Griggs, Frank Brangwyn, Arthur Ferrier, and Aubrey Beardsley. There are fifteen altogether.

SOUND BUSINESS JUDGMENT DICTATES THE USE OF

TE-PE-CO

ALL-CLAY PLUMBING FIXTURES

Our Guarantee

We make but one grade of ware—the best that can be produced—and sell it at reasonable prices. We sell no seconds or culled ware. Our ware is guaranteed to be equal in quality and durability to any sanitary ware made in the world. The Tepeco trade mark is found on all goods manufactured by us and is your guarantee that you have received that for which you have paid.

INSTALLATIONS such as this, made by the Reading Foundry & Supply Company in the great plants of the Wyomissing Industries near Reading, Pa., indicate clearly the increasing tendency on the part of company executives to look beyond immediate needs when plumbing fixtures are specified.

Building owners and architects know that TE-PE-CO fixtures are designed to provide sanitary facilities for large groups of workers with the utmost degree of satisfaction and economy. They are equally well aware of the fact that the quality and durability for which TE-PE-CO fixtures are famous adds materially to the investment values of all properties in which they are installed.

Great universities, nationally known industrial plants, public buildings, hotels, office buildings and hospitals agree that sound business judgment dictates the use of TE-PE-CO.

REASONS WHY!

"Over-the-Top" Door Equipment offers the most revolutionary improvement in garage door operation since garages came into existence.

- Lifts the doors, up out of the way.
- Easily operated by women and children.
- Applicable to OLD or new doors.
- Quickly installed — no costly fitting.
- Never needs adjustment or servicing.
- Weather - tight — no snow or ice worries.
- For doors varying from 8' to 10' in width and 7' to 12' in height.
- Priced within the reach of every purse.

Architects! Write today for complete information on "Over-the-Top" Door Equipment now available in handy form — suitable for filing.

27 YEARS OF LEADERSHIP

in the design and manufacture of

STAGE EQUIPMENT

for THEATRES and AUDITORIUMS

The stage, whether it is connected with a theatre, an assembly hall or a school, is a control point which requires specialized engineering knowledge in planning.

The architect experienced in theatre construction is very likely to avail himself of the cooperation of the Peter Clark organization, for the foremost theatres and largest auditoriums are using Peter Clark equipment.

The architect, however, who is undertaking his first commission involving stage equipment may not be so cognizant of the reputation and achievement of Peter Clark, and we therefore direct special attention to our staff of competent engineers whose services are at the disposal of any architect.

See Sweet's, C-3005, 1907. Correspondence invited

"Stage Equipment with a Reputation"

540 WEST 30th STREET, NEW YORK, N. Y.
FOR STAIR STRINGERS

SAFETY assurance WITH 3 FOLD ECONOMY

Approximately half the weight of lightest standard rolled channels of equal depth.

J&L LIGHT WEIGHT CHANNELS BOTH 10" & 12"

WHILE light in weight, J & L Light Weight Channels have great strength because they are rolled structural sections. When used as stair stringers there is full assurance of safety, together with a saving in steel and economies in fabrication and installation.

1. LIGHT WEIGHT gives saving in steel, less dead load.

2. FABRICATION requires minimum of time, labor and equipment.

3. INSTALLATION is quickly and easily accomplished.

Sizes: 10-inch, 8.4 lbs. per foot, and 12-inch, 10.6 lbs. per foot.
The 12-inch section is especially adapted to stair construction in schools and in other buildings where a broad tread is required.

ENGINEERING DATA

Architects, engineers and fabricators who have studied the properties of these sections have developed widely diversified uses for them.

You may have a problem which J & L Light Weight Channels would solve.

Write for complete engineering data.

A BREAK-DOWN of COSTS

THE profession-wide habit of reducing all items to dollar and cents value prompts us to present the following financial analysis of The Architectural Forum subscription price.

Eight single issues, @ $1 .......... $8.00
Four reference numbers, @ $3 .. 12.00
Total single copy cost ........ $20.00
Actual subscription price ........ $7.00

The increased price for single copies of Reference Numbers is, in part, based upon the increased editorial content of those issues. In addition, it was necessary for us to establish the $3.00 price as self-protection. Practically every Reference Number is now out of print and we must pay a premium ourselves to obtain these back numbers.

We suggest that any who would like to obtain a complete treatise on the design and construction of one type of building four times a year, as well as eight regular issues of The Architectural Forum should fill out the blank below and mail to

THE ARCHITECTURAL FORUM
220 East 42nd Street, New York City

Please send The Architectural Forum to the name and address below for ( ) years

Name ________________________

Street Address

City and State

The subscription price is $7.00 for one year, $12.00 for two (in the U. S. A.). You may enclose a check or attach your card or letterhead to the blank.
"They Keep a-Running"
WHEREVER THERE'S DAMPNESS

In many installations where more or less dampness and moisture are always present, Century Type SC Squirrel Cage Motors are daily proving their service continuity... The windings are thoroughly insulated and are then saturated with insulating varnish. This preserves the insulation, protects the windings and assures the dependable operation necessary in Pumps, Compressors, Refrigerators and similar installations exposed to moisture and dampness... Furnished with either ring-oil phosphor bronze sleeve bearings or grease-lubricated ball bearings.

Built in standard horse power ratings from 1/4 to 250.

SINGLE PHASE, THREE PHASE AND DIRECT CURRENT MOTORS • MOTOR GENERATOR SETS • ROTARY CONVERTERS • FANS AND VENTILATORS

FOR MORE THAN 28 YEARS AT ST. LOUIS
The individual tripping elements shall be enclosed and sealed in units of approved molded composition to eliminate tampering or unauthorized changes in calibration.

The circuit breakers shall have inverse-time-limit characteristics, so that tripping will be prevented on momentary overloads but will occur before dangerous values are reached.

—THEY'RE WRITING "tamper-proof circuit protection" INTO ELECTRICAL "specs"

Read the electrical specifications of many of today's modern buildings and you'll find, "The panelboards shall be of the Westinghouse Nofuze type"—for a rapidly increasing number of prominent architects are writing tamper-proof circuit protection into electrical "specs".

Only Nofuze panelboards can give this tamper-proof protection.

"De-ion" circuit breakers replace switches and fuses—eliminating all danger of overfusing or of substituting pennies, wire or hairpins for the protective devices. The calibration of "De-ion" breakers cannot be altered by unauthorized persons nor their opening action blocked. They cannot be held closed on abnormal overloads.

Here you have some of the reasons why Nofuze panelboards already are protecting more than 150,000 circuits and why they have been specified for so many of the important buildings now under construction.

Mail the coupon for the new 76-page Nofuze Catalog.
In 1909, the original building of the Toledo Museum of Art was erected. Revere Sheet Copper was specified and used for the roof.

In 1924, a new unit was added. Revere Sheet Copper was again selected.

In 1931, a second addition was made...two new wings. Revere Sheet Copper was specified...for the third time, making a total of 250,000 pounds.

Here is ample evidence (if evidence be needed) of the permanence, satisfaction, economy, and continued good appearance of Revere Sheet Copper. Added to this, Revere Copper is rust-proof, easily workable...a fine material for roofing, flashing, cornices, gutters, leaders, skylights.

But Revere Sheet Copper is more than utilitarian. It has beauty of finish; ornamental and "color" possibilities and "versatility" in decorative use...all of which make it a metal of truly inspirational character.

Companion material to this is Revere Leadtex...Revere lead-coated Sheet Copper. It has all the physical characteristics of Revere Sheet Copper...plus an additional range of decorative possibilities of its own.

For further information, address Revere Copper and Brass Incorporated, 230 Park Avenue, New York City.
No. 701
JONES & LAUGHLIN STEEL CORP., Pittsburgh, Pa. "J & L Junior Beam Floors for Residences"

This new booklet describes in detail a residential floor system of steel and concrete that is built around the J & L junior beam, a light weight, round, wrought copper bearing steel section. It may be used as the first floor of any house, or for all the floors of any house having solid masonry walls or steel framing. The starting advantages of the J & L junior beam floor system are that it provides "the same rigid, vibration-free, non-shrinkable support for the interior walls of the house that the foundations provide for the exterior walls. It acts as a complete firestop between the basement and the remainder of the house, and prevents moisture from rising through partition walls to the floors above. It is verminproof and impervious to the attacks of termites." It will eliminate, since it eliminates shrinkage, "plaster cracks in floors and ceilings, twisted door frames, uneven floors, and gaps between basement and flooring."

In the amply illustrated booklet are contained all the important details of the usual methods of installing the system, so that it serves as a practical design and construction guide, isometric diagrams, steel framing plans, photographs of installations, tables of sizes, weights, properties, and spacings, and all other pertinent information is given clearly and usefully.

In a typical installation with hardwood flooring the junior beams rest directly on the foundation. Sleepers (2 x 8 in. wood nailing strips) are secured to the steel by two plate clips at each point of contact. The two sleepers between the two plain steel reinforcing rods, 5/8 in. in diameter, are fastened to the beams. The concrete floor slab and the concrete fireplace along the foundation wall are then poured, imbedding the top flanges of the beams so that the beams, sleepers, and reinforcing rods are held rigidly in place. The hardwood flooring is then nailed directly to the sleepers.

No. 702
L. J. WING MFG. CO., New York. "Wing Safety Ventilating Fans"

A unique type of protective guard is one of the important features of the Wing ventilating fans described in this new pamphlet. Since it need not be removed to service the fan, it is permanently welded to the frame. The fan itself is of the screw-propeller type, and moves the air at practically the same velocity, both at the tip of the blades and at the center of the fan. The company manufactures a wide range of fans, for alternating and direct current, with diameters of from 93/4 in. to 66 in., high speed fans for industrial use, and pulley-driven fans for uses where motor-driven fans are not feasible. Complete information on sizes, prices, and construction are included in this pamphlet. Other products of the company briefly described are self-closing shutters, exhausts, unit heaters, process heating units, heater sections, and cooling fans.

No. 703
CELOTEX COMPANY, Chicago, Ill. "The Ferox Process"

By use of chemicals in what is known as the Ferox process, the Celotex Company is now manufacturing cane fiber insulating products that are practically impervious to the natural agents of decay and to the deadly, unseen attack of termites. The Ferox process coats each fiber before it is felted and woven with a chemical complex that is toxic to fungi, termites and other cellulose-destroying organisms. The chemical complex, according to the company, is insoluble in water, non-volatile, odorless, permanent, and in no way alters the physical properties of the finished products.

REVIEW: WORTHINGTON PUMP & MACHINERY CORP., Harrison, N. J. "Model GA Water Meter"

The Worthington Corporation has recently added to its line a new model water meter which is adapted to extremely low flows as well as to intermediate and high flows. Built in sizes from 1⁄2 to 2 in., with normal flow limits from 1 to 160 gallons per minute, the new meters are of the displacement disc type, all register gears being fitted with rubber-bushed bearings. The register box is fitted with a double lid to facilitate cleaning of the cover glass. The train assembly is composed of four cast bronze gears and four pinions, rigidly fastened to Monel Metal spindles which revolve in replaceable hard rubber bushings. Although standard construction provides for an inclosure for oil, the train easily may be converted to the open type by the substitution of an open train plate. It is said to be sufficiently accurate to record small drips and slow leaks.

No. 704
DURIRON COMPANY, Dayton, Ohio. "Duriron Exhaust Fans"

Bulletin No. 166 of the Duriron Company covers only the engineering and mechanical features of fans for the ventilation of laboratory hoods and other rooms involving fumes. As described in this bulletin, each fan casing is equipped with proper openings for the drainage of condensation. The fans themselves are equipped with oversize motors. In all sizes, all movable parts can be withdrawn without disturbing pipe connections.

The data given on each of the many different sizes and types of fans are complete, with dimensions, diagrams, capacities, and all other necessary information.

No. 705
AMPHOLITE INSTITUTE LABORATORY. "Bulletin No. 109"

The laboratory bulletins issued by the Ampholite Institute contain much information that is useful to all architectural offices specifying heating equipment in which Pennsylvania anthracite is to be used. This most recent bulletin pictures, discusses, and approves about forty different pieces of heating equipment, including automatic stokers, thermostatic controls, magazine feed boilers, service water heating systems, vacuum furnace cleaners, blowers, and registers. With the help of engineers of the Institute, and their findings are the basis for the discussions of each type of apparatus.

In this bulletin, for instance, seven automatic stokers are included, the Stoke Type "R," the Electric Furnace-Man, the Auto Coal, the Iron Furnace, the Losh Automatic, the Motorstoker, and the Motorstoker Coal Conveyor. Prices, capacities, and specific recommendations accompany each discussion.

E. GUTH CO., St. Louis, Mo. "Guthfan Conditioner"

The Guthfan Conditioner, introduced in this booklet, is a combination lighting fixture and ozone-laden air circulator. Prior to, the company had manufactured lighting equipment and the Guthfan, but in this product they have added the Guth Ozonator, which is built into the canopy of the fixture. The ozone drops from the lower part of the canopy when the unit is in operation and is distributed about the room by the fan. Each of the three elements, the lighting fixture, the fan, or the Ozonator may be bought separately, or in combination, to form the Conditioner.

The catalogue pictures and describes a wide variety of models, some with lights, and some without. Prices are also included. There are diagrams of the assembly of the units, and complete engineering information. The company makes a specialty of units for elevator cars, and there are several models shown for this kind of use.

Levy & Klein, architects, have removed their office from 218 North LaSalle Street, Chicago, to 415 Fourth Street, Wilmette, Ill. The new office will specialize in the modernization of homes.

Howard D. Fiedler, architect, formerly with William H. Brainerd Associates, has opened his own office at 89 Franklin Street, Boston, Mass. The new office will specialize in the modernization of homes.
The many useful variations produced in steel by different alloying materials and different treatments have become a marvel of the age. Changes of formula so very slight that no appreciable effect would be anticipated by the layman, often bring about incredible differences in character.

A relatively small copper content in steel has been found to heighten its resistance to corrosion, and specifically its resistance to atmospheric corrosion, to a marked degree. This has been proved in use as well as demonstrated by careful experiments, and is no longer in doubt.

Wherever pipe is subjected to alternate wet and dry exposure as in soil, waste, vent lines and rain leaders of large buildings, economy will be served by specifying NATIONAL Copper-Steel Pipe. The extra cost is trifling and the added length of service is appreciable. Write for Bulletin No. 11, describing NATIONAL Copper-Steel Pipe—

REVIEWS OF MANUFACTURERS' PUBLICATIONS

No. 708
BARBER-COLMAN COMPANY, Rockford, Ill. “An Electric System of Temperature Control”

In a booklet that is as interesting as it is instructive, the Barber-Colman Company describes the various types of electric temperature control systems that it manufactures. After explaining the elementary principles of automatic regulation, applications of their products to various heating, ventilating, and air conditioning plants are illustrated. Under separate headings, the workings of thermostats, valves, damper controllers, and motors are shown for direct radiation, unit heater, unit ventilator, direct-indirect radiation, indirect radiation, and warm air furnace installations. The method of presentation is orderly, and sufficient illustrations accompany the text to tell the story clearly.

All operations of the Barber-Colman devices are operated electrically, electric motor-operated valves and damper controllers governed by electrically connected thermostats. In explaining the working of the system, the pamphlet states, “The thermostat contains as its temperature-sensitive element a bi-metallic loop with an extension tongue which is free to move between two fixed contact points. When the thermostat calls for heat, the bi-metallic loop causes the tongue to make contact with one point, thus closing a circuit to the motor-operated valve or damper controller. The motor in the controller or valve, depending on the model, turns a shaft which operates the valve plunger or moves the damper, thus ‘turning on the heat.’ When the thermostat calls for stop, the expansion of the bi-metallic loop moves the tongue against the other contact, thus starting the motor again and closing the valve or moving the damper to deliver less heat.”

In addition to photographs of all the units which are employed in the system, there are several pages devoted to installation views and dimensions of units. The book is an extremely useful one to any architectural office.

No. 709
NEWMAN MANUFACTURING CO., Cincinnati, Ohio. “Newman Thresholds”

In this recent folder of the Newman Company, kick plates, and push and pull plates as well as thresholds are shown in diagram. There are more than fifty different kinds of thresholds, and the linear foot price and the dimensions are given for each. They are made of extruded bronze. Prices are also given for brass kick plates in widths from 8 to 24 in., and for several different kind’s of push and pull plates.

No. 710
FLOCKHART FOUNDRY CO., Newark, N. J. “Standard Construction Castings”

This is the 1932 catalogue of the Flockhart Company covering a wide range of gray cast iron products. These include various types of frames and covers, gratings, valve boxes, curb inlets, catch basins, heating element, the firing ens, clean-out doors, leader shoes, slide valves, lift valves, shear gate valves, and flap valves. Each of these items is covered by a separate data sheet, which contains all the information required, plans, sections, sizes. There are 32 pages in the booklet, and each page contains useful information.

Good news... 
FOR YOU 
and your clients

"STRAITLINE" Monel Metal sinks
at prices any home can afford...

8 reasons why you should specify Monel Metal "STRAITLINE" Sinks

1. Rich, lustrous beauty...with a satiny, glass-smooth surface.
2. Neutral silver tone that harmonizes with any kitchen color scheme.
3. Rust-proof...highly resistant to corrosion...easy to clean.
4. Solid metal...no coating to chip, crack or wear...strong as steel.
5. Surfaces give cushioning effect that protects dishes against breakage.
6. 3½% more work space than ordinary sinks of same nominal sizes.
7. Standardized sizes and models for every kitchen.
8. Prices within reach of every family purse.

Monel Metal is a registered trade-mark applied to an alloy containing approximately two-thirds Nickel and one-third Copper. Monel Metal is mixed, smelted, refined, rolled and marketed solely by International Nickel.

• Every family wants a Monel Metal Sink...and every family can have one now. The new Monel Metal "STRAITLINE" Sinks are here!

Fitting companions to the higher-priced "Streamline" models, the new Monel Metal "STRAITLINE" Sinks are designed, styled and priced to please thousands of women who have always longed for a Monel Metal Sink but never could afford one. They offer, at truly moderate cost, the beauty and durability that have been previously associated with kitchen sinks selling at much higher prices.

In these popularly priced sinks, the new "STRAITLINE" design and Monel Metal have been combined to give trim, modern beauty that is rare in any kitchen equipment...permanent beauty that grows with the years...and always harmonizes with every kitchen color scheme!

Such sensational sink value has been made possible only by volume production and advanced manufacturing methods. Monel Metal "STRAITLINE" Sinks have been created to meet today's economic conditions. As a result, you can now specify Monel Metal Sinks for every home you plan..."Streamline" models for higher-priced homes and the new, inexpensive "STRAITLINE" Sinks for the more modest ones.

Monel Metal "STRAITLINE" Sinks are now on display at leading plumbing supply houses. See them—and if you have not received your copy of the new illustrated catalog (A.A.S. file No. 29H6) giving sizes, specification data, etc., on Monel Metal kitchen sinks, we will be glad to send it upon request.

Iron Engineering is Born

About the year 1750, in England, there appeared the first example of iron engineering in its modern sense. For at that time, columns of cast iron were first devised.

The name of their originator is no longer known. In all probability, he was an ingenious millwright, for the cast iron columns were first employed in the construction of cotton mills in Lancashire. Their use established a style which was followed with but little alteration for more than a century.

It is likely that as a natural development of the experience gained in this use of cast iron for building columns, the possibilities of its extension into the field of bridge building were seen. In 1776, a cast iron bridge was constructed across the Severn at Coalbrookdale—the first real instance of complex iron engineering in England, and probably in the world.

Today, modern engineering relies on sections, a product of Illinois Steel Company, a subsidiary of United States Steel Corporation.
MODERN construction is constantly demonstrating the excellence and utility of AMERICAN Black and Galvanized Sheets for large installations in heating, ventilating, and air conditioning systems—as well as for general sheet metal work. KEYSSTONE quality (alloyed with copper) offers maximum resistance to rust, and excels for gutters, spouting, flashings, metal lath, and similar uses. KEYSSTONE Copper Steel Roofing Ternes are produced to give enduring service, protection and satisfaction.

Through every operation and at each stage of manufacture, this Company gives painstaking care to every element and factor entering into the production of steel sheets and terne plates of highest quality. AMERICAN products are sold by leading metal merchants. Write for information and literature.
IT IS TRUE that General Electric will present during July a revolutionary new type of oil heating, startlingly different and modern in principle. The result of five years' engineering research and one year's actual service in many homes, this new type of heating will offer entirely automatic operation... quick heat, accurately controlled... higher efficiency and lower operating cost... quiet operation... no soot, fumes, or odor... economical hot water supply the year round... handsome, compact design... and the overall guarantee of one responsible manufacturer — General Electric.

PROTECTS the careless passenger FROM FAST-MOVING, POWER-OPERATED ELEVATOR DOORS

How? By light beams? Yes—just that. No longer need injuries be caused by doors closing on the hurried or pre-occupied. Any one stepping in or out of an elevator or lingering in the path of fast-closing doors interrupts the light-beams. Instantly, the magic of Westinghouse Safe-T-Ray acts—the doors stop and re-open automatically. They stay open as long as even a small part of the clothing remains in the paths of the protecting beams which shine steadily.

A wonderful thing to see and consider—developed and applied for Westinghouse elevators by Westinghouse engineers. Speeding up elevator service in tall buildings requires fast-closing doors. The Safe-T-Ray permits this efficiency without accident.

Westinghouse, internationally famous for electrical achievements, is responsible for the present rapid development in the field of vertical transportation. Whatever your elevator problem—rely on Westinghouse.

_Fifty-eight Westinghouse elevators in the world’s largest office building will be equipped with the Safe-T-Ray. (The Central Tower of Rockefeller Center, “Radio City.”)_
