The terms "right-hand" and "left-hand" as applied to doors came into use in the days before some genius invented the "loose-pin" butt (and it is strange how many years passed before that simple and convenient discovery was made), when all

Some Building Terms Discussed—Sketches Showing Left Hand and Right Hand Butts

our butts were either "fast" butts in which the pin was riveted in, or "loose" butts, made in two pieces, one of which was in the form of a socket and the other of a hook, as shown in the sketch. As a result, they could only be used to hang a door to swing the way for which the hinge was designed. Hence it became necessary to agree on some designation that would mean the same thing both to the carpenter, the architect and to the manufacturer of hardware, so that the proper butts might be ordered to fit the doors. Therefore it came to be commonly understood that when standing before a closed door and it would swing around to the right when it was opened, it should be called a "right-hand" door; if it swung around to the left it was a "left-hand" door. With the advent of the loose-pin butts the necessity for the terms is not so pressing, though some of the more expensive locks are made in "right-hand" and "left-hand" styles and are not interchangeable.

In the matter of the "putty side of glass doors" there is not so obvious an answer to the question, and except in the case of doors made specially to be hung one way and no other, like fine outside doors or veneered doors—not alike on both sides—the carpenter must depend on his own judgment. As all doors, in the natural course of events, are subject to considerable slamming, it follows that if the putty side is put outside whenever the door

slams the weight of the glass is thrown against the putty with more or less force, and in course of time that will tend to loosen the putty and some day the force will be too much for it to withstand and out will go the glass, smash on the floor. Therefore, wherever possible, the putty side should be put on the inside. Of course, where the glass is put in with stops there is less danger of its jarring loose, but even then if the solid wood is put outside there will be more difficulty in evil-disposed persons removing the glass to gain entrance to the house.

Use of Oak Flooring in a Church

From Manufacturer, Rochester, N. Y.—In regard to the matter indicated by the above title, the correspondents "W. K.," Highland Park, and "Contractor," Moffitsville, N. Y., appear to contradict each other flatly touching the use of $\frac{3}{8}$ -in. oak flooring in a church laid over a good level sub-floor with felt between. Perhaps both correspondents are right, and the explanation is that they are not talking of the same thing.

Square edge flooring such as described by the Highland Park correspondent has a standard thickness of $\frac{5}{16}$ -in. In some localities this is known as $\frac{3}{8}$ -in. flooring. Technically it should be called a $\frac{5}{16}$ -in. parquet strip.

What is generally known as $\frac{3}{8}$ -in. flooring is tongued and grooved. The Moffitsville correspondent is probably referring to this. Flooring which is only $\frac{3}{8}$ in. thick and 2 in. wide is altogether too thin to be nailed only on the edge into the tongue as is other tongued and grooved flooring such as $\frac{13}{16}$ in. stock which he advocates. With his prophesy of disaster in the use of such flooring I fully agree.

I call to mind nine churches located in one city, and some of these are the largest churches of their denomination in the country, which are floored in a way which thoroughly proves the point that the $\frac{5}{16}$ in. square edge parquet strips constitute the best floor to give good results at a reasonable price in such large buildings. There are many more churches in the same city, the business managers of which have looked at the floors referred to and have in consequence had their own churches finished up in the same manner. Most of the parquet strips laid in these churches are $1\frac{1}{3}$ in. wide, while a few of them are 2 in. wide.

I think the Highland Park correspondent has had very bad luck indeed with the plain sawed parquet strips. He is absolutely correct in his statement that the quarter sawed material will give much better results than the plain sawed. I know of many floors laid with the plain sawed parquet strips that look very well, but conditions of sub-floor must always be ideal in the use of such material. Even under what seems to be the best of conditions the plain sawed parquet floor frequently goes bad. It is therefore much safer to follow the advice of the correspondent in question and stick to the quarter sawed material.

From J. T. B., Seymour, Ind.—Regarding the inquiry of "L. S." Dixon, Ill., concerning the use of $\frac{3}{8}$ -in. oak flooring in a church and the com-

ments thereon by "W. K.," Highland Park, Ill., and "Contractor," Moffitsville, N. Y., I wish to say a few words. The Highland Park man gave a conservative as well as a mechanical reply, while "Contractor" tells about botch jobs, etc.

Now tongued and grooved stuff and quarter rounds are made especially to cover up botch jobs. While 13/16 in. is all right for a common floor such as storerooms, warehouses and the like, I have no doubt that "L. S." wanted something artistic as well as durable. I know of a number of 5/16 in. square edge floors in hotel lobbies, churches, residences, etc., that have been installed for twenty-five years and am quite sure they are not "botched," but are giving entire satisfaction and look as well as new where properly cared for.

The proper floor to use is 5/16 x 1 1/3 or 2 in. No. 1 Q. W. O. If steam heated, use 1 1/3 in.; if hot air, 2 in., as the square edge is the proper thing to use in this flooring and my practical experience has taught me this fact. If Mr. "Contractor" thinks everybody botches floors other than himself, I can show him some of the most artistic floors in the Middle West, and if he will confer with some of the important manufacturers

he knows how to lay all kinds of designs of floors and finish to harmonize with any interior finish with which he may come in contact.

Removing Oil Stains from Marble

From D. P. B., Redford, N. Y.—I would say to "C. C. H.," Brookville, Pa., that he can extract oil stains from marble by making a paste consisting of 2 parts Fullers earth, 1 part soft soap and one part potash mixed with boiling water. Apply to the spots and let it remain three or four hours.

Elevations Wanted for Floor Plans

From Sawdust, Pasadena, Cal.—I have been a reader of THE BUILDING AGE and its predecessor for a long period of years, and now come to the correspondence department for a little aid from some of the other subscribers. I am sending outline floor plans of a small cottage I intend for my own use. My idea is to make the front gable 13 ft.

First Floor

Second Floor

Elevations Wanted for Floor Plans, Contributed by "Sawdust" of Pasadena, Cal.

in this line I have no doubt they can show him floors in 5/16 square edge that are not "botched."

Now if "L. S." will follow instructions of "W. K.," and see to it that his under floor is in good condition, and at the same time have a practical understanding of the method of laying and finishing floors he will come out all right, otherwise he is apt to "fall down," so to speak, on the job. There are thousands of very good carpenters in the country, but many of them know little about laying artistic hardwood flooring.

I have no use for plain or flat grain flooring. Always use Q. W. O. for a fine floor and there will be no trouble about warping. Use 1 1/4-in. brads No. 15 set down 1/8 in.; scrape thoroughly, sand and use a good filler recommended by the firm from which you get your floor.

I could go on and write much about the laying and finishing of floors, but I obtained my knowledge from attending expert floor lectures and experience of installing on my own account—not contracting. No man can become an expert until

wide and two stories in height. The side gables are to be 30 ft. with studs long enough so that the ridges meet with 1/3 pitch. That will mean lower ceiling on one side of the bathroom.

I want a wide projecting cornice, bungalow effect, with lots of light, and I would like to have some of the practical readers furnish elevations to fit these requirements. I will welcome criticism and any slight changes which the readers may suggest as desirable.

Another New York Theatre

Another theater, capable of seating 1,260 persons, is about to be erected on Broadway, just north of Forty-ninth Street, New York City, and is to cost about \$500,000. The plans of Architects Lord, Hewlett & Tallant, and William La Zinsk, provide for a twelve-story building, containing stores and studios in addition to the theater. The building is to have a brick, limestone and terra cotta facade.

Arrangement of Sliding Partitions

The Parallel Door Partition Which is One of the Three Principal Types—Various Details

BY E. J. G. PHILLIPS*

THE sliding partition is one of the creations of necessity, having been called into existence by the requirements of modern public buildings, such as churches with separate Sunday-school classrooms, public schools in which the smaller classrooms can be opened to form large assembly rooms, clubs, Y. M. C. A. rooms, libraries and other public buildings where provision must be made for small as well as large assemblages. By means of these movable partitions the same floor

This article will be confined to the discussion of several of the principal types, such as the parallel door, the accordion or folding sliding door, and the flush door partition. Large single doors are sometimes used, but these will not be discussed here.

An installation of parallel door partitions is illustrated in Fig. 1, which is a view of the Sunday-school room in a modern church and gives a good idea of the use for which the parallel door is best adapted. The balcony, as well as the space below it, is divided into individual classrooms by these movable partitions, yet when desired the doors are opened and the entire area is used as one room. A plan of this part of the building is given in Fig. 2.

In the parallel door partition, as indicated by the name, the doors slide parallel to each other and a separate track is provided for each door. The number of doors to each partition is not limited by the method of operation, but a better appearance is gained by using not more than two or three doors sliding in the same direction.

Fig. 1—View in a Sunday School Room Showing Parallel Door Partitions

Fig. 2—Plan of Sunday School Portion of the Church

Fig. 3—Plan and Elevation of a Parallel Partition with Wicket Door

Arrangement of Sliding Partitions—A Practical Example

space is made to do double service, increasing the usefulness of the building and yielding the greatest returns from the investment.

The large number of these partitions which are now being used and the importance of properly installing the doors and fixtures warrant a consideration of some of the essential features as well as of a few of the details of construction and operation of the different types.

The plan and elevation, Fig. 3, show a condition for which the parallel partition is well adapted. The two large doors form the partition between a small and a large room, and when not in use slide back into a pocket at the right. The pocket is built similar to that for an ordinary sliding parlor door, except that in all cases the sides should be covered with ceiling or other material to present a finished appearance, as in Figs. 5 and 6.

Door A laps the jamb at the pocket side and the two doors lap each other at the center of the open-

*Engineer Richards-Wilcox Mfg. Co.

ing. The track for door *A* extends only halfway across the opening, but door *B* requires a track entirely across the opening.

It is not necessary to slide all the doors one way, as they can frequently be arranged as in Fig. 4, where two doors slide to the right and two to the left. In this way an opening of considerable width can be obtained by the use of only two lines of track, and only two lap joints of the doors are visible. A pocket is here shown at each side of the opening; but this is not always necessary, and, indeed, there are many cases, such as in Figs. 1 and 2, where it is better to omit the pockets and use instead a stationary panel or door. This stationary door is built exactly like the sliding doors, but instead of hanging it on a track it is attached permanently to the floor and soffit. The sliding doors when opened occupy positions alongside the stationary door. This method results in a considerable saving of floor space and is particularly adapted for the smaller partitions such as are used between Sunday-school classrooms.

Partitions separating large rooms usually require a service or passage door between the rooms. If the doors are large, as in Fig. 3, the wicket door

Fig. 4—One of the Sliding Doors Used as a Passage Door

Arrangement of Sliding Partitions—Various Details of Construction

is the best solution. The doors should be built so that the wicket door will not destroy the harmony of design in all the doors. This is exemplified in Fig. 3. Hang the wicket with invisible hinges so that there will be no projections to interfere with sliding the larger door. The lock should be fitted with flush pulls instead of knobs.

A steel bar $\frac{3}{8}$ in. thick is used for a threshold. This is fitted into the bottom of the large sliding door *A*, and serves to tie the door together and helps to hold it in shape. A threshold strip with a double bevel or rounded upper surface is preferable.

One of the sliding doors can be used as a passage door if it is not too large. This is shown in Fig. 4, where one of the center doors is used for this purpose. A sliding door lock or latch is used to lock this door to the next one, which is held firmly in place by a flush floor bolt.

Details of the overlapping portions of the doors, together with a horizontal cross-section of the pockets, are given in Figs. 5 and 6.

The style of lap shown in Fig. 5 is very simple and serviceable. Wedge-shaped strips are attached

to the sides of the door and are so arranged that when doors are withdrawn the distance intended these strips interlock, prevent the further movement of the doors and make a tightly closed joint. It is essential that these strips be made wide enough to permit a firm attachment to the doors, as they are particularly susceptible to damage from rough usage. At *C* is detailed a tongue-and-groove joint suitable for use with these doors where they come together at center of opening, as in Fig. 4.

In Fig. 6 astragals are used on the edges of the doors. This method is often used with satisfaction, but has the disadvantage that no definite stop is provided. This will be more fully discussed in a later paragraph. At *D* astragals for the center joint for doors as in Fig. 4 are shown. For doors all sliding one way, as in Fig. 3, the astragal on the outer edge of the last door enters between two door stops attached to the jamb, as detailed at *E*.

Fig. 5—Details of the Over-Lapping Portions of the Doors

Fig. 6—Horizontal Cross-Section of Pocket

A typical vertical cross-section through the head jamb is shown in Fig. 7. The tracks are attached to the header, which is secured to the studding just high enough so that the bottom of the track brackets will be flush with the bottom of the trimmers. For doors $1\frac{3}{4}$ in. in thickness and not over 300 lb. in weight this distance will be about $3\frac{3}{4}$ in. Hangers for heavier doors require more space. Care in lining up these parts while roughing in the partitions will save considerable time when applying the trim. It is sometimes convenient to hang the tracks directly to the lower chord of a truss or to the ceiling joists, but the exact method must always be decided by conditions met with on the particular building under construction.

The casing and head trim are applied in the usual manner, but the soffits frequently present some difficulty to the builder. To make a neatly finished job the bottom of the tracks should be entirely covered excepting narrow openings through which the pendant bolts of the door hangers move. The outside soffit pieces are, of course, easily applied. The center strips are more difficult to apply, but a suit-

able scheme is shown in Fig. 7. The soffits are held in place by flat-head stove bolts which pass up between the tracks and through blocks of wood which rest on top of the tracks. This does not necessitate setting the tracks farther apart, because the bolts can be placed at intervals between the points where brackets occur and they take up no more space than the thickness of the track brackets.

Another method is to have the bottom of the track brackets drilled and tapped for small machine screws. The soffits can then be screwed directly to the brackets, but care must be taken to use screws just long enough to go through the brackets without lifting the tracks out of place.

Tracks of the trolley or box-shaped type are generally used. These are made in a variety of sizes to suit doors of any weight. The track shown in Fig. 7 is wood-lined and practically noiseless, and is therefore preferable for the lighter weight doors. The hangers are ball-bearing or roller-bearing, and are vertically adjustable.

Floor guides may be used to steady the bottom of the doors. This is particularly desirable where the doors are large. These are designed to compensate

Fig. 7—Typical Cross-Section Through Head Joint

pull set into each door will add to the convenience of operation.

(To be continued.)

A Modern Department Store Building

In connection with the annual review of building conditions, in the February issue of *THE BUILDING AGE*, we published, among others, a picture of the new Boston Store in Chicago, a building which is probably one of the finest examples of modern departmental stores in the Middle West. The structure is seventeen stories high and has three floors below the level of the sidewalk. It is supported on 123 piers, resting on the bedrock of limestone which underlies Chicago at a depth of 110 ft. below the ground level. The piers are solid concrete and vary

Fig. 9—Vertical Cross-Section

Fig. 8—Plan of Floor Guide for Steadying the Bottom of a Door

Arrangement of Sliding Partitions—Various Details of Construction

for any irregularity or unevenness in the floor. A suitable article is shown in Figs. 8 and 9. The flat floor strips *F-F* and the beveled strips *G-G* are of steel, and form the guide slots in which the rollers operate. The space between the steel strips is filled in with $\frac{3}{8}$ in. hardwood flooring, so that the top of the guides finish flat without any projections. If the floors are covered with $\frac{3}{8}$ in. hardwood flooring the beveled strips may be omitted and flat guide strips used all around. The guides will then be flush with the floors of the rooms.

The rollers are invisible, being entirely inclosed in the door. They are kept in contact with the guide strips by spring pressure.

A sliding door lock is shown applied to door *B* in Fig. 3, securing it to the jamb. Flush bolts are used to secure the bottom of the doors to the floor. When floor guides are used only one bolt or lock is required for each door. This should be set in the stile of the door farthest from pocket so that it will not interfere with the guide strips in the floor. The end of these strips should be a couple of inches back from the edge of the door to allow space for the plate with which the flush bolt engages. A flush

in diameter from 4 ft. to 13 ft., the average being about $8\frac{1}{2}$ ft., thus assuring a stable foundation.

The floor area of the building is approximately 25 acres. The floors and exterior walls are supported on steel columns, girders and beams. The building is faced on the street fronts with granite up to the third story floor, there being over 15,000 sq. ft. of granite, all highly polished. Above this work the structure is faced with glazed terra cotta.

The equipment is strictly modern in every respect. There are numerous elevators for passengers and freight, two of which are capable of carrying the store's heaviest auto trucks with their entire loads to the sub-basement or any of the seventeen floors. By means of these van elevators, delivery trucks are loaded inside the building, helping to eliminate the congestion of traffic on the adjoining streets and alley. In the second sub-basement is the mechanical equipment which furnishes the power for the operation of the elevators, ventilation, heating, electric current, vacuum cleaning, etc.

It is interesting to note that the sub-basements, basement and first floor are provided with a ventilating system by which pure air is distributed to

all sections of the building. The air is washed, cooled or warmed, as the case may be, and is supplied in volume that exceeds the specifications laid down by the health department.

The Boston Store occupies the site of the old Champlain Building, and it is recorded that only 34 working days were consumed in demolishing this structure. In the new building 9000 barrels of Marquette Portland cement were used. Plans and specifications were prepared by Holabird & Roche, architects, Chicago, Ill., and the general contractors were John Griffiths & Son Co., of the same city.

Making Shiplap Columns

The shiplap column is made without gluing or turning. The staves are made on the molder, and the everyday carpenter can put them together without clamp chains or any other methods usually used in gluing columns, says C. S. Houston, in a recent issue of the *Wood-Worker*.

Put the columns up in halves and use finish nails, as shown in the cross section at B. The joints can be nailed with corrugated nails, as shown at A. The

Section Through a Shiplap Column

column can also be nailed all the way round with ordinary as well as the corrugated nails. This makes a very nice outside column, and in a great many cases it can be finished up neat enough to use inside.

The sketch shows end view of the column, put together with corrugated nails. It can be made of 2 x 4 lumber. A scale for making it is, to take the width of the largest end in inches and figure one stave to each inch. This scale will allow one to use 2 x 4's; the width of the staves will average from 3 to 3½ in. When making a column 7 in. across the end, it takes seven staves 3½-in. wide, and a column 10 in. across will take ten staves, and so forth.

When working up this column make a sketch of the end, as shown, to get the angle of the staves. If they are open a little on the inside it will not show on the outside, on account of the shiplap joint. This is a simple column and can be made by almost any mechanic. The advantage of it is that it does not have to be turned; it is run with a round race, on the molder, which saves time and labor.

A base and cap can be easily made by cutting it

round on the band saw and shaping it on the shaper. We use this method where there is no turning lathe, and find it works perfectly. One of the largest and finest churches in Corsicana, Tex., has columns of this style on it.

Novel Commercial Building Architecture

For some time past active building operations have been in progress on the sites of the old Hoffman House and Albemarle Hotel, at the corner of Broadway and Twenty-fourth Street, New York City, and today there stands a sixteen-story structure which embodies in its architecture several features of novelty. In the building, now rapidly being completed, the first three stories will be utilized for display purposes with iron, glass and limestone front, giving something of a monumental effect. The other stories will be used as lofts. Above the fourth story the façade will be of light ornamental brick, with terra cotta panels.

Another feature of the design is the corner angle at the junction of Broadway and Twenty-fourth Street, which is what in building parlance might be termed "chamfered," with a bold parapet treatment, giving a sharp sky-line and which will take the place of a cornice.

Still another feature is a service driveway, 40 x 80 ft., permitting the largest trucks to drive into the building to unload their freight. The plans were prepared by H. C. Severance and William Van Alen, who place the cost of the structure at \$1,350,000.

The Use of Fans in India

It is now possible through the introduction of the electric fan in India for theaters and churches in cities like Bombay to be open all summer, whereas formerly, owing to the almost stifling heat, it was very difficult to induce people to enter such structures in that season. The popularity of such places is now largely dependent on the number of efficient electric fans to force a constant circulation of air. All the leading hotels in the chief cities of India must have electric fans in every room in order to secure and retain their patronage.

The old-fashioned system of cooling rooms by fans in this country, such as is still practised in most communities where electric current is not available, as in country districts, is by means of the personal labor of coolies who work spacious fans hung from the ceilings, with ropes through a hole in the wall, the punkahwallah doing this work outside of the room out of sight.

Spirit stove fans are also used in India. These are attached to and operated by small spirit stoves, especially in country bungalows and in tents, where no electric current is available.

These spirit-stove fans, often mounted on tripods, have added immensely to the comfort of trips into the jungles and in camp life generally. They can be easily packed for transport by mules, elephants, carts or boats, as the case may be. They sell according to size from \$20 up to \$50. A leading firm dealing in these fans advertises that there are over 20,000 Europeans in India using them.

As an instance of the popularity of electric fans

in India, it may be mentioned that one leading corporation at present has connected to its system over 40,000 fans. The United States is one of the most important sources of supply.

In building the new government offices at Delhi artificial cooling on a much larger scale than can be obtained with individual fans is to be undertaken, Mr. Baker, United States consul, tells us. It is understood that the authorities having charge of this work are considering the possibility of constructing buildings with inner and outer walls between which artificially cooled air can be circulated by means of exhaust fans, the cooling being effected by drawing currents of air through wetted screens.

It is thought that possibly by such cooling of the walls during the heat of the day, when the buildings would for the most part be closed up, conditions of comfort might be considerably promoted.

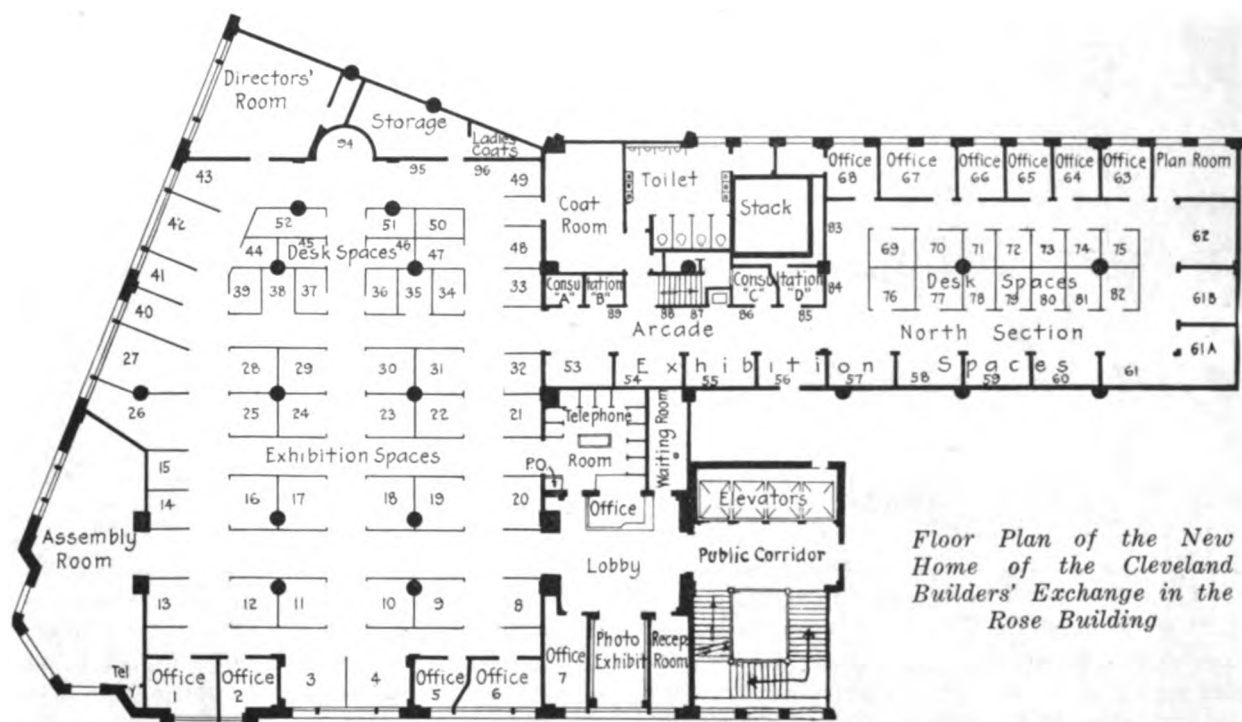

New Home of Cleveland Builders' Exchange

A short time ago we announced in these columns the fact that The Builders' Exchange of Cleveland, Ohio, was soon to occupy more commodious quar-

about 15,000 sq. ft. as compared with 6,200 sq. ft. in the old quarters of the Exchange.

The entrance to the Exchange is through a wide doorway from the main corridor of the third floor reached by four large elevators giving adequate and rapid service. Inside the door is a lobby, adjacent to which are accommodations for attendant and telephone operator on the one side and the reception room on the other. The main aisle 9 ft. wide extends to the southeast corner of the floor, where is located the daily Assembly Room, all as clearly indicated on the plan. The central space is devoted to desk room and exhibits, while other portions are given over to offices inclosed with partitions, this being a new feature of the Exchange. A large coat room and lavatory, directors and committee rooms, a plan room and several consultation rooms with desirable wall space for exhibits combine to make the new quarters much more pretentious and satisfactory in every way than were those in the Chamber of Commerce Building.

An important feature of the new quarters is the permanent exhibit of building materials, the exhibition spaces being clearly indicated on the floor plan. This scheme affords a medium for the dealer to establish a direct relationship with the members

Floor Plan of the New Home of the Cleveland Builders' Exchange in the Rose Building

ters in the Rose Building at the corner of East Ninth Street and Prospect Avenue. The removal is expected to occur on May 1, and we take pleasure in presenting herewith a plan of the third floor of the building in question showing the general layout of the Exchange rooms. This plan, however, does not show space comprising 2,300 sq. ft. on the fourth floor of the building to be used for association meetings, library and general purposes, etc., and is reached by the stairway which rises from the arcade. On the third floor of the building the Exchange has leased for five years 12,500 sq. ft. with the privilege of two extensions for additional five-year periods. This gives a total of

of the Exchange, the architects who visit the quarters, citizens who contemplate the erection of buildings, the city, county and state officials, and a wide range of visitors both from Cleveland and its suburbs as well as from other cities throughout the country. A lively program of association meetings, committee sessions, public and semi-public conferences, luncheons and other features bring to the Exchange from week to week a large and representative patronage all of whom are interested in looking about and getting new ideas. This scheme of permanent exhibit of building materials has been adopted on a large scale in New York, Philadelphia, Chicago, Baltimore, Detroit and other cities.

A Little Geometry for the Carpenter

A Few Simple Problems Often Used by the Enterprising Building Mechanic in His Trade

By W. S. WILKIN

IN connection with the average work of the carpenter, the joiner and builder, instances are constantly arising which involve simple geometrical problems, and in the present article I shall deal with work which is mostly done with the compass dividers and the straightedge. In Fig. 1 of the diagrams we have a simple problem with which many of us are familiar. The idea is to establish the line $A-B$ at right angles to $C-D$. For small work the steel square will answer very well, but for large work where the lines are long the method here shown will be much more accurate for the trammel points may be used on a rod 6 or 8 ft. long. If the line $A-B$ does not have to cross the line $C-D$

not be used, and if the door was 8 x 8 ft., or something like that, the steel square would not prove very accurate unless the door was jointed perfectly straight. The method here shown, however, is quick and accurate. The line $H-G$ may represent the edge of a door or a pencil line, this being entirely immaterial. Mark the point from which you wish to square as G , then with any radius and any center as I , just so the pencil point cuts at the point G , strike the arc $F-G-H$. Next place a straight edge so it touches the point H and the center I . Draw a line and it will cut the arc in the point F . Now with the straight edge draw the line $F-G$, which will be perpendicular to the line $H-G$.

Fig. 1—Establishing a Line at Right-Angles to Another Line

Fig. 2—A Good Method for Use When That Shown in Fig. 1 Is Not Convenient

Fig. 4—Showing How to Duplicate the Angle in Fig. 3

Fig. 3—Method of Bisection of an Angle

A Little Geometry for the Carpenter

at any certain point, take any radius, and with a center anywhere on the line $C-D$ strike an arc both above and below the line. Next take another center on the line $C-D$ and strike another arc both above and below the line intersecting the first arcs. Then, on the straightedge draw a line through the intersecting points and the result is a line exactly perpendicular to the other.

If the line $A-B$ must cross the line $C-D$ at a certain point, as, for example, at E , take E as a center and with any radius strike arcs cutting the line $C-D$ at the points C and D . Then with C and D as centers and any radii, strike the arcs as explained before. Now with the straightedge draw the line $A-B$ which will pass exactly through the point E .

In Fig. 2 is indicated a good method to occasionally use when that indicated in Fig. 1 cannot be employed. Suppose we wish to square up a large door. It would readily be seen that Fig. 1 could

In Fig. 3 is shown how to bisect an angle to find the miter cut for a molding to fit in that angle. Let $J-K-L$ represent the angle, and with any radius with center at K strike the arcs at J and L . Then with the same, or any other radius, and with centers at J and L strike the arcs intersecting at M . The line $M-K$ will then be the miter line.

In Fig. 4 is shown how to duplicate the angle in Fig. 3. Draw the line $L'-K'$, then with the radius equal to $K-J$ of Fig. 3 strike the arc $J'-L'$, using K' of Fig. 4 as center. Now with L of Fig. 3 as center, and with a radius to just cut in the point J , move over to Fig. 4, and with L' as center, and the same radius, strike the arc at J' . Now draw the line $J'-K'$, and it will be seen that the angle $J'-K'-L'$ is similar to $J-K-L$ of Fig. 3.

In Fig. 5 is shown a quick way of laying off an octagon in a given square. Let $N-O-P-Q$ represent the square. Draw the lines $N-P$ and $O-Q$ which

give the center. With O as a center and $O-R$ as radius, strike the arc $S-R-T$. Again, with N as center, strike another arc and so continue from all four corners. Draw the lines across the corners as shown and the result is the octagon.

Fig. 6 shows how to lay off a hexagon. With W as center, strike a circle, then draw a straight line through the circle in any direction just so it passes through the center as $U-W-V$. With the same radius as the circle, and V as center, strike the arcs at X and Y , then with V as center strike the arcs shown and from the points thus far found draw the sides of the hexagon. It must be remembered that the side of the hexagon is the same length as its radius. I will try to explain why. A circle has 360 deg., and 360 divided by the number of sides in a polygon always gives the central angle. A hexagon has six sides, therefore, 360 divided by six gives 60 deg.

seven sides. First draw a straight line as $7-b-c$. Then, with a radius equal to the length of the side, and with center at b , strike a semi-circle as shown. Divide it into as many equal parts as the polygon is to have sides—in this case 7. The line from 7 to b represents one side. Now draw a line from b to 2 which gives us two sides. With a center at 2 strike arcs at d and e . Next with b as center, strike arcs at d and f , also at g and e . Next with 7 as center strike arcs at f and g . Now draw a line from d to e , also one from f to g , and where these lines intersect, as at a , will be the center of the polygon. Now with a as center and $a-b$ as radius, draw the circle. Next draw a line from b through 3, and from b through 4, etc., which will locate the point at the circle. A better way, however, is to set the dividers at 7 b and step around the circle, then draw the sides as shown.

Fig. 8—Drawing a Circle Through Any Three Points Not in a Straight Line

Fig. 6—Method of Laying Off a Hexagon

Fig. 9—Finding the Radius of a Circle When Chord and Height of Segment Are Given

A Little Geometry for the Carpenter

as the central angle at W . A triangle, regardless of its shape, or the length of its sides, always contains two right angles, or 180 deg. In a hexagon we have six triangles, one being shown at $W-X-V-W$ in a regular hexagon. We know the angles at X and V are the same, and we have already found the angle at W to be 60 deg. Now 180 minus 60 equals 120 deg., in the two outside angles and as both are equal, so 120 deg. divided by 2 equal 60 deg. in each of the angles at X and V , which makes all the angles equal. If all the angles are equal, all the sides must be equal, and if all the sides are equal, the radius of a hexagon must be the same length as its sides, Q.E.D.

In Fig. 7 we show a method of laying out any regular polygon when the length of the sides is known, "without the use of a protractor." In this case it is a hexagon which has

Fig. 8 shows how to draw a circle through any three points which are not in a straight line. Let $a-b-c$ represent the three points and we desire to find the center. This is accomplished as in Fig. 7 by taking three centers and drawing arcs as indicated. Then draw the straight lines and where they intersect will be the center.

This may be something which will not be used very often, but is worth remembering, as every carpenter should know how to do it.

Fig. 9 is a diagram for finding the radius of a circle when the chord and height of segment are given. If it were not too large the method shown in Fig. 8 could be used by laying off the chord the given length and using a and b as centers, together with any radius, using the method in Fig. 1. This will bisect the chord and make the line $c-d$ perpendicular to the chord. Mark the height of the seg-

ments on this line and $d-c$ and b will be the three points from which to work to find the center which will give the length of the radius. If the work was large and a good floor on which to lay it out was not available, it would be much better to use the formula, then the trammel points could be set and if it was a form to be built up of boards one piece could be laid off from a pattern and the rest cut from that. In this way it would not take so much floor space on which to do the work.

Two formulas are here given for finding the radius when chord and height of segment are given.

C = chord

H = height of segment

R = the radius

$$R = \left[\left(\frac{C}{2} \right)^2 \div H + H \right] \div 2 \quad R = \frac{C^2 + 4H^2}{8H}$$

Figs. 10, 11 and 12 show three ways of drawing an ellipse. Figs. 10 and 12 represent a true ellipse,

Fig. 10—Drawing a True Ellipse

Fig. 12—Drawing an Ellipse with String and Pencil

as a radius, and with e as center mark the major axis at g and h . With $g-h$ as a side, construct two equilateral triangles by using g as center and $g-h$ as radius. Draw the arcs at i and j , then with the same radius, and h as center, draw another arc at i and j . Next draw the lines $i-g-n$ and $i-h-n$, also $j-g-l$ and $j-h-k$. Now with i as center and $i-d$ as radius, draw the arc $m-d-n$. Next with j as center and the same radius draw the arc $k-c-l$.

Now we cannot use g and h as centers to draw the two ends, for if we use $g-l$ as radius it will not quite reach b . I have shown two ways to find the centers for the ends. At the right end use $1-b-n$ for the three points and find the center as shown in Fig. 8, which is at o . With this center and $o-l$ as radius, draw the arc $1-b-n$.

At the left end I show two centers to find, which take a as center and $a-k$ as radius and draw the arc $k-q-p-m$. With the same radius and k as center mark at p . Then with m as center and the same radius mark at q . Then with q as center and the same radius, draw the arc $m-a$. Next with p as center and the same radius draw the arc $a-k$, which, it will be seen, makes a very good ellipse.

Fig. 12 shows a quick way of drawing a true ellipse with string and pins, draw the lines $a-b$ and $c-d$ at right angles to each other. With c as

Fig. 11—Drawing an Ellipse with Circular Arcs

A Little Geometry for the Carpenter

and Fig. 11 an ellipse that is nearly true, but not quite. This is, however, often used in laying out large work such as making forms for large arches, etc. Referring to Fig. 10, draw $a-b$, the major axis, and $c-d$, the minor axis. With e as center draw the quarter circle $c-f$. Divide $e-f$ into any number of equal parts as 1, 2, 3, etc. Then divide $e-b$ into the same number of equal parts at $1', 2', 3'$, etc. Next draw $1-g$, $2-h$, $3-i$, etc., and then draw lines perpendicular to the major axis as $1', 2', 3'$, etc. Make $1'-g'$ equal to $1-g$, and $2'-h'$ equal to $2-h$, etc., as shown, or using the dividers and marking the points all around on all the lines. Now trace the curve through these points as shown.

To draw an ellipse as with circular arcs, as in Fig. 11, lay off $a-b$ and $c-d$ as indicated. Lay off $a-f$ on the major axis, the same length as $c-d$. Divide $f-b$ into three equal parts and take two of them

center and $e-b$ as radius, mark the major axis at g and f . Place pins at these points and fasten on string at f , placing a pencil point at c . Draw the string around it tight, and wrap it once or twice around the pin at g , and hold it down with the thumb, keeping the string stretched tight with the pencil. Trace the curve $a-c-b$ and trace the lower half in the same way. The string will be just the length of the major axis.

While I may not have explained this work just as it should be, I think the drawings will speak for themselves so that the reader will readily understand them. Even though he does not have use for these problems at the present time he should preserve his copies of THE BUILDING AGE, as I suppose most readers do, because there may come a time when it will be convenient to refer to the problems for the purpose of finding just what is wanted.

A Modern Fire-Resisting Cottage

Walls, Floors and Roof of Reinforced Concrete Construction—Many Details of Interest to the Builder

THE prevailing tendency in home building at the present time, especially in those localities where fire protection is limited and the hazard correspondingly great, is more and more in the direction of a style of construction calculated to resist the spread of flames. It is well known that concrete serves an excellent purpose along this line and that a frame superstructure can be rendered in large measure fireproof by the proper application of this material. A most interesting example of what can be accomplished by such a combination

The cellar extends under the entire area and has a cement floor. Framing timbers consist of 2 x 6 in. yellow pine sills with corner posts made of two pieces of 2 x 4 in. yellow pine; rafters 2 x 6 in. spaced 16 in. on centers, and the main girders supporting the first floor are of 8 in. I-beams weighing 18 lb. to the foot and supported by two pipe columns 4 in. in diameter. The girders supporting portions of the second floor are constructed of 2 x 8 in. joists spiked together.

The first floor joists are of 2 x 12 in. yellow pine

A Photographic View of the Cottage of Mr. L. R. Hildreth at Walnut Hills, Ohio—Architects and Builders, Newcomb & Jenkins, Cincinnati

of materials with metal reinforcement is illustrated herewith, the house being located in one of the many attractive suburbs of which the city of Cincinnati can boast.

The cottage is 1½ stories in height and provides upon the main floor a living room of generous proportions, a dining room, a kitchen, one bedroom and a bathroom. On the second floor are three sleeping rooms, two of which are of unusual size and provided with commodious clothes closets. There is also a bathroom on this floor.

spaced 20 in. on centers, while the second floor joists are 2 x 8 in. yellow pine spaced 16 in. on centers. The rafters are 2 x 6 in. spaced 16 in. on centers. All floor joists are stiffened with rows of 2 x 1 in. bridging.

The interior and exterior wall studs are covered with No. 28 Keyridge sheet metal reinforcement placed with the smooth side out to receive the plaster. This material has perforations in the sheets which are burred out and overlap each other at an angle of 45 deg. This causes a series of truss shaped

projections or flanges which give great rigidity to the finished work.

The exterior walls, as will be seen from the half-tone engraving upon the first page of this article, are finished with stucco applied to sheet metal reinforcement. The scratch coat was made of one part cement, $2\frac{1}{2}$ parts clean sharp sand and $\frac{1}{2}$ part slacked lime. The second or finish coat was made of one part cement and two parts of sand with hair in the proportion of one bushel to one bag of cement.

The construction of all interior walls and par-

ers embedded, to which to nail the wood flooring. An idea of the construction may be gathered from an examination of the detail presented herewith.

Some of the partitions throughout the house consist of a double wall or are solid and 2 in. thick. Where the solid partitions were used the Keyridge sheet was fastened at the floor and at the ceiling and run in a vertical position. A temporary wooden support was extended through the center partition horizontally and well braced from the floor, this support being removed after the first coat of plaster had been applied.

The stairs were also reinforced with Keyridge, the sheet being bent to take the special form of each stair. The concrete was then applied with a trowel to the proper thickness.

The concrete slab for the roof was applied in the same manner as that for the floor. In order to

Second Floor Plan

Main Floor Plan
Scale 1/16 In. to the Foot

A Modern Fire-Resisting Cottage—Newcomb & Jenkins, Architects and Builders

titions consists of Keyridge on wood studs, the latter being placed 16 in. on centers. Regular standard mixture of plaster was used for the interior partitions, which are tinted a cream color and have a sand finish. All plastering was applied to the smooth side of Keyridge and all corners were protected with "Edmanco" corner beads.

On top of the floor joists were placed No. 24 Keyridge sheets having the groove side up. On this was placed two inches of concrete with wood sleep-

Details Showing the System of Construction That Was Used

provide nailing grounds for the roofing tile small strips of wood were embedded in the concrete at the proper distance on centers so that each and every tile could be securely nailed and held permanently in position. The roof was covered with Edwards Metal Spanish Tile, which are made from a special brand of tin plate and are 10 x 14 in. in size. All metal tiles were given a good coating both sides of special "Edmanco" paint in exact imitation of grey tile in color.

Interior of the Dining Room with a View of the Living Room Beyond

The floors in the rooms of the main story are double. The sub-floor consists of sheathing boards running diagonally and nailed to the sleepers embedded in concrete, and then on top of them were

placed the finish floors of hardwood. The rooms in the second story have 2-in. yellow pine flooring.

The wood trim in the living room and dining room is of quarter sawed oak finished in fumed oak.

A Modern Fire-Resisting Cottage—View in the Living Room Looking Toward the Open Fire Place

The beam ceiling is of similar finish in both rooms. The dining room has a plate rail to match the balance of the finish. The kitchen and the bedroom on the first floor have white pine trim.

The rooms on the second floor have white pine trim treated with three coats of white lead well rubbed and a finish coat of white enamel with mahogany stools and picture molding. The doors are also finished in mahogany.

A house constructed as here described is fire-resisting to an extent to assure low rates of insurance and is especially adapted for the rural or suburban districts where fire protection is usually found in a limited degree.

The cottage was erected for Louis Robertson Hildreth at Calvin Cliff, Walnut Hills, Cincinnati, Ohio, in accordance with plans prepared by Newcomb & Jenkins, Cincinnati, who were both the architects and the builders.

The Keyridge Reinforcement as well as the Metal Spanish Tile were furnished by the Edwards Mfg. Co., 423-443 Eggleston Avenue, Cincinnati, Ohio.

Graduation Exercises of the New York Trade School

The thirty-fifth annual commencement of the New York Trade School, Sixty-seventh Street and First Avenue, New York City, was observed with appropriate ceremonies on the evening of March 29 when graduates, relatives and friends filled the auditorium to overflowing. The guests of honor included members of the Board of Trustees and representatives of the trade associations.

The exercises were opened by President R. Fulton Cutting, who in his usual graceful manner and in well-chosen words urged upon the graduates the fact that their future depends upon the proficient, honest and intelligent application of the training gained in the school. Many employers have no idea of trade education, but they can be shown what the trade school education means by the work graduates do. There is plenty of room at the top, and to get there, even under fair competition, means hard, honest work. Persistency and determination are essential factors—only through the exercise of honesty, sobriety and persistency in trade work comes success. A large number of graduates are now employers. With these ideals uppermost in the mind, and with a good character success is assured. Graduates were advised to join the trade union, which is a protection against conscienceless employers, even though it has narrow views on trade education. "Keep your heads sound and clear," he said. "Remember that you had the advantage of training, and influence the unions to take a broader view of this subject."

Prof. Charles A. Beard of Columbia University made the commencement address, in the course of which he related instances from the life and work of Abraham Lincoln to inspire the young man ready to take up their life work. He pointed out that Lincoln was not in a log cabin of the poorest type. His father was a worthless man, and his mother died when Lincoln was still a child. From his step-mother the boy first learned of industry, courage and hope. He was truly educated in the school of

adversity—he was self-taught. He studied not many books, but few. He spent hours at study alone in his poverty and adversity, and there he gained the virtues that perpetuate his name as that of a great American. Courage, patience, charity and humor in times of adversity were among his great qualities. It has been truly said that out of Abraham Lincoln's life have come the "vibrations of deathless music."

The total number of graduates for the season was 115, of which 72 were in the day classes and 43 in the evening classes.

The "honor" man of the carpentry class was William Miller of Brooklyn; of the class in plastering, Ernest Greenhalgh of West New York, N. J.; of the class in sheet metal work, William R. Yunker, Newark, N. J.; of the steam fitting class, William G. Knoll of Brooklyn; of the class in sign painting, Frederick Rieger of New York City.

In the electrical class the honor men were:

John E. Hoey, Jr., Ridgely Park, N. J.
Howard M. Halpin, Bethel, Conn.
Frederick L. Kirk, Bethel, Conn.
Peter F. Reynolds, Jr., Astoria, L. I.

The honor men in the plumbing class were:

Fred R. Robertson, Bayside, N. Y.
Eugene J. Miller, Elmira, N. Y.
James M. Cawley, Wilkesbarre, Pa.
Philip G. Armknecht, Elizabeth, N. J.
Nathan Klein, Taunton, Mass.
Alvin Frevert, Lindenhurst, N. Y.
William H. Grau, Rensselaer, N. Y.

The annual prize given by the Manhattan branch of the New York Master Plumbers' Association for proficiency in plumbing was a gold medal in the form of a Maltese cross on a circular background suspended from a horizontal bar bearing the name of the school. In the center of the gold field was the seal of the association surrounded by a blue circle bearing its name. The reverse side, inscribed with the winner's name, stated that the medal was for good workmanship, knowledge of plumbing theory and practical application. The medal was presented to Fred R. Robertson, son of Fred Robertson, a master plumber at Bayside, L. I. The exercises were brought to an end by the order of singing "America," after which the work of the students was inspected by the visitors.

Big Buildings for Brooklyn

Among the improvements recently commenced in Brooklyn mention may be made of three large reinforced concrete loft buildings, one of which will cover an area 200 x 125 ft. and rise twelve stories in height, while another will cover a site 460 x 75 ft. in area and rise six stories in height. The third building is a twelve-story and basement factory, 101 x 106 ft., which will occupy a site on Washington Street facing the Brooklyn Bridge. The plans have been prepared by Architect William Higginson, 13 Park Row, New York City, and the contract for the work has been let to the Turner Construction Company, 11 Broadway, New York.

Plans have been filed by George & Edward Blum, architects of New York City, for a twelve-story loft building to be erected in West Thirty-eighth Street, at a cost of \$250,000.

Cabinet Work for the Carpenter

Constructing That Comfortable Piece of Furniture Known as the "Day-Bed"—Various Details

BY PAUL D. OTTER

THE "day-bed" is an ancient form—"used for rest during the day; a lounge or sofa," as the dictionary tells us. There is no other form of furniture which is being brought back from the past with more reason. Our present day is lived so fully and intensely that there is need of putting on the brakes, slowing down and coming to a distinct pause at sometime midway of bedtime. A couch, sofa or davenport, located in one of the lower rooms of the home is a provision which will meet not only the requirements of modern furnishing, but will ever offer a haven of rest if not a hasty nap, when the spirit lags, or time does not permit one to retire for rest in bed. Did you ever notice that in some—men and women—daily vigilance is so imperative that it is thought unmanly, or suggesting weakness, to seek a bed in daylight? No! Fatigue and nerve weariness must be lived through

Again, it would be better to err in a final upholstery height of say 16 in., rather than over 18 in., where such a deep seat is concerned. You will observe that beyond the height of the side rail *E*, the upholstery height will be somewhat dependable upon character of mattress *F*, and the tension of spring work supported by slats *D*.

With some it may not be possible to have the frame furnished by a skilled upholsterer, and with this in mind a simple substitute method is given which will present a becoming outward appearance. For this reason the upholstery description precedes the description of what will prove a very simple piece of woodwork in the hands of an interested woodworker.

The plan suggested, to avoid expense of special made mattress, or box mattress with over-mattress, is to cut down a regular bed mattress to a width of

Cabinet Work for the Carpenter—Fig. 1—Front View of a "Day-bed"

unrelentingly until the customary bedtime, when the bed in the upper room relieves the body from fatigue and the mind from the cares of the day.

The revival of the "day-bed" is not to reproduce it in the proportions of a bed, but more to bring back its usefulness and hold to its full body length of not less than 6 ft. between ends.

Its depth of 33 in. is ample to preserve a proper form for the living room, large hall or sun parlor. With these proportions it has a dual purpose as a sofa for several persons, or a full length reclining couch, which also can be used in a comfortable way at night on occasions when all bed rooms are occupied. With this double purpose in view, the principal aim should be to have its height from the floor made the same as a comfortable upholstered arm-chair, allowing for such a large piece as this to be fitted with casters. It might be well then in laying out a working detail drawing to secure the casters to be used, or know their height, for there can be no cutting off of legs in this form of "spade leg."

30 in. There are few homes where a used mattress may not be used for this purpose.

A sharp carving knife drawn several times along a straight edge will sever the material at the proper width. A new facing of ticking may then be very readily box-edged in like manner to the other three sides by any needlewoman.

This will give a mattress 3 ft. x 6 ft., and presumably 4 or 5 in. in thickness, depending on quality of original filling. As for a suitable and becoming cover or spread to mattress there are many cheap to expensive patterns of made-up couch covers running from jute to expensive tapestry material. In connection with the selection of the cover, it is possible to select an appropriate piece of goods for both ends, inside and out, which will match in character, or be of the same tone as the cover to the mattress. Denims and terry of a good grade are very satisfactory also, for covers and ends.

Differing from the covering of the bed mattress, the spread in this case will completely envelop the

edges, and the surplus be tacked under the mattress, or disposed of on the inside of the rail, which will enable the cover to be removed frequently. You must know your mattress thickness so that the rails *E* will not be more than 3 in. below its surface or sufficient to contain it without exposing the under part. Should the rails be too high, a person of some weight will depress the mattress and springs to the uncomfortable striking point.

Now for the system of springs which support the mattress, for it is a system of five springs to a slat (*D*) depth, and nine rows in length. Each spring with a slight padding of burlap is secured with staples to the slat. With a disposition of slats and springs properly spaced, the upper control of the springs may now be started from the back to the front. Cutting nine pieces of heavy twine to a generous length for back to front springs, cut also five full lengths for end-to-end springs. You will observe the purpose is to so start tying with a surplus end of twine that each top of coil spring will be tied and caught up on the opposite side with a knot, and with care in holding the spacing correctly, pass on from back to front spring of first slat leaving hang ample surplus of twine. The "springing up" work begins from the back to front

Cabinet Work for the Carpenter—Fig. 2—End View of "Day-bed" with Detail of Foot and Scroll End

by driving a 10-oz. tack at end of cleat *D* to which, before driving in, fasten twine with a slip knot, then drive home and lock with another well directed tack. Draw the twine upward, meanwhile pressing the first spring down about 2 in., engaging the top coil wire with a slip knot on the outside. Pass it across and secure it to the opposite side with a slip knot.

Care must now be observed to press down with a straight edge the remaining springs in the row to the required height before securing the surplus end of the twine in front by tacks in the same manner as at the start. Continue with the next row and so on, then in like manner with each spring to the opposite end until the five rows are cross-tied. The springs for this purpose are what are used for sofa and couch work, and should be double-cone in shape, 8 in. high and the usual diameter of 6 in. A cover of cheap canvas, or low grade denim, or silesia may now be seamed and with ample margin, tacked over one side of the minor rail at the bottom and lightly stretched up and over the springs to the other side and down at the ends, thus making a

surface well calculated to receive the loose mattress.

Padding the ends may now begin, noting that the purpose will be to have mattress and padding press fairly together. The board *A* with the added cleat piece *B* is in the nature of a rough head board securely joining the two scroll ends, and is fastened to them in a diagonal manner, forming a solid foundation to build up in a conforming manner the upholstery filling consisting of part tow, curled hair and top layer of cotton. The open space between the head board *A* and the end rails is covered with tightly stretched canvas or upholstery webbing. This forms a surface to fill against with tow, hair and cotton, using a stout twine and an upholsterer's circular needle to hold it in place at frequent intervals, and using tacks and twine over the head board to hold it in place, meanwhile working and molding the material to the proper form full up to edges and end of scroll when a coarse piece of cotton cut to full size is tacked, starting from the inside of the end rail.

Before tacking the cover in place put the final layer of cotton over tow and hair, and pull the cloth upward, over and well under the end board *A*, pressing and molding with the hands. You will then know whether the material is to be added or removed before tacking down to a well-shaped roll.

The sides of cloth are now to be conformed neatly in a rounded manner and tacked against cleat *C*, provided for that purpose. Care in conforming this under-cover will make the work of putting on the outer cover a simple matter, edging it with a proper gimp and finishing nails.

The cover for outside of ends should be put over and under the cloth and finished with the same gimp and nails as on the inside.

Large well-filled pillow cushions will naturally be suggested later on in giving such a seat a broken outline and added comfort.

By the use of eight legs brought to a spade-shape foot as shown, and the upper part finished to a square of $1\frac{7}{8} \times 1\frac{7}{8}$ in., the frame of the bed will consist of an oblong frame $33 \times 75\frac{3}{4}$ in. The lower rail is 1 in. \times 2 in. \times $1\frac{1}{8}$ in., finished off flush with top of posts which set forward slightly. Rails may be treated with two grooved lines, or have a channeled effect as shown. Between the front and back intermediate legs there should be well secured cross bars, and on the lower inner edge of front and back rail, a well secured square support, partly notched out for slat spring support, *D*, which are $\frac{7}{8} \times 5$ in. wide. The upper scroll posts when prepared and treated in keeping with the lower rails and leg squares are then framed up with end rails and side rails *E*. The entire frame is then jointed off to a careful fitting and secured by glue and dowels to the lower bed. Reinforce on the inside with necessary glue and corner blocking and provide cleating for upholstery as explained.

As the frame is a simple treatment of the "Adam style" it is recommended in mahogany, birch, gum or walnut rather than in oak. The finish should be a dull rub, and let me remark right here that it's a good plan to use plenty of elbow grease.

Features of Armory Construction

Erecting the Drill Hall Frame and Placing the Concrete of a Modern Armory Building

ONE of the largest National Guard structures in the West is undoubtedly that of the Second Infantry Armory now rapidly nearing completion in Chicago, having a frontage of 236 ft. in West Madison Street, and extending through to Monroe Street, a distance of 266 ft. An alley leads through the center of the block parallel with West Madison Street, and in order to build across this alley it was necessary to supply alleys on both sides of the building from the center of the block to Monroe Street. This produced a T-shaped structure, the West Madison Street frontage of which is three stories and basement in height with a large central tower five stories high and a rear arched drill hall 300 ft. wide, 126 ft. long and 90 ft. high.

The building is of fireproof construction throughout with reinforced concrete foundation walls and floors, including the balcony, which extends around three sides of the drill hall. In the basement are twenty-eight shower baths, general toilets, wardrobe accommodations for 7000 people, boiler and fan rooms, wagon storage connected with the alley by a wide runway, also an up-to-date range for rifle and pistol practice for the men.

On the first floor are two field gun company rooms, quarters for the hospital corps, the band, the quartermaster's department, and twelve company rooms facing the drill hall. The second floor contains quarters for the medical examiner and various staff and commanding officers. On the third floor is a gymnasium, a banquet hall, shower baths, smoking rooms, kitchen, etc. The fourth floor has two signal corps rooms, and the fifth floor, storage and fan rooms.

Some of the construction features of greatest

interest to builders are undoubtedly the methods used in erecting the large arched frame for the drill hall and placing the concrete in the extensive area covered by the building.

The roof and balcony of the drill hall are carried by three hinge arches having a span of 198 ft. and a height of 89 ft. measured between the pins. They are spaced 37 ft. apart and are connected by deep latticed struts on which are carried the curved purlins which support the roof. In the course of erection the arches were assembled on the ground and completely riveted to make two building segments each about 120 ft. long. They were erected by a steel traveler 38 ft. square and 38 ft. high, on

which were mounted two 90-ft. booms. The heels of the segments were first lifted into the cast supporting shoes and the heel pins driven. Each boom was then attached to a segment near the crown pin and the two segments lifted simultaneously by rocking them back on the heel pin until the crown pin holes registered, thus permitting the crown pin to be driven. By this method the booms were required to lift only about one-fourth of the weight of the

Interior of Armory Building During Process of Construction

arch, the total weight of which was about 36 tons.

All of the immense amount of concrete required in connection with the building was mixed in two one-third yard "Standard" low charging mixers, made by The Standard Scale & Supply Co., Chicago, Ill. The materials for the concrete were delivered by motor trucks around the building near the points where it was to be used, and the mixers moved along as the work progressed, thus permitting a considerable quantity of the concrete to be spouted directly from the mixers into the "forms," and when delivering in carts it was necessary to

wheel the concrete only a short distance. The portability of the mixers also enabled them to be moved several times during the progress of the work by simply picking them up bodily by the travelers and carrying to a position where it was desired to mix additional concrete. When laying concrete for the floor of the drill hall the same method was pursued, thus rendering it unnecessary to wheel any of the materials a long distance.

For placing the concrete in the balcony the mixer was stationed near the center of the drill hall and equipped with concrete tower and spout. The latter was suspended from the steel frame of the drill hall, as shown in the picture, so that it delivered concrete to a bin on an elevated platform, from which it was gated into wheelbarrows for distribution. The reader will readily note that the economy of a large part of this construction work was obtained in a measure through the portability of the mixers used, as this afforded a great saving in the amount of manual labor required both in delivering the material to the mixers and the concrete to the forms.

The plans of the armory were prepared by State Architect James B. Dibelka, and the general contract was executed by C. E. Carson Co., City Hall Square Building, Chicago, Ill.

Building in Manhattan in March

According to the Bureau of Buildings for Manhattan, New York, plans were filed in March for 46 new structures, costing \$5,262,800, as compared with 47 costing \$4,134,025 in March, 1915.

Among the more important improvements for which permits were issued in March were a \$400,000 addition to the Hotel Apthorpe at Broadway and Ninety-fourth Street; a \$450,000 four-story students' building for Barnard College, on Claremont Avenue, just above 116th Street; a \$600,000 duplex studio apartment building, fifteen stories high, at Central Park West and Sixty-seventh Street; a \$350,000 five-story power plant, corner of Water Street and Burling Slip; a \$150,000 six-story showroom and loft buildings on Thirty-third Street, adjoining the Astor Court Building; a \$300,000 twelve-story loft at 104 to 110 Green Street; two five-story flats at 138 to 150 Haven Avenue, to cost \$200,000; a six-story telephone exchange, corner of Manhattan Avenue and 108th Street; a \$100,000 twelve-story office building on Cortlandt Street, west of Broadway; a \$170,000 twelve-story building for the Lenox School on East Seventy-eighth Street and East Seventy-seventh Street; an \$80,000 six-story dwelling for Harris Fahnestock on Sixty-sixth Street, west of Madison Avenue; a \$250,000 twelve-story factory building on Thirty-eighth Street, east of Sixth Avenue; a \$225,000 six-story factory, corner of Frankfort and Rose Streets; a \$140,000 twelve-story loft, adjoining Lord & Taylor, on Thirty-ninth Street, west of Fifth Avenue; a \$100,000 six-story warehouse on Sixtieth Street, east of Broadway; a \$140,000 six-story flat at 341 to 347 West Forty-fifth Street, and a \$150,000 twelve-story loft on Thirty-eighth Street.

Brooklyn, N. Y., is contemplating a public library for the Prospect Park Plaza which will cost in the neighborhood of \$600,000.

Building Trades Wages for 1916

We have received from Roswell D. Tompkins, secretary of the United Board of Business Agents of the Building Trades of the Borough of Manhattan and vicinity, New York, the prevailing rate of wages in various branches of the building trades for 1915. This schedule is based on 8 hr. work per day, except on Saturday, when work in the building trades ceases at noon.

•Asbestos workers, boiler felters, pipe coverers, insulators	\$4.75
•Asbestos workers' helpers	3.00
Blue stone cutters, flaggers, bridge and curb setters	4.50
Blue stone cutters' helpers	3.00
Bricklayers	6.00
Bricklayers' helpers	3.00
•Carpenters and framers	5.00
•Cabinet makers	5.00
•Cement and concrete masons	5.00
•Cement, concrete and asphalt laborers	3.00
Derrickmen and riggers	4.00
•Decorators and gilders	4.50
Decorative art glass workers	5.00
Elevator constructors	5.25
Elevator constructors' helpers	3.40
•Electrical workers	4.80
•Electricians' helpers	2.20
•Electrical fixture workers	4.80
Engineers, stationary	4.50
Engineers, portable hoisting, etc. \$30.25 weekly; by the day	6.00
Engineers on boilers, pumps or pile driving machines	\$30.00 weekly
Engineers on all excavating, broken time by the day	\$6.00
•Framers	\$30.00 weekly
Granite cutters	5.00
Glaziers	3.50
House shorers, movers and sheath pilers	3.75
House shorers' helpers	2.65
Housesmiths, bridgemen and structural ironworkers	5.30
•Ironworkers, bronze, metal furniture and metal trim workers	5.30
•Ironworkers' helpers	3.50
Ironworkers' apprentices	3.00
Metallic lathers	5.50
Marble cutters and setters	5.50
Marble carvers	6.00
Marble polishers	4.40
Marble sawyers	4.65
Marble bed rubbers	4.95
Marble cutters' helpers	3.25
Rigging and crane operators	3.75
•Mosaic workers	4.50
•Mosaic workers' helpers	3.00
Machine stone workers	4.50
Machinists of all description	5.50
•Paper hangers	Price list
Plate and sheet glass glaziers	3.50
Plasterers, plain and ornamental	6.00
Plasterer modelers	\$30.00 to \$100.00 weekly
Plasterers' helpers (after May 1, \$3.50)	3.25
•Plumbers and gas fitters	5.50
•Painters	4.00
•Painter-decorator, painter-striper, painter-gilder	4.50
•Painter-letterer, painter-grainer	4.50
Riggers on machinery, dynamos, boilers, etc.	4.00
•Roofers, tar, felt, composition, damp and waterproofers	4.25
Rockmen and excavators	2.80
Rock drillers and tool sharpeners, open work, \$3.68; tunnel	3.75
Sheet metal workers, coppersmiths, tinsmiths, metal roofers	5.00
Slate and tile roofers	5.50
Steam, hot water and general pipe fitters	5.50
Steam fitters' helpers	3.00
Tile layers (after Jan. 1, 1917, \$6.00)	5.50
Tile layers' helpers	3.25
•Varnishers	4.00
Wood lathers	6.40
Wood carvers and modelers	5.00

*Subject to change.

Compensation for a practical foreman ranges from fifty cents to one dollar per day over and above schedule as shown. All recognized legal holidays and Sundays to be figured at "double time."

Buildings for San Francisco Presidio

Plans have just been received at San Francisco Army headquarters for twenty sets of new quarters for line and field officers, to be built on the Presidio reservation, west of the Exposition grounds. The new quarters will be strictly fireproof, provision being made for either concrete, tile or brick construction. Attention was called forcibly to the need for better buildings at the Presidio several months ago, when a fire in one of the old officers' homes caused the death of the family of a General.

New Publications

House Wiring. By Thomas W. Poppe. 125 pages. Size 4 x 7 in. Illustrated with Original Engravings. Bound in flexible cloth. Published by Norman W. Henley Publishing Co. Price 50c.

This is a practical little work of handy pocket size, now in its second edition. It is primarily intended for persons who are desirous of obtaining a practical knowledge of the installation of electric lighting systems, and the matter is presented in a clear, non-technical manner. The examples are of a practical nature, the author aiming to convey his knowledge in as few words as possible consistent with clarity. The work treats of the wiring of both finished and unfinished buildings, showing the three- and four-way circuits. Bell and annunciator wiring, burglar alarms and appliances constitute separate chapters in connection with which wet and dry batteries are treated. Interesting information is presented concerning the several conduit systems, plans and layout of electrical work, wiring and switch diagrams, etc. The installations described are in accordance with the rulings of the National Board of Fire Underwriters.

The Law of Architecture and Building. By Clinton H. Blake, Jr. 314 pages. Size 6 x 9 in. Bound in law canvas. Published by the William T. Comstock Co. Price \$3.00.

The architect many know how to design a building and the builder may know how to erect it, but when it is necessary for either one of them to know just what are his rights, he is more or less at a disadvantage as to the methods of procedure. Many an architect and builder has suffered monetary loss because of ignorance of his rights and the uncertainty of his case often impels him to submit for fear of becoming worse involved. The work under review is intended to show the exact status of the builder in relation to the architect, the architect in relation to the builder, and the relation of both to the owner, together with the extent of the liabilities of each. A number of actual cases and standard legal forms and contracts contribute to a complete, yet simple, exposition of the laws governing contractors and architects.

Handwork in Wood. By William Noyes. 231 pages. Size 6 x 9 in. 304 illustrations. Bound in cloth. Published by the Manual Arts Press. Price \$2.00.

This book, now in its fifth edition, is by a member of the faculty of Teachers College, Columbia University, and is intended primarily for teachers of woodwork, the author's experience well fitting him to make his ideas of interest to instructors. Professional and amateur workers in wood will also find much within its covers to clear up many points which may have been somewhat obscure to them. The story of the log is well told, the author taking his readers through the details of logging, then giving them a glimpse of the saw-mill and ends up his preliminary three chapters

with a section devoted to seasoning. He then devotes about seventy-five pages to the uses of various kinds of hand tools for working wood.

The latter part of the book is devoted to explanations of "Wood Fastenings," "Common Joints," "Types of Wooden Structure," "Principles of Joinery," "Wood Finishing," etc.

Well executed photographic views and drawings illustrate the stages of construction and the necessary machinery to turn the raw log into a highly finished product.

The Book of Thrift. By T. D. MacGregor. 349 pages. Size 5 x 7 $\frac{1}{2}$ in. Bound in cloth. Published by Funk & Wagnalls Co. Price \$2.00.

There are many books written on how to make and save money, but very few touch on the subject of thrift. The author explains just what thrift is and tells of the enormous waste of the vast resources of our country. He shows how this waste is carried into the homes and business of the majority of our population.

The ambitious young carpenter or builder may learn from this work many a practical hint which perhaps may be just the idea needed to turn the balance in his favor. He is told how to secure a desired education and how to start in business. It is pointed out to him how to secure the capital and credit for his business career: how to keep his money after he has made it, and indeed, the careful reader will find a helpful array of inspiring information which may well prove to be of practical money value to him.

Wiring of Finished Buildings. By Terrell Croft. 275 pages. Size 5 $\frac{1}{2}$ x 8 $\frac{1}{2}$ in. Illustrated with 205 diagrams, etc. Bound in cloth. Published by McGraw-Hill Book Co., Inc. Price \$2.00.

It has been estimated that only 8 per cent of the houses in this country have been wired for electricity, naturally, the bulk of the wiring has been done in the larger cities, while the country sections have been sadly neglected. In many localities there is no electrician handy and the builder is often called upon to do the work or at least superintend its installation. Even if not desirous of doing the work himself, he naturally wants to be sufficiently familiar with the subject of house wiring to arrange the details, so as to enable the wiring to be easily and efficiently done. The book is a practical treatise on the subject indicated by the title. Methods of wiring, the planning of installations, the necessary tools and their uses and fixtures are described so that the builder can make a good job if he is called upon to do the work.

The general contract for the erection of the 1000-room hotel which the Pennsylvania Railroad is about erecting on the Seventh Avenue block-front, facing its terminal, New York City, has been secured by the George A. Fuller Company. The plans are being prepared by McKim, Mead & White, the well-known architects of the city.

Brief Review of the Building Situation

Building Operations for March in 126 Cities Show
an Increase of 15.27 Per Cent Over March, 1915

NEW construction work at the present time is making comparison with a period a year ago when the country was emerging from the extreme depression growing out of the European War, and the gain therefore for March, 1916, is not as striking as were the two previous months, although reports at hand from 126 cities show building operations to be larger by 15.27 per cent than they were in March, 1915.

Taking the Eastern section of the country, from which reports are at hand from forty-seven cities, there are thirty showing a decrease and seventeen an increase as compared with March last year, with a resultant gain of 4.6 per cent. The accompanying table shows the relative activity prevailing in the various cities.

CITIES OF EASTERN STATES

	March, 1916	March, 1915
Albany	\$199,090	\$342,855
Allentown	100,310	127,780
Altoona	21,999	68,528
Bayonne	42,440	39,747
Binghamton	179,939	138,878
Boston	3,967,000	4,719,000
Brockton	44,285	186,008
Buffalo	899,000	830,000
East Orange	60,018	86,732
Elizabeth	118,723	96,502
Erie	218,799	296,966
Harrisburg	158,668	152,750
Hartford	853,305	706,237
Haverhill	25,700	87,250
Hoboken	6,036	47,450
Holyoke	118,950	24,675
Irvington	56,894	79,360
Jersey City	333,123	657,135
Lawrence	300,405	288,880
Manchester	105,605	83,080
Montclair	51,702	106,828
Newark	783,790	643,392
New Bedford	495,625	587,775
New Haven	520,560	825,470
New York:		
Manhattan	8,580,439	4,965,380

Portland, Me.	110,525	161,750
Reading	48,925	164,350
Rochester	596,243	1,000,000
Schenectady	61,860	81,336
Scranton	40,490	102,124
Springfield	560,568	570,588
Syracuse	177,745	520,533
Trenton	235,504	192,868
Troy	35,375	68,106
Utica	37,925	94,855
Wilkes-Barre	173,255	257,752
Worcester	780,130	353,360

From the middle section of the country reports from thirty-eight cities show an increase over March last year of 18.14 per cent, construction work being especially active in Chicago, Detroit, Kansas City, St. Louis, St. Paul, Sioux City and Toledo, while some of the more important cities reporting a shrinkage in new work planned are Cincinnati, Cleveland and Milwaukee.

CITIES IN MIDDLE STATES

	March, 1916	March, 1915
Akron	\$524,715	\$437,605
Cedar Rapids	95,000	152,000
Canton	529,200	189,250
Chicago	11,477,100	7,403,750
Cincinnati	948,500	1,356,124
Cleveland	1,838,465	4,022,035
Columbus	868,938	519,200
Davenport	96,084	73,865
Dayton	356,240	112,465
Des Moines	400,144	119,365
Detroit	3,677,785	2,839,490
Duluth	237,595	159,125
East St. Louis	30,292	80,955
Evansville	139,490	402,327
Fort Wayne	115,425	254,290

CITIES IN MIDDLE STATES (Continued)

	March, 1916	March, 1915
Grand Rapids	617,020	260,429
Indianapolis	906,268	889,349
Kansas City, Mo.	1,226,619	848,595
Kansas City, Kan.	55,460	165,285
Lima	216,925	150,325
Lincoln	153,040	97,450
Milwaukee	690,798	942,921
Omaha	346,805	332,860
Peoria	151,170	159,175
Quincy	87,695	185,402
Saginaw	10,940	81,215
St. Joseph	214,303	50,903
St. Louis	1,761,781	1,268,878
St. Paul	1,064,452	822,624
Sioux City	552,680	167,675
South Bend	12,529	43,547
Springfield	670,785	88,920
Superior, Wis.	18,255	67,235
Terre Haute	48,235	57,535
Toledo	1,022,495	763,258
Topeka	51,440	73,500
Wichita, Kan.	145,950	27,900
Youngstown	176,313	148,295

In the Southern section of the country the increased activity as compared with March last year is especially noticeable, twenty-four cities reporting show eighteen increases and six decreases with a resultant gain of 38.16 per cent. This is due in large measure to the greater amount of work planned in Atlanta, Baltimore, Dallas (Tex.), Nashville, Norfolk (Va.), Richmond and Washington.

CITIES IN SOUTHERN STATES

	March, 1916	March, 1915
Atlanta	\$458,401	\$267,417
Baltimore	1,305,111	882,701
Birmingham	188,426	154,555
Chattanooga	184,015	40,865
Corpus Christi	18,625	17,423
Dallas, Tex.	452,891	147,690
Fort Worth	202,992	125,930
Huntington	68,975	390,800
Jacksonville	66,100	259,500
Louisville	576,730	518,100
Macon	42,968	84,351
Memphis	306,060	345,785
Miami	96,700	89,200
Montgomery	47,849	11,765
Nashville	352,884	190,570
New Orleans	248,936	194,385
Norfolk, Va.	1,276,139	180,694
Richmond	593,720	284,826
Savannah	57,300	132,700
San Antonio	199,470	95,500
Shreveport	62,570	47,479
Tampa	116,245	116,387
Washington	1,579,301	714,826
Winston Salem	171,000	70,452

Coming now to the extreme Western section of the country, and including territory west of Denver, the volume of building operations is 28.19 per cent as compared with March a year ago. The increased activity was especially noticeable in Los Angeles, Oakland, Pasadena, San Francisco, Seattle and Spokane.

CITIES IN EXTREME WESTERN STATES

	March, 1916	March, 1915
Berkeley, Cal.	\$160,000	\$140,950
Colorado Springs	27,617	22,700
Denver	386,390	181,130
Los Angeles	1,416,535	1,124,063
Oakland	910,680	500,373
Pasadena	175,132	79,373
Portland, Ore.	420,560	503,755
Pueblo	40,454	8,360
Sacramento	109,497	148,725
Salt Lake City	314,550	209,385
San Diego	203,312	94,685
San Francisco	2,512,328	1,405,038
San Jose	53,635	97,971
Seattle	735,785	689,675
Spokane	246,059	102,660
Stockton	88,325	140,814
Tacoma	168,122	192,450

For the first quarter of the present year the increase over the corresponding three months of last year is most encouraging, and the outlook for 1916 is at least for an average amount of construction work.

Fiberlic Wall Board

*“All
the
Fibre
In
Fiberlic”*

DEWITT CLINTON POND, M.A., of Columbia University, well and truly states that it is the architect's "duty to know enough about all the things that are required to make a complete building in order to properly protect his client." This applies not only to the architect, but to the contractor, carpenter and builder as well. Comparative tests made by disinterested authorities have determined that FIBERLIC WALL BOARD is superior in bursting strength, tensile strength, shear and compression, as well as limit of elasticity—and why? Because it is made from a chemical fibre and is not like a wall board made from a mechanical pulp that is short fibred and filled with starch and other vegetable matter that will harbor mould growth.

You Have “All the Fibre in Fiberlic”

FIBERLIC is thoroughly Vermin-proof and Sanitary, and, therefore, it is being used in the Home, Hospitals, Doctors' Offices, Stores, Business Offices, Theatres, etc.

FIBERLIC is thoroughly sized throughout.

FIBERLIC Wall Board is the only Patented, Chemically Treated, Long-fibred Board manufactured.

FIBERLIC is Fire Resisting.

There is no Unpleasant Odor about Fiberlic. This means something to the Home Builder.

Write for samples. All Fiberlic samples are cut from stock and the board that we ship is absolutely the same as our samples.

THE FIBERLIC COMPANY, CAMDEN, N. J.

LONDON (England) BRANCH: MacAndrews & Forbes, Ltd., Finsbury Court, E. C.

This ROOFING CATALOG

(The Largest and Most Complete Ever Printed)

WILL HELP YOU

The *Rex Products* catalog contains 112 pages and more than 180 pictures and illustrations. Besides complete instructions for laying all styles of asphalt shingles and prepared roofings, you will find in it a full description of each one of the 27 different *Rex Products* which we manufacture. You will also find much helpful information about slate, tile, asbestos shingles, tin and corrugated steel roofings.

We will send you this splendid catalog and a set of samples without cost or obligation to you. Write—

Flintkote Manufacturing Co.

98 Pearl St., Boston, Mass.

1104 Equitable Bldg., New York, N. Y.

651 Peoples Gas Bldg., Chicago, Ill.

Hennen Bldg., New Orleans, La.

REX STRIP SHINGLES

Will not blow up in the wind because the spaces between the shingles do not extend under the shingles in the course above, and so there is no opening for the wind to get under them and lift them. This is why Rex Strip Shingles make a *tighter* roof than any individual shingles.

REX STRIP SHINGLES
ARE ONLY ONE OF THE
REX PRODUCTS
DESCRIBED IN THIS CATALOG

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Important Purchase of Metal Lath Interests

Under the above title we presented in our last issue brief announcement of the fact that the Sykes Metal Lath and Roofing Company, Warren, Ohio, had purchased the metal lath department of the Brier Hill Steel Company at Youngstown, Ohio, which was formerly operated under the name of the Garry Iron and Steel Company, Niles, Ohio. Supplementing this announcement we learn that the increased demand for Sykes ex-

Fig. 1—Horizontal Section of Wall or Partition Showing Use of Sykes Expanded Cup Lath

panded cup lath "self-furring," has compelled the company to make arrangements for materially increasing its manufacturing equipment and it is firmly believed that with the Garry plant it will be able to give its customers better service as well as the benefit of a very complete line of metal lath. The company is now able to furnish the following:

- "A" grade Cleveland Expanded Metal Lath
- "B" grade Cleveland Expanded Metal Lath
- Garry Metal Lath
- Diamond Mesh Metal Lath
- Sykes Expanded Cup Lath "Self-Furring"
- Sykes Trough Sheet Lath

In addition to the above the company will turn out corner bead, wall ties, etc., and place itself in a position to promptly meet the wants of its rapidly increasing trade. In Fig. 1 we present a cross-section of a plastered wall or partition showing the use of Sykes expanded cup lath which is said to give greater durability by giving more weight. By its peculiar formation it reinforces the wall, as clearly indicated in the cut, and "becomes a firmly imbedded backbone of strength."

Architects' Specifications for Carey Building Materials

An attractive publication bearing the above title has been prepared for distribution among architects and builders by the Philip Carey Co., 1020 Wayne Avenue, Lockland, Cincinnati, Ohio. An interesting feature in connection with it is the statement that it has been compiled in conformity with the specifications of the American Institute of Architects and is therefore a valuable reference book for architects, engineers, contractors and prospective builders. The several Carey products are illustrated and instructions given for applying them. Reference is made to Carey Flexible Cement Roofing, which is built of a foundation of wool felt with a heavy body of asphalt cement above; Carey Asfaltslate Shingles, built on a base of heavy wool felt, saturated and coated with a waterproof asphalt compound, and finished with a heavy coating of crushed slate in permanent natural colors, red or green; Carey Ceil-Board, made of three sheets of chip stock bound together with Gilsonite asphalt cement and sized on both surfaces of the finished board with paraffine and furnished in six different finishes; Carey Rubber Roofings, having the surfacing materials embedded in the

asphalt top coating while it is still hot, and the sheets then put through heavy rollers; Carey Elastite, used in concrete walls, piers, sidewalks and all construction work where it is necessary to provide for expansion of materials; Carey Fibrewove Insulating Paper, used as a paper lining for buildings, and said to be moisture-proof, vermin-proof, acid-proof, decay-proof, temperature retarding and odorless, and Carey Percoproof, a damp-proofing compound made of a fusion of water-proof gums worked into a uniform mass without pores. Carey Magnesia and Asbestos Insulating Products, as given in the catalog, constitute a basis for the proper class of insulation to be used for certain fundamental conditions. The engineering department of the company is ready to give any assistance possible in the solving of insulating problems.

Change of Name of Sandusky Portland Cement Co.

The corporate title of The Sandusky Portland Cement Company, Cleveland, Ohio, has recently been changed to that of "The Sandusky Cement Company," the officers and directors in the new company being the same as those of the old concern. There will be no other changes of any kind whatever, the business of the company being carried on as formerly, but the trade is requested to make special note of the new title and make use of the same in all correspondence.

The "Grand" Concrete and Mortar Mixer

There are many building contractors who, having occasion to make use of both a concrete and mortar mixer, but whose work will not always justify the purchase of two separate machines, are likely to be interested in the combination machine illustrated in Fig. 2, which is particularly adapted to meeting their

Fig. 2—General View of the "Grand" Concrete and Mortar Mixer

requirements. The combination machine which is being offered under the name "Grand," has a capacity when operated as a concrete mixer of 7 to 8 cu. yd. of concrete per hour, and when operated as a mortar mixer will supply from forty to fifty masons. The construction is such that the machine can be quickly changed to mix either concrete or mortar, according to requirements. The "Grand" mixer is rigidly built, is mounted

upon steel wheels 20 x 30 in. in diameter, with 3½-in. thread, and is readily portable. The mixing trough contains twenty-six paddles, one-half of which are set at reverse angles in order to insure thorough mixing and tempering. The discharge end of the mixing trough is equipped with a self-locking grate that holds the mortar until it is thoroughly mixed. The machine is equipped with high-grade tub top and water-cooled 4-hp. gasoline engine, which it is claimed is ample to operate it at its maximum capacity. The combination mixer here shown is made by the Hall-Holmes Mfg. Co., Jackson, Mich., which has issued an attractive folder relating to the machine and a copy of which can be obtained by any reader of THE BUILDING AGE upon application to the address given.

Berger's Exhibit at Complete Building Show

We take pleasure in presenting herewith a photographic reproduction of the display made at the recent Complete Building Show in Cleveland by the Berger Mfg. Co., Canton, Ohio. This exhibit was unusually interesting and instructive inasmuch as it showed the company's various products installed in a practical way,

agement of the Complete Building Show. In the rear of the booth is shown an I-joint used in the fire, load and water test made by Columbia University, New York City, some time ago for the benefit of the Building Bureaus of the city.

Ransome Mixer Company, Inc.

A. W. Ransome, for fourteen years vice president and general manager of the Ransome Concrete Machinery Company of Dunellen, N. J., having severed his connection with the latter company, has organized the Ransome Mixer Company, Inc., with headquarters at 35 West Thirty-ninth Street, New York. This company will manufacture a line of concrete mixers and will also handle a line of contractors' machinery as well as the Insley Line of Gravity Plants.

Reynolds Shingle Bulletin

In the March issue of the "Bulletin" of the H. M. Reynolds Asphalt Shingle Co., Grand Rapids, Mich., there is a most interesting article on "The Felt Situation," which explains, among other things, the reason

Fig. 3—Photographic View of Exhibit of Berger Mfg. Co. at Recent Complete Building Show in Cleveland

thus enabling architects, builders, contractors, engineers and others to readily understand their uses and applications. Referring to the picture, Fig. 3, it will be seen that in the foreground at the left is displayed Berger's metal lath attached to metal lumber studs and partially plastered; also Berger's "Raydiant" sidewalk and vault light construction, clearly indicating the form used as a base, the reinforcing rods and the malleable-coated Tanex glass. One-half of it is cemented to show a finished installation and the other half the detail of construction. In the foreground at the right are shown Berger's metal lath, corner beads, and base screed. The corner beads, as is well known, are used to protect corners of plastered walls from cracking, chipping and breaking, while the base screed offers a permanent ground for the plaster above and the cement base below. Directly above these products are Berger's pressed steel cores for displacing concrete and forming concrete joists for long spans in light or heavy construction; rib-truss and ferro-lithic reinforcing plates used for floors, roofs, partitions and side walls for all classes of buildings. In the background of the picture is shown the metal lumber floor construction which was used in the first floor of the \$6000 prize house given away by the man-

for the increasing cost of asphalt shingles. "The foundation of the roofing material," it states, "was at first an experimental problem. Papers of various kinds were tried out but they were soon discarded because it was found impossible to properly saturate them. After a long series of experiments, manufacturers adopted a felt made of rags as being best suited to their demands. The rag felt possessed greater tensile strength and absorption properties, the real merit of asphalt roofing depending upon proper felt saturation so that it might be thoroughly impervious to water. No substitute has been found for felt, so that increased felt-cost necessarily means increased shingle-cost. The war has shut off about 40 per cent of the rag supply and an increased demand, due to the substitution of felt for burlap, has made the price of felt increase from about \$45 at the beginning of 1915 to a March, 1916, quotation of \$85 per ton, delivered at the factory. This means an increased manufacturing cost of 80 cents per square for asphalt shingles in a year's time." The Bulletin is illustrated with halftones showing Reynolds shingles in use on various houses and garages. It is stated that exhaustive tests have been made with Reynolds shingles

"These Are The
Bath Room Fixtures
We Want"

A book all builders
should have

In addition to being a catalog of KOHLER Enameled Plumbing Fixtures, this book, "KOHLER of KOHLER," contains an interesting description of the KOHLER factory and the processes of KOHLER production.

It explains how we maintain one grade of KOHLER quality, which is the highest.

It tells you how we have made enameling one of the finer arts.

KOHLER

a trade-mark
that means excellence
in plumbing ware

The name KOHLER, permanent in the enamel of each of our products, is accepted everywhere as evidence of the highest quality.

It is our guarantee of high-grade material and workmanship and the purchaser's safe guide in the selection of modern hygienic plumbing ware.

The "Viceroy," our latest built-in bath, is an exceptionally attractive fixture.

It is made in *one piece*, is enameled all over, can be installed with or without tiling and is low in price, due to manufacturing economies. This beautiful tub is fully described in "KOHLER of KOHLER." Write today for a free copy.

by the Board of Fire Insurance Underwriters, the result being that the Board has rated the shingles in the same classification as slate or tile.

Empire Pipeless System of House Warming

Much attention is at present being given to the subject of pipeless house warming, and the heater shown in broken view in Fig. 4 is therefore likely to interest many of our readers. It is known as the "Empire Pipeless Furnace," and is so constructed that it may be set up in high or low cellars as may be preferred. A combination duplex grating register is placed in the room directly over the heater, this being the only register required. The furnace has two casings of heavy galvanized steel, the inner one being thoroughly insulated with heavy sheet iron and asbestos paper. The cold air from the room passes into the outer section of the register, continuing down through the opening between the inner and outer casing, and then under the inner casing, where it comes in contact with the heat from the furnace. As it becomes warmed it rises and passes out into the room through the round opening in the center of the register. This means a constant flow of air through the rooms, due to the fact that warm air rises and cold air falls. It is claimed that all floors are maintained at a nearly uniform

Fig. 4—Broken View of the "Empire" Pipeless Heater

temperature throughout the house. The Co-operative Foundry Co., Rochester, N. Y., states that the double casing keeps the cellar cool, the outer casing being kept chilled by the descending cold air. The fuel may be hard or soft coal, wood or natural gas, the company furnishing gas rings when desired. Other features are an unusually deep and roomy ash pit, deep cup joints, thoroughly cemented and gas tight, and grate so made that each bar of it can be taken out separately. The fire pot is either one-piece or two-piece, and is heavy and ribbed. There are hot water connections and a feed door of ample size. The patterns are claimed to be perfectly fitted, consequently when setting up the furnace no difficulty is experienced in mounting the different sections into a perfect, gas-tight heater.

Garage Door Equipment

An interesting catalog bearing the above title and sent out by the Richards-Wilcox Mfg. Co., Aurora, Ill., contains two instructive articles giving the solution of problems which may have often puzzled the architect or builder. These are entitled "The Garage Door Problem" and "Locking Garage Doors." The first treats especially of the use of sliding doors in the small one-car garages which are so popular. No matter how large the door opening may be in proportion to the building, a sliding door, it is stated, can be satisfactorily fitted. The solution is simple, consisting of an arrangement of

5000 Building Bargain Book—156 Pages FREE!

TO CONTRACTORS AND BUILDERS!

SEND us the coupon today. We want to place this great illustrated book in the hands of every contractor in America. We want to send it to you. Thousands of the most successful contractors and carpenters, expert judges of values, keep our great catalog and valuable books on hand to guide them in buying and estimating.

Ten thousand contractors and carpenters buy practically all their building materials, lumber, hardware, paints and the like of us. We offer you the same wholesale-to-builder prices, the same extra quick delivery.

Our stocks are so complete, always, that no building job is ever held up because of a delay on a few items. We carry in stock hundreds and hundreds of bargains that can be bought elsewhere only on special order at high prices.

The facts are that the Gordon-Van Tine Co., offers the biggest, broadest, finest stock of quality building material on earth. Quality for quality our prices are the lowest. Our guarantee assures you of satisfaction or your money back. We ship to you anywhere!

Galesburg, Illinois
October 15, 1915
Gordon-Van Tine Company,
Davenport, Iowa

Dear Sirs:—

I am taking a breath at the height of a busy fall building season to thank you for the fine way in which you have gotten my material to me. My success this season owes a great deal to the promptness with which you got my material on the job and the uniformly high quality of everything sent me.

In thanking you in this way, I merely wish to tell you that I appreciate being treated right and that is certainly what you have done throughout. An occasional error or an occasional delay would creep in now and then, but I will say that you people never hesitated to correct these things regardless of trouble or expense.

Indications are that the coming spring will be a big one in this vicinity and I am looking forward to being again helped by your prompt deliveries and dependable material. If we continue to work together as we have in the past, I am sure that it will pay us both.

Accept my kindest regards.

Yours very truly,

Signed

E. H. KEGLEY

Doors

All styles and sizes. Quality guaranteed. Hundreds of special designs ready for immediate shipment. See pages 12 to 19 in Catalog. As low as \$1.07.

Windows

Why Have Heating Pipes in Your Partitions?

Now that you come to think of it, heating pipes are an awful hitch on construction work, aren't they?

But you don't *have* to hold up your mason and paper-hanger until the furnace man gets on the job. You don't *have* to take a chance of over-running the contract!

You can disregard the furnace proposition entirely until the house is completed. The Empire Pipeless Furnace does away with all partition work. May we tell you how it works?

"R-W Trolley Right Angle Door Hangers" so disposed as to allow the jamb side of the door to swing along the inside of the garage wall until the other side comes flush against the wall. The door is then flat against the side wall at right angles to its position when closed. Altogether, twenty-five different door schemes are presented accompanied by twenty-eight explanatory illustrations. The second article aims to show how all door-locking problems can be solved, eighteen illustrations picturing the various methods. Prices, sizes, etc., of these doors and locks are contained elsewhere in the catalog. There is also described an "R-W Stewart Electric Door Opener and Closer," which consists of a three-button system—one button to open the door, another button to close it and a third button to stop the door at any desired place. The control buttons can be put in any part of the building, the whole system being readily installed by any electrician.

Modern Equipment an Important Factor of a Contractor's Success

Much might be said regarding the value of modern equipment to the contractor and builder who undertakes a wide variety of work in town and country, and the matter may possibly be summed up as follows: First, that it enables the contractor to undertake certain work that would otherwise have to be refused if up-to-date machinery were not used; secondly, that the purchase of good, substantial machinery is an investment that will produce dividends in the reduction of construction costs, the progress of the work may be facilitated, insuring the owner of a first class building that will stand

Fig. 5—Building Operation Showing Oshkosh Concrete Mixer at Work

as a monument to the contractor's ability and pave the way to more profitable business relations with the architect and owner. An exceptionally interesting instance of a progressive contractor and builder who does an annual business approximating \$75,000 in a town of 50,000 population and vicinity is demonstrated in the experiences of the Du Boise Construction Company of Flint, Mich. Much of Mr. Du Boise's success can be traced to his foresightedness in purchasing the necessary equipment that has enabled him to carry to a successful conclusion contracts for all classes of structures. Mr. Du Boise uses a concrete mixer of a type made by the Oshkosh Mfg. Co., Oshkosh, Wis., as well as one of the same company's saw tables, several derricks made by the Sasgen Derrick Co., Chicago, Ill., an automatic pump for foundation work and other equipment. The president of this company was recently interviewed by a representative of THE BUILDING AGE, at which time he volunteered the following remarks:

"I can safely say that modern equipment has contributed much to the success of the Du Boise Construction Company. In recent years we have erected churches, schools, warehouses, hospitals and a variety of buildings that we felt confident we could execute to the owner's satisfaction at a reasonable figure. In regard to our mixer, the past two years has demonstrated its efficiency to such an extent that we find it indispensable. It has a daily capacity of about 80 cu. yds. when running, as near as possible, on a mix-a-minute basis. This enables us to go right ahead with the work and keep the men busy and is the means of facilitating

Ever Get Stung?

with a furnace? Did the man tell you his was the only, only, **best** furnace—that it would heat you up to 80 in 40 below zero weather—on three tons a winter—and did he separate you from your dollars before you had a chance to test it; and then didn't you wish you had your money back?

We won't sting you. We don't want your money till you are satisfied with your furnace, **after a test.**

Here Are the Terms:

We will ship you a furnace, with all pipes, registers, etc., made to fit your house, first submitting complete plan for your approval. We will **prepay freight charges** to your station.

When the outfit arrives, check it up and pay your local banker the purchase price. He will hold it till **January first** subject to your test. You set up the equipment and use it and test it till that time. If it doesn't work

The HESS Welded Steel Pipeless Furnace. No horizontal pipes nor air ducts in cellar.

according to our guarantee—if you think it isn't worth our price—or more—send it back (we pay freight both ways) and the banker will return your money. We send full plan and directions for setting, also all tools, if you need them.

There's no trick about this offer. It has been in force for years, and it means just a **square, straight deal**, direct between maker and user.

We make a splendid furnace—welded steel—gas and dust tight, economical, simple and all that. For separate pipes or the new **Pipeless** sort. We describe it fully in a 48-page book which we send free. Ask for one, and read it, before you buy anything else in this line. You'll buy comfort and save money.

Special terms to contractors.

Here's a PORTABLE Closet
Saves You Big Money
on Every Job

Whether you're figuring on a building, on road construction, excavation, sewer or any other job—you can underbid competition every time and still make a better profit, if you own a

Kaustine
Portable Closet

Figure the big saving yourself: Every man wastes 10 minutes twice daily going to and from the inaccessible closet—that's 20 minutes daily, 8½ hours monthly (520 minutes); 20 men 2 months on a job lose 340 hours, and even at 25¢ per hour the waste of your money amounts to \$85. On jobs requiring more men and more time your loss is proportionately bigger.

The Kaustine Portable Closet is always accessible, does away with the big loss of time. Keeps your men in better condition, because they won't delay relief. (Those delays make men sluggish—result in slower and inferior work.)

Kaustine, the powerful germ-killing chemical, keeps this system sanitary, healthy, clean and neat. Initial cost is low, upkeep low.

Write for full particulars, and state number of men employed.

Kaustine Co., Inc., Dept. B-1 Buffalo, N. Y.

Also C. P. R. Building, Toronto, Ont.

the progress of the work. In other words, the work reflects considerable credit on the concrete mixer. Not long ago we found it imperative to do some foundation work when the temperature was about 10 deg. below zero. It was for a large warehouse, and specifications called for a 14-ft. basement with an 18-in. wall. We poured the concrete at a temperature of .65 deg. and the work was completed inside of three days. The concrete was afterwards tested and found in satisfactory condition. We have just completed the building of a concrete oil tank vault as shown in Fig. 5. It has dimensions of 30 ft. long, 22 ft. wide and 14 ft. deep, being sufficiently large enough to accommodate two steel tanks that have a combined capacity to hold three cars of oil. The vault has a bottom that is 14 in. thick and will be covered by a reinforced concrete slab 12 in. thick. Each tank weighs 12,400 lbs. and was set in place by a Sagsen derrick having a 36-in. boom and a ¾-in. cable. The concrete for the entire vault was poured in 6½ hours, about 60 cu. yds. in all. The Oshkosh saw table was purchased by us last July, and it is no exaggeration to state that it has more than paid for itself. Its portability and general efficiency is such that we could not afford to be without it. For example, last year we took a contract for some remodeling work on a schoolhouse and had permission from the authorities to use all the old lumber in the execution of the new work. The saw table was sent out to the job and it was worked to capacity. When we got through, all you could find was sawdust, literally speaking, for every piece of wood that could be used was disposed of in some manner. Without the saw table we could not have accomplished the results or have done identical work in the same time with inefficient equipment. We do a large volume of business annually because we are equipped to handle most any kind of a job that is likely to be projected in the city of Flint or in our immediate territory."

Two New Concrete Mixers

Two drum concrete mixers which have been accorded a very favorable reception by contractors and builders

Fig. 6—General View of New Mixer Made by Municipal Engineering and Contracting Co.

have been placed on the market by the Municipal Engineering & Contracting Co., 609 Railway Exchange Building, Chicago, Ill. They are known as the No. 0 and No. 1, and have respective capacities of 4½ and 6 cu. ft. of mixed material, the quantities being based according to the wet batch rating of the National Association of Mixer Manufacturers. The construction throughout is steel riveted steel plates and shapes, with the exception of the racks and gears. All operations are controlled from a single position, connections both fixed and operating being of simple and strong construction. The company states that no sacrifice of strength and durability has been made in any part. The charging arrangement consists of a hinged funnel-

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

Modernize

ASK FOR PLAN of an arrangement we have evolved for dormer windows, triple windows and bay windows which has met with wide approval among architects. It effects a considerable saving in construction, cuts down millions to the minimum and in every way has given unqualified satisfaction.

Pullman ^{All} ^{Steel} Unit Sash Balances

used in this connection are fast supplanting cords and weights. They require only a small mortise, and as they have a uniform size face plate the mortise can be cut at the mill when the frames are made. All parts are in the casing—nothing can rub or interfere with the spring action. There is nothing to squeak, rattle, bang or stick. Once installed and it will never require contractors', builders' or architects' attention. There is in every Pullman Sash Balance satisfaction for owner and builder alike. Guaranteed for 10 years. Over five million in use.

Way back in June, 1890, over twenty-five years ago, the General Hospital (Surgical Building), Rochester, N. Y., installed Pullman Unit Sash Balances. They report that these Balances are in fine working order today. Their noiseless operation appealed to them.

In the Wilsonia, a fine modern apartment in Rochester, Pullman Unit Sash Balances are used for all the windows. The windows are large and the service severe. The owner says: "They move as noiselessly and easily as though supported by an air cushion." He also reports a saving of about \$1.00 per window through their use.

Send **TODAY** for our Complete Catalog.

Pullman Mfg. Company, 8 Industrial Street, Rochester, N. Y.

"Keystone Lock Joint Clamp"

Patent applied for

These clamps are made from high grade spring steel, with convex face and acute angled flanges, which engage corresponding grooves formed in backs of the parts to be joined together, as shown in illustration.

When driven in place, the clamps, owing to their compensating spring construction, exert a constant pressure on the edges so joined together, making a joint which remains tight under all changes of climate or temperature.

To secure the best results, specify and insist upon the use of the "Keystone Lock Joint Clamp" on all mitre trim joints.

We use the "Keystone Lock Joint Clamp" on all our erected trim without any additional cost to our Customers, giving them, as always, MAXIMUM VALUE AT MINIMUM COST.

Send the undersigned information regarding your

shaped steel plate hopper which, when lowered, can be filled from the ground level by wheelbarrows. A simple cable hoist elevates the hopper for discharging into the drum. The discharging arrangement is a swinging chute operated by a hand lever. Any part of the batch, or the whole batch, may be discharged at one time by suitable manipulation of the swinging chute, and when mixing, the chute is completely removed from the possibility of catching and discharging portions of the batch. The No. 0 mixer is rated with a daily output of 50 cu. yds. when operated by a 3 hp. hopper-cooled gasoline engine. Specifications for this size call for a steel frame, steel axles and steel wheels. The size of the front wheels is 16 x 2½ in. and the rear wheels have dimensions of 20 x 2½ in. The drum is made of blue annealed steel and the heads are semi-steel. Chilled friction rollers are provided and a friction clutch is between the engine and the mixer. The No. 1 mixer is driven by a 4 hp. hopper-cooled gasoline engine and has a daily output of between 70 and 80 cu. yds. The size of the front wheels is 24 x 5 in. and rear wheels 36 x 5 in. The engine is covered with steel housing and there is a charging elevator and water tank. The elevating and discharge levers are operated from the discharge side of the machine. A view of one of the mixers is shown in Fig. 6. Mixers are also made with capacities of 7½ and 10 cu. ft. A special catalog may be had on application to the company.

Tube for Storing Blue Print and Drawing Paper

A device which will at once appeal to the architect, the draftsman, the builder and the engineer is the "Security" tube for protecting and storing blue print

Tube for Storing Blue Print and Drawing Paper—
Fig. 7—View of the Tube

paper, tracing cloth and drawing paper, which has just been placed on the market by Kolesch & Co., 138 Fulton Street, New York City. The tube, a general view of which is shown in Fig. 1, is made of heavy tin japanned black and is supplied in three lengths—30 in., 36 in. and 42 in. The tube is provided with brackets so that it can be fastened to the drafting table or to the wall according to preference. The paper is easily loaded into the tube simply by pushing back the slide cover and closing it, the paper remaining thoroughly protected without again opening until the entire roll has been

Fig. 8—A Sheet Drawn Out of the Tube Ready to be Cut Off

used. When a sheet of specified length is desired the attached spring measuring-tape is drawn to the required length, the paper or cloth drawn out accordingly and is easily cut by means of a straight cutting edge provided for the purpose. An idea of the operation may be gained from an inspection of Fig. 2. The claim is made that the Security tube affords every convenience to the user

(Continued on page 90)

Dead Weight and Live Weight

"Did ye ever stop to figger out why it is that a 150 pound dead man is twicet as heavy to lift as a 150 pound live man?"

"Or why yer kid weighs twicet as much when he goes asleep in yer arms as he did when he was laffin' and kickin' and huggin' ye round the neck?"

"I'll tell ye the reason—it's because the dead man or the sleepin' kid don't respond to yer lift—they jest sag back; all dead weight.

"It's exactly the same with wheelbarrows. Some are so loose in the joints that they sag back and sway sideways kind-o squeechy-like—resistin' your pull instid of respondin' to it.

"Gosh! but that makes heavy work fer the poor devil between the handles!

"*Sterlings* are different—they respond—come right up smilin'; kind of joshin' you fer not givin' them a real 'man-size' load to carry when they're already carrying, say, 1,000 lbs.

"I'm kinder puzzled to know the why of it and hope some scientific feller will come along some day and explain."

TIM TRUNDLE

When you meet "Tim" tell him the easy lifting of **Wheelbarrows** comes chiefly from two things: one is the correct balance of its load, and the other is that handles, legs and wheel mountings are so joined and braced that they're as staunch as if they were one piece of spring steel full of life and rebound.

Sterling Wheelbarrow Co.

POSSIBLY you have not given the matter of Garage Hardware very much thought. It will be of interest to you to know that

Stanley Garage Hardware

manufactured by the largest and oldest makers of Wrought Steel Hardware in the world is especially designed for modern garages: concrete, stone, brick or wood.

Stanley Garage Door Holder No. 1774

This is strong and simple in construction. It holds the door open, prevents it from banging shut and damaging the car. A pull at the chain and the door is free to swing shut.

Here is a necessity for every garage, and owing to the great number of automobiles being purchased and the large number of garages being built it is particularly worthy of note, *now*.

Write for the Garage Hardware catalog illustrated above. It is really interesting. Stanley Garage Hardware may be had at most hardware dealers.

and positively eliminates all waste, loss of time and the inconvenience of opening and closing a tube every time paper or cloth is required.

New Models of Triple "A" Floor Smoothers

With a view to meeting the increasing requirements of the trade the Triple "A" Machine Company, 4101-4105 Ravenswood Avenue, Chicago, Ill., has just added to its assortment two new models of Triple "A" spring-

New Models of Triple "A" Floor-Smootheser—Fig. 9—View of Model "F"

driven floor smoothers, illustrations of which are presented herewith. Fig. 1 shows a general view of what is known as model "F," which, although somewhat simplified in construction, embodies the essential Triple "A" features that have made the old standard floor smoother so well known to the trade. In Fig. 2 is shown a general view of model "G." The machines are spring-driven and herein, the company points out, lies the secret of the great success of the Triple "A" floor smoother, as its powerful automatic motor spring pulls about two-thirds the load on the cutting stroke, and this aids the operator in a simple and most effective manner. In operating the machine it is only necessary to push it forward. The spring automatically stops the machine and starts it back on the cutting stroke, thus relieving the operator of fully two-thirds of the effort. The claim is made that the machine has the necessary amount of weight to make a scraper of any size cut full depth the entire length of the stroke, thus avoiding the grit and making a smooth cut. Attention is called to the fact that the machine

Fig. 10—General View of Model "G"

has opened a new field of floor scraper, as with the spring-driven floor smoother it is as simple a matter to scrape a varnished floor as any other kind, thus making the machine of special interest to carpenters, painters and others having old or varnished floors to refinish. Floor scraping as a "specialty" has been found by a great many carpenters to be a good paying

(Continued on page 92)

Stanley Tools

Stanley Adjustable Try and Mitre Square No. 21

One of the handiest tools in a Carpenter's Kit. Especially useful for doing short work about windows, doors, etc., or in putting on butts or locks.

The Blade is adjustable, and as it can be reversed, provides any size of try or mitre square within the capacity of the tool. In reversing, it is not necessary to remove the blade from the handle, consequently the tool is always assembled and ready for use.

The locking device is such as to insure the blade being firmly and accurately secured at any point desired. The edges of the Blade are machined, graduated in 8ths, 16ths and 32nds of inches, and the tool is square inside and out.

It is also an excellent depth and marking gauge.

Both Handle and Blade are nickel plated. Made in three sizes.

6 in. Blade, each, 55 cents; 9 in. Blade, each, 65 cents; 12 in. Blade, each, 75 cents.

LEAD PAINT Dovetailed On

PURE white lead is metal lead in another form. Under a blow-pipe flame, it returns to the metallic state. A building painted with strictly pure white lead and pure linseed oil, like

Dutch Boy White Lead

and Dutch Boy linseed oil, is sheathed in a solid coating which, while not lead, is derived from this durable metal and has many of its characteristics.

This lead-like sheet, instead of being nailed on, might be said to be dovetailed fast, for it is held by thousands of tiny tentacles of the coating material itself. It is only as thin as paper but plenty thick to withstand the extreme changes of wet and dry weather and of burning heat and biting cold.

NATIONAL LEAD COMPANY

New York Boston Cleveland Chicago
Cincinnati Buffalo St. Louis San Francisco
(John T. Lewis & Bros. Co., Phila.)
(National Lead & Oil Co., Pitts.)

business. It takes very little effort to find any number of floors which need re-surfacing and most of the owners are willing to pay a fair price for having the work done. The trouble heretofore has been that it was too hard work to scrape a varnished floor by hand, and many were therefore loath to take the job except at what might be regarded as an exorbitant price. With the equipment here described, however, this class of work may be made a most profitable enterprise on the part of the carpenter-contractor. The company has just issued a new catalog describing in detail the new models and we understand a copy will be sent free to any address upon application.

Catalog of Builders' Hardware

Architects, builders, carpenters, contractors and house owners generally are likely to be interested in the very attractive 96-page catalog of builders' hardware which has recently been issued from the press by the National Mfg. Co., Sterling, Ill. The printing is upon a fine quality of surfaced paper and the numerous illustrations are brought out with a clearness which renders the catalog a pleasure to examine. The leading lines of specialties are presented in attractive style and accompanying each is brief descriptive data covering features concerning which the architect and the builder are interested. Attention is called to the fact that instead of the electro-galvanizing process which the company has always used in the past it has now adopted the process of rust-proofing metal called Sherardizing. In this treatment the parts, after being thoroughly cleansed, are put into a large steel drum with zinc dust. The drum is then securely closed, placed in an oven and heated to about 700 deg. By this means the molecules of the steel become active and the zinc dust penetrates into the skin of the steel and forms a zinc-alloy, or in other words becomes part of it. It is said that Sherardizing cannot peel off or crack and will last for years.

New Style of House Construction

The attention of builders is being directed to a new style of house construction which has been invented by E. P. Caldwell, 15024 Marshfield Avenue, Harvey, Ill. Each side wall, ceiling, etc., is formed of a single huge block covered with gypsum stucco. These blocks are joined together, making a house which is practically one solid piece. The walls go down to the bottom of the foundation, and above ground they have a 4-in. dead air space, tending to keep the house cool in summer and warm in winter. Pictures of the building of a house in various stages of construction, together with full description, are contained in a folder which he issues. Mr. Caldwell claims that a house can be put up much quicker and at much less cost than usual. It is said to be fire-proof, cyclone proof, moisture proof, durable and at the same time sanitary and scientific in its construction.

The Concrete Dope Book

We have just received from the Cement Tile Machinery Company, 124 Rath Street, Waterloo, Iowa, a copy of the little work which has been so extensively advertised in various publications during the past few months. The company makes announcement that the book is now ready for the contractors of the land who have so numerously requested that a copy of it be sent them. We understand it is the intention of the company at this time to make it an annual proposition. Deviating from the usual routine of issuing a catalog, the company has taken the problems of the concrete man into consideration and combined a few pages illustrating and describing Winner mixers with a few pages of concise information that will be found of value to the building-contractor in his every-day work. Great pains have been taken in the selection of the tables, figures and data presented in the book although the company does not guarantee that they are absolutely correct in every instance, but they are submitted as a basis for forming and checking builders' own calculation. Among the more interesting tables are those showing the cost of solid concrete foundations, the materials

The Answer to the Outside Painting Problem **ZINOLIN**

NAME the most difficult-to-meet requirements you ever made of any paint before using it or specifying it. Then, from the below list, see if Zinolin, the "Arnold-ized" Zinc, has not only met but exceeded any expectation you ever dared hold concerning a paint.

This Revolutionary Paint—

- 1—Permanently holds its luster.
- 2—Gives a whiter white than ever before known for outside.
- 3—Holds its colors absolutely fast.
- 4—Covers 30% more surface per gallon than white lead.
- 5—Does one coat work which quite often equals two.
- 6—Hides jet black with two coats of pure white.
- 7—Gives a tougher, more durable coat.
- 8—Does not crack, chalk, blister or peel.
- 9—Is easier and quicker to apply.
- 10—Breaks up easier than white lead, saving the painter's time.

required for 100 sq. ft. of concrete floor, also for 100 sq. ft. of concrete sidewalk with figures of actual cost of 100 lineal ft. of sidewalk and of 1000 sq. ft. of sidewalk. There are also given the quantities of materials required for plaster work of various kinds; the materials required for 1 cu. yd. of concrete; the proper thickness of walls and quantities of materials for different heights of basements; the cost of various classes of concrete construction; the thickness of foundation walls for buildings of various heights; cost of concrete blocks of various mixtures; the number of common brick required for different walls; estimate of quantities for plaster and mortar; cost of exterior plastering and material required, together with much other helpful information.

Two Mammoth Concrete Mixers

There has just been completed by the T. L. Smith Company, 3120-F Hadley Street, Milwaukee, Wis., two concrete mixers which are probably the largest ever turned out in this country. Each one of these two Smith tilting mixers has a capacity of 108 cu. ft. of mixed concrete per batch, or between 150 cu. ft. and 160 cu. ft. loose unmixed material. They are in fact two 4-yd. concrete mixers. The circumstances attending their manufacture are in effect as follows: The Hardaway Contracting Company of Washington, D. C., recently secured the contract for an immense concrete dam to be built at Salisbury, N. C., the contract requiring them to pour 60,000 cu. yds. a month until the job is finished,

Fig. 11—One of the Mammoth Concrete Mixers Made by the T. L. Smith Co.

or a total of about 1,000,000 cu. yds. The company found that four 2-yd. mixers would occupy too much lateral space and it therefore became absolutely necessary to use two 4-yd. mixers. The Hardaway Contracting Company had been using a titling type of mixer but not a Smith. They therefore went to the manufacturers of the machines they had been using and showed them the specifications, but that concern was not in a position to build them, so the Hardaway Company called upon the T. L. Smith Company, who made up specifications and stated that it was in a position to erect mixers that could do the job and at the same time would take care of the capacity desired. The result was an order for the two machines. From an inspection of Fig. 11 it will be seen that the machine is mounted on steel skids with an enormous batch hopper supported by a steel frame. The mixer itself is equipped with power tilt and also with Allis-Chalmers clutch pulley. The mixer drum is made of $\frac{3}{8}$ -in. steel and the inside diameter of the drum ring is 9 ft. 5 in. The height of the machine as compared with an ordinary size man may be gathered from an inspection of the picture. The weight of each machine is 46,000 lb.

New "Classik" Ceiling Catalog

Some new effects in stucco and Colonial designs are presented in "Classik" Catalog No. 21 which has just been issued from the press by the Berger Mfg. Co.,

(Continued on page 96)

Two Legs Better than One

That is reasonable whether you are talking about Building Brackets or men. There is just as much difference in the stability of the "Trouble-Saver" Building Bracket with two legs and the ordinary bracket with one leg as there is in the stability of a man with two legs and another man with one. The

"Trouble-Saver"

Building Bracket

is absolutely solid—no wobble at all. The legs brace against each other. Each unit is capable of sustaining one ton.

You can erect as many "Trouble-Saver" Building Brackets in 5 minutes as you can wooden brackets in 5 hours.

Use "Trouble Savers" and save time and material.

Rex Roofing and Shingles

One of the most attractive examples of trade literature which it has been our recent privilege to examine is the 112 page catalog relating to Rex Products which has just been issued from the press by the Flintkote Mfg. Co., 98 Pearl Street, Boston, Mass. Among the early pages are some interesting comments stating the

Rex Roofings and Shingles—Fig. 12—Laying Rex Strip Shingles

best way to purchase Rex Products, also information for use in ordering goods to be shipped direct by the company and a few words which are addressed to those who have not used the goods in question. The illustrations for the most part are halftone engravings, many of which represent buildings in connection with which the company's product has been used. Considerable attention is given to the exposition of the merits of Rex shingles which are described as "a standard roofing material for residences, bungalows, churches, schools and for all sloping roofs where an attractive, durable and fire-resisting roof at a moderate price is wanted." Rex Cut Corner Shingles are made by cutting off two of the corners of Rex shingles, these being offered in two colors—dark red and grayish green. In quality and durability the two are the same and both are guaranteed for ten years without painting or renewal. Rex Strip Shingles are also made in two colors and consist of strips of heavy roofing each 10 in. wide by 32½ in. long, so cut that when laid on the roof each strip looks exactly like four separate shingles. Only five nails are said to be required for each strip of four Rex shingles, thus effecting a great saving both

Fig. 13—Another View of the Laying of Rex Strip Shingles

as to nails and the labor of nailing. Only 111 strips of four shingles each are required to cover a square of surface, the strips being laid 4 in. to the weather. In Figs. 12 and 13 we show the manner of laying Rex Strip Shingles, the statement being made that two men in Milwaukee laid 14 squares of "strips" on a straight roof in 8 hr. These shingles are made of heavy-weight felt thoroughly saturated with high-grade asphalt. An extra heavy asphalt coating is then applied to the upper side of the felt and while this coating is hot there is

LOUDEN

GARAGE DOOR-HANGER

Low enough in cost for the cheapest garage—Classy enough in appearance for the most particular buyer.

Swinging doors for a garage are clumsy and inconvenient. A sliding door track that extends to a post in the yard takes up valuable room and does not present a neat appearance.

The Louden Special Garage Door overcomes these faults, and is far superior to any other type. Being hinged in three parts it follows a very short curve in the track and creates no waste space, either inside or outside the building.

The track is supported every 12½ inches by a strong malleable bracket; cannot sag or get out of shape. The door always hangs true. The swiveled trolleys are roller bearing. They cannot bind or jump the track. One section of the Louden Garage Door swings like an ordinary hinged door.

Prices per set, including all hardware for door, range from \$3.70 to \$4.15. Write for booklet No. 9.

THE LOUDEN MACHINERY CO.
5402 Court Street, Fairfield, Iowa

rolled and compressed into it an even layer of natural chipped red or green slate selected for its rich permanent colors.

Another portion of the catalog under review is devoted to Rex-Tile Shingles, which in their method of laying differs from other shingles. They are nailed at the butt end and no nails are exposed to the weather. The lower end of each Rex-tile shingle is folded back 1½ in. and two nails are driven through this fold and not through the face of the shingle. This folding is done by patented machinery and when sent out the shingles are ready to lay. The value of this simple fold is said to be first in the fact that a Rex-tile roof is absolutely wind-proof, as the shingles can neither blow up nor curl up. Again they can be used on all kinds of covered curved surfaces because they are fastened at the butt and also for this reason they are more satisfactory for siding than would otherwise be the case. These shingles are made in a beautiful soft shade of Indian red which harmonizes with the color scheme of stucco and concrete houses, and bluish black which is said to be suitable for use wherever the color of slate would be in good taste.

Other portions of the catalog are given up to Rex Canvas Roofing, which is especially adapted for covering sleeping-porch floors, verandas, balconies, piazza roofs and decks of all kinds; Rex Flintkote Roofing, which is intended to be used on any roof having a slope of ¼ in. or more per lineal foot; Rex Slate-surfaced Roofing furnished in reels 32 in. wide and 46 in. long; Rex Valley and Ridge Strip; Zarex Roofing; Mikado Roofing; Rex Roof Paints, Waterproof Paper, Adamant Flooring, etc., etc. A number of pages are devoted to an interesting description of roofings of other types, including wood shingles, slate, asbestos shingles, terra cotta tile, tin and corrugated steel, the object being to place trustworthy information before those who have had but little roofing experience, so that they may be able to choose wisely. Directions are given for measuring roofs, also for laying Rex Products, the instructions being illustrated by means of sketches so as to render every point readily understood. A comprehensive index completes the catalog.

Here's a New Vise "YANKEE" No. 1993

With Swivel Base. DETACHABLE

Quickly detached from swivel base by the turn of a set screw; and being accurately machined all over can be used in any position as a jig for special work on drill press, shaper, etc.

Holds work rigid at any angle with use of the special grooved block.

The swivel base is easily and firmly locked and released in any position by a short movement of lever at the side. Jaws 2¾ in. wide, 1⅞ in. deep, opening 3½ in., base 7½ in.

Ask your dealer to show you.

Let us send you the "YANKEE" Book. A postal brings it.

Tells you all about the "Yankee" line

Improved Architects' Wye Level

A level which embodies a number of interesting and valuable features and which is being brought to the attention of architects throughout the country is that illustrated by the engraving Fig. 14. It is a high-

Fig. 14—View of Improved Architects' Wye Level

grade improved wye level and is offered by the New York Blue Print Paper Co., 58-60 Reade Street, New York City. The complete instrument weighs only 5 lb. and the tripod 6 lb. The wyes are provided with a locking arrangement which securely fastens the clips. The level is provided with improved clamp and tangent screws with counter spring. The horizontal circle of 3 in. diameter is graduated to degrees and the vernier reads to five minutes. The 12-in. telescope with which the level is provided is achromatic and has a magnifying power of nineteen diameters. The object glass is 1 3/16 in. in diameter and has rack and pinion focusing with adequate protection to the glass. The 5-in. spirit level is ground to a sensitiveness of sixty seconds and is graduated on glass. The level is ribbed, thus reducing the weight while maintaining its strength.

W. E. Dunn Mfg. Co.

416 24th Street, Holland, Mich.

Pa., calling attention to the three "specials" which were being offered and known respectively as the "Carpenter's Special," "Mechanic's Favorite" and "Expert's Choice." Each represents a special length, is made of crucible steel with a deep tooth and the correct angle that will assure the greatest efficiency. Special notice is directed to the announcement of the manufacturers that a complete sample set will be sent prepaid to any building mechanic on receipt of a special price if not sold in his own town.

Frank H. Moss Makes New Business Connections

Announcement is made of the fact that Frank H. Moss, after seven years' service, has severed his connection with the Mahin Advertising Company, and has joined the forces of the Macavoy Advertising Company, Chicago, Ill., assuming the office of vice-president. He

is well known in the business world for his merchandising work and sales plans, and in his new connection will have direct charge of merchandising investigations and sales campaign development. Many building-contractors and plumbers throughout the country are acquainted with Mr. Moss, as it has been his practice to consult with them for the purpose of obtaining their viewpoint before undertaking an advertising campaign. Mr. Moss is the author of a brochure

entitled "Putting it Thru—Not Over," which has attracted a great deal of attention for its presentation of the ethics of modern business.

Berry Rockwell, formerly associated with Mr. Moss while connected with the Mahin Advertising Company and prior to that merchandising expert for the Curtis Publishing Company, has also joined the Macavoy Advertising Company. Another addition is Gridley Adams, who for the past three years has been advertising manager for the Stewart-Warner Corporation. The addition of these three men to the staff of the Macavoy Advertising Company is a part of the plan for a new type of advertising service which combines with the usual principles of service real merchandising work that has proven a great benefit to all using it.

New Location for Triple "A" Machine Company

During the past year or two the demand for Triple "A" floor smoothers has been such as to interfere many times with prompt shipment, and with a view to providing increased facilities, the Triple "A" Machine Company has moved into its new factory and offices at 4101 and 4105 Ravenswood Avenue, Chicago, Ill. It has discontinued its factories at Manistee, Mich., and Harvey, Ill., and will combine its entire output at the new Chicago plant.

Natural Wood Finishing

The proper finishing of exterior and interior wood-work is a question frequently confronting the practical carpenter, builder, painter and finisher, especially in the case of the popular hardwood finish. The materials which must be used in order to secure a uniform finish under all circumstances and which brings out the beauty and natural characteristics of the wood becomes of paramount importance. Interesting information on the proper materials to use is contained in a booklet bearing the title "Natural Wood Finishing," which has been issued by the Eugene E. Nice Co., 201 Spruce Street, Philadelphia, Pa.

Slate and Slate Products

A Digest of Slate and Slateroofers' Supplies has been compiled for the slate trade by J. Bray & Co., East Bangor, Pa., and within the covers of the little work is described the best method of putting on slate. It states that slate should never be laid flat in piles, but always on edge, as near perpendicular as possible, never putting more than three piles on top of each other with lath or board between them. Interesting information

is also given on estimating the amount of slate required for a roof. The company is prepared to furnish on quick demand all slate products and to give a certificate with its roofing slates which states that the material contained therein is "genuine Bangor slate."

Summer School of Manual Training

The courses in manual training pursued at the summer school of the Bradley Polytechnic Institute, Peoria, Ill., are set forth in a pamphlet which is being sent out by the management. The courses are planned with special reference to the needs of teachers, and specialization in the fundamental processes of a variety of handicrafts suitable for schools. The courses include the use of wood working machinery, furniture making, wood finishing, pattern making, etc.; architectural, mechanical machine and freehand drawing; the study of interiors; cement construction, the laying of floors and sidewalks, making of molds, properties and methods of use, etc. The course is from June 19 to July 21.

TRADE NOTES

W. E. Dunn Mfg. Compny, 416 Twenty-fourth Street, Holland, Mich., is offering to send to builders a copy of its free book on concrete machinery. It is not exactly a catalog because it gives the cost of making a number of concrete products, such as porches, chimneys, fence posts, building blocks, etc., and also tells about the profits in drain tile making for farmers. A copy of the book will be sent free to anyone sufficiently interested to apply to the company.

Amalgamated Roofing Company, 431 South Dearborn Street, Chicago, Ill., calls attention to the fact that its Nu-Tile Asphalt Shingles are fire-resisting and that this fact has given architects and contractors specifying and using them a reputation which has resulted in many houses being protected by this form of roof covering. The shingles are made in red, moss green and white colors, are waterproof, fire-resisting and durable.

The Loudon Machinery Co., 5402 Court Street, Fairfield, Iowa, points out that its special garage door overcomes many of the objections which are often urged against sliding and swinging doors, and which is sufficiently low in cost to command instant attention. The Loudon door is hinged in three parts and follows a very short curve in the track so that no waste space is created either inside or outside the building.

One of the latest candidates for popular favor in the way of a wallboard is what is known as the "Black Rock," a stiff four-ply board having what is described by the company as a "moisture-repellant black center." It is made by the Black Rock Wallboard Company, 1525 Ontario Place, Black Rock, N. Y., and the claim is put forth that the well sized, smooth "sanded-like" surface of Black Rock needs less paint—no priming coat being necessary—and retains that "fresh-painted" look which is so satisfactory to the house owner. The company has issued a booklet relating to this wallboard which it will send free with sample of the material to any architect or builder who may make application for it.

U. S. Mineral Wool Company has removed its New York City office to 280 Madison Avenue.

Clinton Wire Cloth Company, 51 Parker Street, Clinton, Mass., has issued an interesting book entitled "Successful Stucco Houses," a copy of which any reader of THE BUILDING AGE may obtain free. Another booklet which cannot fail to interest is entitled "Clinton Hand Book on Lath and Plaster."

The April issue of the house organ of the North Western Expanded Metal Co., 904 Colony Building, Chicago, Ill., contains some interesting information regarding building trade conditions in various cities of the country. The Bulletin is illustrated by halftones of various prominent buildings in which metal lath has been used for exterior or interior plastering and these are accompanied by a few lines of description pointing out important architectural features. Expanded Metal

Build With Stucco But Give a Backbone of **SYKES** Expanded Cup Metal Lath

No Furring Strips Required

Stucco Buildings are becoming more and more popular because of their economy and durability. Many builders are converting frame houses into handsome stucco houses by overcoating.

Sykes Metal Lath is the logical material to use with stucco—either building or overcoating work—because

It Gives More Weight for same gauge than other metal laths—therefore more strength and durability.

It requires less mortar.

It keys perfectly.

Sykes Expanded Cup Lath requires no furring strips and so saves 5 to 10 cts. a sq. yd. in building costs.

The builder experienced in metal lath work will be careful to judge a metal lath not by gauge alone but by gauge and weight. Sykes Expanded Cup Metal Lath being cut from wider strands than others has more weight. This is a very important advantage.

Best for interior as well as for exterior work—Sykes

Approved by U. S. Government for Post Office Work

The Sykes Booklet—Complete Specifications for Stucco on Metal Lath—is sent free on request. Will show you how to build better and save. Free sample of Sykes Expanded Cup Metal Lath. Write us today.

Sykes Metal Lath and Roofing Co.
494 River Road, Warren, Ohio

Lath, as is well known, is so constructed as to conform to the strictest fire resisting requirements and can be shaped to follow the distinctive designs of an architect without trouble or excessive expense in labor.

The Standard Scale and Supply Co., has removed from its old location in Water Street to 1631 Liberty Avenue, Pittsburgh, Pa., where it will enjoy commodious quarters more in keeping with the requirements of its growing business. It has also moved its New York City office to 145 Chambers Street.

Announcement is made that the Berlin Machine Works, Beloit, Wis., has changed its name to P. B. Yates Machine Company. The statement is made that ever since the business was founded forty years ago in the little Wisconsin town of Berlin, from which it took its name, considerable annoyance has been experienced through the adoption of this name by many other small concerns established in cities of the same name in various states. In the interest of its patrons and the good will and prestige enjoyed, the company has concluded to change its name as above, this change being confined to name only, as officers, capital and policy will remain as heretofore.

King Elevator Company, Inc., 397 Bedford Avenue, Brooklyn, N. Y., and Bridgeport, Conn., has recently issued from the press an illustrated catalog relating to the various lines of dumbwaiters, ash hoists, sidewalk and freight elevators which it manufactures. Special reference is made to the Simplex dumbwaiter which is said to be suitable for all classes of buildings and particularly so where a dumbwaiter of moderate cost is required. The company makes a specialty of high grade private house and investment work and all machines are built to order to fit each individual hatch and meet the requirements they are called on to perform.

The Automatic Sash Holder Mfg. Co., 46 Church Street, New York City, calls attention to the fact that its automatic sash holders being cheaper than sash weights, cord and pulleys, are calculated, in view of the tremendous rise in the price of iron, lead, zinc and other metals, to receive more than ordinary consideration on the part of architects and builders. The sash holders are referred to as being simple of construction and that it is only necessary to put a mortise in either the sash or the frame, insert the holders and the window can be raised and lowered at will. The devices can be installed wherever there are any pocket frames and are suited for economical window construction.

Two booklets upon doors which are being widely distributed by the Hyde-Murphy Co., Ridgway, Pa., are of special interest to the architect and builder. One describes the "no-warp" construction of doors made by it. The device used in keeping the joints together consists of a clamp made of spring steel with slightly convex faces and acute angle flanges, which engage corresponding grooves formed in back of parts to be joined together. When driven in place these clamps are invisible and exert a constant pressure on the edges so joined together, making a joint which remains tight under all changes of temperature or climate. The other booklet contains illustrations in color and prices of the various veneered doors which it manufactures.

"Ideal Ideas" is the title of a booklet which has been published for the purpose of showing the uses of Ideal concrete block construction. Reference is made to the advantages of concrete blocks and a brilliant array is presented of halftone engravings covering buildings of all kinds which have been erected by the use of Ideal blocks. Among the later pages of the booklet are shown some of the many forms of blocks which may be produced on Ideal block machines. The booklet is sent out by the Ideal Concrete Machinery Company, 1310 Monmouth Avenue, Cincinnati, Ohio, and although its name does not appear in connection with it, a panel at the bottom of the first page is left blank for the name and address of the customer to whom the company supplies the pamphlet in 500 or 1000 lots, thus giving the customer a better catalog at a lower price than he could

**The Stiff
4-Ply
Wallboard—
Black Rock**

**Build Your
Reputation
on
Black Rock**

BLACK CENTRE

REGISTERED TRADE MARK

The last word in wallboard

AT LAST—HERE IS A WALLBOARD that will win the enthusiasm of every conscientious contractor. For Black Rock (in addition to being as-stiff-as-lumber) is the only wallboard with a *moisture-repellant black centre*.

As a man who knows lumber, you will recognize that the *veneer* process of combining the four plies, makes Black Rock the *stiffest* and *strongest* wallboard. That's why it looks, works and lasts like high-grade, kiln-dried finishing lumber.

And here's good news for the progressive contractor who has his future reputation at heart. Black Rock will not warp, buckle, bulge, or pull away from the nails. For, in addition to the moisture-repellant black centre, the new scientific process of *moisture-proofing* the front and back surfaces of Black Rock removes the principal causes of contraction and expansion.

These are a few of the reasons why Black Rock pleases permanently. Moreover—the well sized, smooth, “sanded-like” surface of Black Rock needs less paint (no priming coat necessary) and *keeps* that fresh-painted look. The price of Black Rock will interest you.

BLACK ROCK WALLBOARD CO.

Trench or Mud Pumps

Small Hoist

Reversing Type Hoist

probably put out himself, not having the materials at hand to make up a booklet of this nature.

A booklet which contains just the kind of information desired by the carpenter and builder has been sent out by the Maple Flooring Manufacturers' Association, 801 Stock Exchange Building, Chicago, Ill. It is entitled "How to Lay and Finish Maple Floors," and describes the making of a good job from the delivery of the wood to the final touches given by the skilled workman in finishing a floor. The advantages of maple flooring are set forth in other booklets issued by the company and entitled "School-room Floors," "Ten Reasons Why" and "Individuality in the Home," the latter containing arguments likely to appeal to the owner or housewife. The booklets also touch on beech and birch flooring when that kind of a finish is desired.

The Walter Concretile Mfg. Company plans to establish a plant in Fremont, Ohio, for the manufacture of roofing materials. It is stated that the company will occupy quarters in the present plant of the Fremont Waterproofing Company.

The fence question is often a perplexing one, and in order to aid in its solution a booklet containing illustrations and prices of some of the many fences which it manufactures has been issued as a guide by the Wright Wire Company, Worcester, Mass. The company states that "Excelsior Rust-Proof Fences" are made entirely of large wires unweakened by binds, wraps or twists. Each joint has a patent steel clamp holding the wires in a vise-like grip. It is stated that the fence is galvanized after making, by dipping the entire fabric in pure molten zinc, thus rendering it rust-proof.

"Garage Doors" is the principal subject treated in the April number of *Doorways*, the house organ of the Richards-Wilcox Mfg. Co., Aurora, Ill. The article discusses various types of hangers made by the company and there is also a clever joke column to amuse the casual reader.

B. H. Fontaine has recently opened an office for the practice of architecture at 313 Louisville Trust Building, Louisville, Ky., and is desirous of obtaining catalogs and samples from manufacturers of building materials.

Edwin B. Bennett, for over twenty years Western manager of the Eagle White Lead Co., Cincinnati, Ohio, died on Thursday, March 30, at his residence, 1724 Park Avenue, Chicago, at the age of 71. He has resided in Chicago for fifty-nine years. He is survived by a widow and four sons.

Lewis Brothers, Lima, Ohio, have completed plans for a one-story factory building 110 x 150 ft., the erection of which will be started at once. The plant will make veneer doors and other interior finish.

The increased cost of materials and labor in house painting makes it necessary for the painter to raise his prices if he expects to show a profit at the end of the year is the intimation contained in a recent issue of the *Carter Times*, the house organ of the Carter White Lead Co., West Pullman Station, Chicago, Ill. A sample paint and labor estimate is given and there is also a table showing how to figure overhead charges and their constituent parts. The company realizing the importance of proper publicity is offering slides for use in motion picture houses, mailing cards and letters for use in "Clean-up and Paint-up" campaigns, etc., free to painters using Carter paints.

Decorative Concrete

Our processes for the exact and permanent reproduction in concrete, of marble, granite and onyx effects in all colors, are what we have to sell.

Write us for particulars and prices.

ART STONE CO., Box 500, Waynesboro, Pa.

The Austin Drum Mixer

Turns out a well mixed batch at the rate of 60 to 80 cubic yards a day. The Power is furnished by a 4 Horse Gasoline Engine. All operations are controlled from a single position. The drum is operated with a combined endwise and circumferential plowing and pouring movement—the most efficient of all drum mixing movements.

Made by the Manufacturers of the AUSTIN CUBE MIXERS

Every contractor knows the justly famous Austin Cube Mixer, and hopes some day to own one, but now a sturdy mixer of a cheaper price will serve his purpose. It is for such men that we have built the AUSTIN DRUM MIXER.

Use the coupon printed above for your convenience, and learn more about this dependable mixer.

Blystone Batch Mixer

For Plaster-Concrete-Mortar

A saving of \$25.00 per day was made in mixing hardwall plaster for the big Machinery Palace for the Panama Pacific Exposition.

The Cement Tile & Block Mfg. Co., of Osgood, Ohio, paid for their Blystone in three months work in their block plant.

One man slaked lime and made mortar for ten masons and had time to spare for other work on a job recently done by G. Ed Berry, of Harrisburg, Ill. Mr. Berry also says he got 10% more mortar per barrel of lime.

H. A. Farmer, St. Petersburg, Fla., recently wrote us as follows: "I am so well pleased with mixer, I want another just like it. Ship me another one as soon as possible."

Compo-Board

Trade Mark Reg. No. 94745

—you'll never find another building material or wall lining like this—none so flat and strong, with so slight a tendency to warp or shrink, none so easily handled, sawing so clean and smooth; none so durable; none with such a stubborn resistance to air, cold, heat, moisture and fire. None so adaptable to so wide a range of uses.

Compo-Board has all of these features as a result of its patented wood core construction.

How important it is then that you *get Compo-Board* when you ask for it. You can't be fooled if you look for the wood core, for it is easily and quickly identified.

You can get just the amount you need for any job in strips four feet wide and in even lengths up to 18 feet long.

Sold by dealers everywhere. Write for interesting book and free sample piece.

The Compo-Board Company
5778 Lyndale Avenue No.,

SENT FREE!

Don't take our word for it that these books will enormously increase your earning capacity. Get them into your home or shop—**free**—and determine their value for yourself. The books themselves, not what we say for them, must convince you that you need them, so send the coupon to-day—**now**—and the entire eleven volumes will come to you at once, express prepaid. If, after a full week's trial, you decide to keep them, you can buy them at half the regular price and on the easiest of easy payment plans.

Newly Revised Cyclopedia of Architecture, Carpentry and Building

consists of ten large volumes, handsomely bound in half red morocco, gold stamped, containing 4,760 7 x 10-inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross indexed for quick, easy reference.

PARTIAL TABLE OF CONTENTS

Mechanical, Freehand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

Plan Book and Consulting Service FREE

We give free to every purchaser of our Cyclopedia of Architecture, Carpentry and Building, a copy of "Modern American Homes," a complete and up-to-date plan book. Contains plans and specifications for 168 structures, including excellent exterior and interior views, detailed estimates, etc. Designed by leading architects, it covers city, suburban, and country homes; bungalows; summer cottages; tent houses and camps; apartment houses; garages, and public buildings. 224 pages, 9 1/4 x 12 1/4 inches, and 426 illustrations. Printed on enameled paper and substantially bound. With this plan book in your shop you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect—you can offer him his choice of practically every type of home. This saving of the usual architect's fee should get you the business.

In addition we give free with each set a year's consulting membership in the American Technical Society. Through this service you have the assistance of a staff of architectural and building experts. These men are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

Send for this great combination today

We will send the complete eleven volumes to your home for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet your expectations they may be returned at our expense. If you keep them send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80—**regular price \$50.00**—has been paid. Remember—the consulting membership and plan book are included absolutely free.

Can you afford to let \$2.00 a month—50c a week—stand between you and success? The consulting membership alone is worth many times the first cost of the books. Fill in and mail the coupon—**NOW!**

BAYONNE

FORESTALLS COMPLAINTS

When the ordinary roof-covering begins to warp and buckle, expand and contract with heat and cold; when metals rust and bulge, tars blister and crumble—then the owner will ask some pertinent questions of Architect and Builder. And consequent repairs will only make matters worse.

BAYONNE

forestalls all complaints as well as repairs. It is practically indestructible. Laying is cheap and simple—after that it stays flat. Never corrodes. Never leaks.

BAYONNE gives a well-finished, neat and attractive appearance to the roofs of verandas, porches, decks, etc. And it is the easiest roofing to keep clean and neat because it can be sluiced with water.

LOOK! YOU DON'T FIND OTHER WALL BOARDS LIKE THIS

A Panel of waterproof Plastergon 48x120 stands straight without bending

That's due to the chemical treatment of the wood fibre by which it is actually converted into lumber. With this unusual stiffness, great strength and hardness is gotten so that WATERPROOF Plastergon may be handled and worked like lumber.

Waterproof Plastergon Wall Board

"The chemically treated board that does not shrink"

Freedom from shrinkage is gotten by surrounding each individual fibre with waterproofing gums and oils to protect it from the constantly changing atmospheric conditions.

Hard, Stiff, Waterproof, and Sized

This treatment of the fibre also perfectly prepares the surface of the panels for decorating. It stops the "suction" and eliminates further sizing, saving the user from \$4.00 to \$6.00 per M sq. ft.

BEAVER BOARD

**THE BOARD THAT
MAKES—NOT BREAKS—
A CARPENTER'S
REPUTATION**

MAYBE you've a "grouch" against some wall boards you have used. They probably were so soft and punky that you couldn't handle them. Gunned your saw or crumbled under it; or cut with a ragged edge. Were almost impossible to fit and apply; and then most likely your customers complained about them. But do you know that there are as many "grades" of wall board as there are of lumber? You wouldn't judge all lumber by hemlock. Nor is it fair to judge all wall boards by some that have fallen down on the "job."

UPSON-BOARD

The most dependable Board made in America.

—the highest-grade wall board made—is as different from the "next best" grade as oak is from hemlock. It is a **DEPENDABLE**, satisfactory wall board—in every way. Only long, wily, pure wood fibers are selected. These are combined and compressed, under the Upson formula, into hard, stiff, wood-like panels—made in five thicknesses, ten lengths and three widths, including the great new 64-inch Upson panel which minimizes paneling to the utmost. A board for every purpose. Then, Upson Board is the only

wall board that is **SCIENTIFICALLY PROCESSED**: K₁in-cured, like interior trim; thoroughly water-proofed; surface-filled. Only one or two coats of paint are necessary to finish it perfectly—at a saving of \$5 to \$15 for the ordinary room, over other wall boards. No oil or paraffine in it to cause paint to peel, blister or spot. Write us to-day and we will give you a line on the big money-making possibilities in **DEPENDABLE** Wall Board trade that will surprise you. We shall also send Upson Board samples and give you all particulars.

Marion, Ind.

THERE'S no question at all about the *amount* of business you can get during May if you want to *go after* it. But why not make up your mind to get the *greatest profit* out of the business you do get? Every installation of

UTILITY BOARD

that you make means a nice clean, clear, long, liberal profit for you. No worry about deliveries, no trouble to handle, no "grief" of any kind. And the way you can use **UTILITY BOARD** in cases where you used to depend on other materials is surprising.

The Only Asphalt Pasted All Wood Stock Board

UTILITY BOARD laughs at temperature changes. It resists moisture and wet. Cuts readily to any required size and once properly laid is on to stay.

UTILITY BOARD is honestly made of the best materials obtainable. The fact that it is the only all wood stock board on the market in which the layers are pasted together with water-proof asphalt makes it particularly desirable for contractors and dealers who know good building materials and insist on getting them.

Time Nor Weather Cannot Break the Bond

BEFORE the advent of Kellastone there was no other exterior coating, cement, lime or other stucco that would not come loose from its base, and fall off on account of expansion and contraction due to changes in temperature and by the disintegration due to ingress of moisture.

There is one, and only one, stucco that can be depended upon to overcome these results and that is

KELLASTONE

IMPERISHABLE STUCCO

It bonds with extraordinary tenacity to stone, wood, tile or brick. It hardens like stone, yet has an elasticity which permits it to "give" with the settling of walls to an extent which would ruin other stuccos. You find no separation of the stucco from window and door casings when you use Kellastone. It is practically water-proof, rain-proof, fire-proof—the only stucco that resists the attacks of time, temperature, stress and weather.

Kellastone is your positive dependence. It is being used by the U. S. Gov't, by factories, hospitals, and finest homes everywhere. For beautifying and renovating old houses it is the one perfect material.

Kellastone Composition Flooring is superior to concrete, tile, wood, rubber-tile or other flooring. Has no seams or cracks; deadens sound. Used in schools, factories, hospitals, homes.

Let us give you all the facts about this wonderful material. Write today.

Save 30%
in labor and material costs by
using Keezon Cellular Lath

To firmly fasten a four foot length of Keezon requires but eight strokes of the hammer. Studding can be placed 16" apart instead of 12". Plaster can be more easily applied and less of it used. In every way Keezon has proved itself the best lath for all building purposes.
Keezon is manufactured in standard units and consists of a cellular structure, formed of fibre board and wood heavily coated with a creosote preparation. It is fire-resisting and may be specified in slow-burning construction.
Keezon is rust-proof and moisture-proof; can't warp, buckle, expand or contract. These qualities make Keezon particularly desirable for outside stucco work. It has all the good points of both wood and metal lath, and none of the bad ones.
The largest and best known builders and plasterers in St. Louis use and recommend Keezon. And, for a limited time, to promote the sale of Keezon out-of-town we make a

Special Offer to Architects,
Contractors and Builders

Write for full particulars regarding this offer and booklet thoroughly setting forth the many Keezon advantages. This proposition will interest you exceedingly. Don't fail to use the coupon.

Wright Wire Lathing

Why not reduce the possibility of fire to a minimum in those houses you build by using Wright Wire Lathing?

**Fire-proof
Rust-proof
Sag-proof**

You will find it profitable to use it in walls, ceilings, and for reinforcing concrete floors.

For outside walls and stucco work it combines the advantages of durability and permanence with speedy erection and low initial cost. It is extensively used in houses all over the country, as well as in the largest buildings.

Send for our catalog X describing the use of Wright Wire Lath and Reinforcing.

Wright Wire Co.
Worcester
Mass.

Berger's Economical Building Products

Berger's Expanded Metal Lath For STUCCO Work

A WELL designed and properly constructed stucco home has an unusually substantial and pleasing appearance, and this style of construction is in much demand by discriminating home builders everywhere.

Stucco admits of a great variety of designs, and when applied over Berger's Expanded Metal Lath is economical and durable—incurring no depreciation or upkeep costs.

This combination makes not only a strong construction, but a fire-retardant one as well.

Berger's Expanded Metal Lath is extensively and effectively used for both outside and inside walls. It provides a secure foundation to receive the stucco or plaster and hold it in place. The small meshes allow a perfect "key" or "clinch" with the minimum amount of stucco or plaster.

It prevents cracking or falling off of plaster; does not swell, warp or strain the plaster; does not absorb moisture; prevents rats and mice from making holes through walls; and is quickly and easily applied.

Manufactured in sheets 8 feet long and the width varies from 15 inches to 24 inches—the most popular width being 18 inches. Gauges from 22 to 27, the higher the gauge number the lighter the material.

An interesting booklet on Expanded Metal Lath has just come from the press. Want a free copy? Ask for Booklet F. B.

Ferro-Lithic Reinforcing Plates, used extensively for reinforcing concrete slabs for flat or arched roofs and floors, sidings of buildings, sidewalks, etc.; *Multiplex Reinforcing Plates*, for heavy service floor, roof, bridge and sidewalk construction; *Rib-Truss Reinforcing and Furring Plates*, especially adapted for reinforcing thin concrete slabs for roofs, sidewalls, partitions, and floors; *Corner Beads*, for protecting exposed corners of plastered walls; *Pressed Steel Cores*, for displacing concrete and forming concrete joists in light or heavy construction for long spans. Write for data.

OWNERS want it and like it, because it is a scientifically treated canvas roofing material made so well that it outwears the porch and roof, costs so little that it is by far the most economical to buy.

It deadens the noise of the rain—the rattle of the wind—and will not mildew.

It's easy to lay—hugs the porch tight, and is neat and artistic in appearance.

Write for sample and see how it looks. Try it and see how it wears. Satisfaction guaranteed.

Our new Illustrated Booklet, "ROOFING FACTS AND FIGURES," will convince you and will convince the owner. Send for a copy.

MONTROSS METAL SHINGLES

"I am more pleased with Montross Shingles every day. Everyone who has seen them likes them, and I never fail to speak a good word for them. My roof was struck by lightning last Fall, but the metal scattered the charge, and it did no harm. I expect to build a barn in the future, and shall certainly use Montross Metal Shingles. Many thanks for your more than fair treatment."

U. S. MOORE, Lomax, Ill.

Montross Metal Shingles

Make

"THE BEST ROOF UNDER THE SUN"

Especially adapted for house or barn, or any building that requires a tight, durable, economical roof. Easily applied by carpenters. Nine different sizes and designs to select from. Write for illustrated catalog and testimonials from satisfied customers who have used Montross Metal Shingles for over a "quarter century." Liberal commission to good, live agents.

Montross Metal Roofing Co.
108 Erie Street, Camden, N. J.

The Builder OK's These Shingles

Come Bundled Ready-to-lay

because he is *absolutely* sure of pleasing both owner and architect.

The soft-toned colors are most artistic; they do not fade or wash out in streaks; the quality is "even better than the best" the open market affords.

"CREO DIPT" STAINED SHINGLES

17 GRADES

16, 18, 24-INCH

30 COLORS

—easiest to lay

every shingle sawed from selected live cedar timber, not stumpage; no wedge shapes—all parallel widths. Fit like matched boards.

—bundled, ready-to-lay

stained, dried, inspected and bundled at the factory. Save all the muss and odor. Carpenters like to work with them.

—profitable

Cover more surface, lay faster and without waste—cost even less than staining on the job. Make fine-looking, tight and lasting roof or side walls.

Get your Lumber Dealer to stock three or four standard colors. On reshingling and remodeling jobs, you can make good money and give best satisfaction by using "CREO-DIPT" Stained Shingles.

STANDARD STAINED SHINGLE CO.

Don't Lay
Another
Roof
Until We
Send You a

Winthrop Tapered Asphalt Shingle

Just ask for a sample shingle. See how tough, how pliable and how durable it is. See how it is made like a wooden shingle—thick at the butt and thin at the top. See how easy to lay it is. See what a beautiful roof it will make—red, green or slate-black. Then you will understand why owners want the Winthrop when they know about it.

Winthrop Tapered Asphalt Shingles will enable you to get most of the roofs in your town. They win out with less argument than anything you ever tried to sell, for they look better than wood shingles and they have all the protection of asphalt.

The Beckman-Dawson Company
Asphalt Shingles

Factory: Argo, Ill. 1400 Association Bldg., Chicago, Ill.

The Only Tapered Asphalt Shingle

This roofing is put up in rolls, 32 inches wide; 108 squarefeet in each roll. Packed with nails and cement and requires no more labor than roll roofing.

FLEX-A-TILE ROLL SHINGLE (PATENTED)

ALL the ornamental effect of a slate or shingle covered roof—durable, easy to handle and easy to lay, decidedly economical—these are exclusive advantages that the new Flex-A-Tile Roll Shingle offers you.

IT'S just the same as having a Flex-A-Tile Asphalt Shingle roof when you use the Flex-A-Tile Roll Shingle—in fact it is a Flex-A-Tile Asphalt Shingle Roof except that the shingles are laid in long, 32-inch wide strips or rolls instead of individually. Each shingle is a separate unit, regular, full size with 5 x 10-inch butts—each one stands out by itself, yet they are all in one piece.

FLEX-A-TILE Roll Shingles come in two colors, red and green—the permanent natural colors of their slate surfacing. Neither the pattern nor the color can wear off—they're on to stay; neither paint nor any other imitation process is used in producing this roll. You have to see it to appreciate it.

Liberal Sample Sent FREE

Kno-Burn
EXPANDED
Metal Lath

For Fire Resisting Stair Soffits and Walls in Factories, Buildings Stores, Etc.

The building laws of many states recognize plaster over metal lath as suitable construction for this type of work. It is the cheapest and most practical method and, if metal lath is used, the ideal brand is

Kno-Burn
Expanded Metal Lath

The fine mesh of "Kno-Burn" cuts down the amount of plaster. The smooth surface of "Kno-Burn" is easy and quick to plaster over. You can be sure that the plaster will stay "put" because the mesh of "Kno-Burn" keys the plaster firmly and permanently to it.

There are many other uses for "Kno-Burn" Expanded Metal Lath in special ways that save you money on work. Let us send you "Kno-Burn Expanded Metal Lath," a complete book on our full line, ask for booklet 43.

Gentlemen:-

We have used your "BOSTWICK TRUSS-LOOP METAL LATH" on several of our jobs, and wish to state both from an economic and practical stand-point there is nothing we have ever handled to equal same.

Your metal lath costs a little more per sq. yd. than some of the other cheaper metals, but we find this is more than made up in the saving of mortar and labor.

Yours respectfully,

George Pratt & Sons

Distinctive Interiors

The illustration conveys an excellent conception of the attractiveness and neatness given to the interior of a store by the use of

These ceilings combine the strength of steel with the beauty of moulded plaster—giving at a reasonable cost, an interior of character and distinction.

These ceilings are light in weight, are fire retardant and cannot crack or fall down—eliminating entirely the danger, annoyance and repair expense caused by falling plaster.

Hundreds of beautiful designs, stamped from clay moulded originals, harmonize with any type of architecture and offer wonderful possibilities for decoration.

Berger's "Classik" Steel Ceilings are adapted to any interior—store, home, church,

theatre, garage, office, public building, etc.

Right in your locality there are buildings being erected or repaired in which these ceilings can be installed to the mutual advantage of both yourself and the building owner.

**You Save 25% to 40%
On Every Job**

The improved bead and button construction makes a perfectly tight joint without tamping and calking—a feature that makes erection easy and speedy for you, materially cutting down your installation costs and adding to your profits.

Show our "Classik" Book D. B. to the owner whose contract you're after. Its many designs and typical installations will help you get it. Send for a copy now.

House & Garden represents to the lover of a real American Home that which is newest and most modern in decoration, gardening, town and country life. The May number, now on the newsstands, covers more topics than ever before, and its contents are of a greater variety.

FURNITURE AND HANGINGS

HAVE JUST AS MUCH SOUL AND PERSONALITY AS PEOPLE

HAVE you some friends that do not get along well together? Probably you have studied to bring together these conflicting personalities at dinner, in perfect harmony?

Apply the same study to your furnishings. Why doesn't the Chippendale desk look right, beside the willow settee? Do the chintz hangings really belong in the living room window? Why does that picture in the alcove look out of place? The May House & Garden smooths out these ruffled

dispositions; it tells you how to bring Summer into the house. It features—just at the right time—the furnishing and decorating of the summer home, particularly that out-door living room, the porch. And the garden with its necessary furnishings is delightfully treated.

House & Garden

With which is incorporated AMERICAN HOMES & GARDENS

This handsome magazine of large-page size, has an average of 80 pages of text and pictures per issue. The subscription price is \$3 a year; single copies are 25 cents. But why not try House & Garden for six months at the special \$1 rate?

An investment of \$1 may show you how to save \$100 or even \$1000 or over.

You might easily waste that much on furnishings that do not harmonize, or gardening that does not please, or in building that is not practical. House & Garden removes the probability of error in this regard.

A SPECIAL OFFER

If you will detach and mail the coupon in the lower left-hand corner, you may have the next six issues of House & Garden, with its wealth of beautiful pictures and valuable information, for only \$1.

Detach and mail the order coupon now, before you forget or mislay this advertisement.

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

National Sheet Metal Roofing Co., 339-345 Grand Street, JERSEY CITY, N. J.

Here's the Big, Quick Profit Chance You've Waited For!

OPPORTUNITY is pounding on your door with sledge-hammer blows through this advertisement. In response to our strong advertising in the leading magazines, thousands of people everywhere are demanding Edwards' Metal Ceilings, Tiles and Walls. Our business is growing so rapidly that we must have a good,

live agent in every community. *One representative* is wanted for each territory to demonstrate, take orders and apply Edwards' Metal Ceilings and Walls. Will *you* be the *one* man to reap the harvest of quick, easy profits? It's squarely up to you. But you must hurry. This opportunity won't linger.

Edwards' Metal Ceilings and Walls

Here is a chance to build up an independent, profitable business for yourself right at home. Many are now devoting their entire time to selling our metal ceilings and walls. Others have made big profits simply devoting part of their time to selling and applying our Metal Ceilings and Walls. No matter how you handle the proposition, the profit is in it, because the demand has already been created.

You Must Act Quick

Write us about your territory at once. This doesn't mean next month, or next week, or even tomorrow, but right now! One hour's delay may mean that someone else may be given your territory. Send the coupon. It brings our special agent's proposition and large illustrated Ceiling catalogue of attractive salesmaking designs.

ROOFED WITH ASBESTOS "CENTURY" SHINGLES

Sold or Rented Before the Builder Could Complete Them

Six of these houses on the left side of the street were first erected. All were sold or rented before they were finished. Then the builder erected six on the opposite side. This is the way houses covered with Ambler Asbestos "Century" Shingles and Asbestos Building Lumber go. And that is the way you or any other builder or architect like to see them go.

Property owners are no longer satisfied with mere roofing, they want the kind that is dependable, permanent and costs little or nothing for upkeep. An Ambler Asbestos Shingle Roof is the kind they want, because it is first of all—FIREPROOF. It is water, weather and wearproof. And they are expense proof, too, for Ambler Shingles never require painting, patching or repairing. Once they go on the roof—the expense ends—and the roof looks good—forever. An—

Ambler Asbestos (Century Brand) Shingle

roof is a silent and everlasting advertisement of the man who lays them. Such a roof must give him prestige and commend his work to that ever-growing body of home-builders who stop at nothing short of perfection.

You may specialize in churches, schools, garages or houses; it

makes no difference, you will serve the owner and yourself best by using Ambler Asbestos Shingles (Century Brand).

We have samples for your inspection. We shall gladly send these and trade prices. A line from you brings them.

Revolutionizing Building Methods

The Van Guilder Immediate Releasing Hollow Wall Machine makes continuous work on a building possible, no cessation of work. One handling of the material places it on the wall.

No matter how many angles or bays you want, you can take care of every cubic inch with this equipment. One Van Guilder Hollow Wall outfit is good for years. No need of buying expensive form lumber.

If you are interested in lowering the cost to you and your customers use the Van Guilder Hollow Wall Concrete Machines. Why not read more about the Van Guilder System? We will send catalog on request.

HAND RIP SAW

W. F. & JOHN BARNES CO.

71 Ruby St., Rockford, Ill.

Just what you've been looking for! —a combination Hollow Chisel Mortiser and Relisher

An entirely self-contained hollow chisel mortiser, that will carry chisels up to $\frac{3}{4}$ " square and make any larger or irregular mortise by overlapping the cuts.

Easy and simple to operate. No pounding or jarring. Every mortise perfect. No chips left to be picked out by hand, when you put your work on

the other side. Relishes out the tenon and bores away for that part which goes under the mold after you have completed the work on the sash stiles, rails and muntins.

Every carpenter and jobbing shop should have one of these machines.

Can You Imagine This?

70% of all the floor scraping done in Chicago last year was done with Triple "A" SPRING-DRIVEN Floor-smoothers.

Why?

In view of all other floor scrapers on the market there is bound to be a good reason for using this particular kind of a machine on so large a percentage of the work—more than double the work of all other machines put together.

In doing work there are two important points which a practical contractor always takes into consideration—his reputation for quality of work and the cost of labor; and where, in a building, does quality of work and cost of labor "cut more figure" than on the hardwood floors?

Seven years ago the Triple "A" SPRING-DRIVEN Floor-smoother was first introduced in Chicago, and today seventy per cent of all the floor scraping of this great city is being done "The Triple 'A' Way."

The majority of those in the contracting game have learned that it pays to "Triple 'A'" their floors, for by this process *only* can they be sure of maintaining those two essential points of

"High Quality and Low Cost"

Quality of work considered, the cost of surfacing floors "The Triple 'A' Way" is guaranteed to be lower than that of any other method.

ISN'T THAT A GOOD ENOUGH REASON?

If you are not already satisfied that you have the best machine in the world, you had better investigate this BETTER MACHINE.

Write now and we will tell you why this Machine does better work at less cost per square.

Up to the Wall and Into the Corners It Goes

Try This Scraper on Your Floors at Our Expense

Here's a Scraper that scrapes clean and smooth, in the corners, close up to the walls, and scrapes without those wavy lines so often caused by "chatter."

Our knife with double edge wears twice as long as any other scraper knife. Our adjustable handle, rubber tires and the way the weight is thrown on the knife are all exclusive features of the Stearns No. 10.

We don't ask you to "beware of other Scrapers," but we do ask you to accept this machine on a fifteen day **FREE TRIAL OFFER**, so you may "compare it with other Scrapers," for by test the Stearns is best.

There are fifteen days in which you can test its easy running, smooth shaving and sturdy qualities at our expense.

Write us about it.

Sold by dealers, direct from the factory or on fifteen days' trial. Particulars will interest you.

E. C. Stearns & Co.

400 Oneida St., Syracuse, N. Y., U. S. A.

"Pretty Soft for You"

Floor surfacing made easy. The Imperial Floor Sander does the trick. No aching back or tired knees. You can stand in the middle of the floor and finish the entire width of the room. Easily operated. A push and a pull does it.

No matter how the texture of the wood varies there are no wavy floors when the Imperial Floor Sander is used. It holds twelve sheets of sand paper which can be cut off, when worn, without removing binder. Has heavy felt cushions to prevent marring base boards.

Can be used also for removing varnish, resurfacing and waxing floors. Costs but \$5.00. Does the work of an expensive power machine. Any carpenter can afford it.

If your dealer doesn't handle the Imperial we will send one direct upon the receipt of \$5.00.

OAK: "America's Best Flooring"

Landlords offering houses for sale or for rent recognize the value of OAK FLOORING, and that is why they emphasize OAK FLOORING in their ads in newspapers. They know that OAK FLOORING is sure to attract a better class of tenants or buyers.

Nature has given OAK FLOORING that peculiar favor that appeals to the artistic as well as the demand for the distinctive and substantial.

The lady of the house finds OAK FLOORING an elegant expression of refinement, cheerful in color and capable of friendly harmony with other furnishings.

OAK FLOORING is always considered a good investment and grows old as gracefully as a Chippendale chair or a good Oriental Rug.

Write for booklet, "America's Best Flooring."

THE OAK FLOORING BUREAU, 1349 Conway Bldg., Chicago, Ill.

Steel "Stitches"

Every Few Inches

Columns which have staves simply glued together will surely open up. Columns which have any kind of a lock-joint are liable to open up. Columns which are glued under hydraulic pressure, where the staves are locked with a double V joint and sewed with cold rolled steel staples every few inches of their entire length *cannot* open up. And this is the way "Steel-Sewed" Columns are always made. Catalog explains the construction and shows many beautiful illustrations. Write for it.

AMERICAN COLUMN CO., Battle Creek, Mich.

"Acme" Brand

SELECTED
¾" x 1½" Quartered White Oak

FLOORING

Here is the greatest bargain ever offered in Quarter Sawed White Oak Flooring. Made of high-grade thoroughly kiln dried lumber, with modern machinery, by men who know how to make flooring that will save the carpenter many hours of hard labor in doing first-class work.

Mr. Milton Mathew, 814 Mulberry street, Marshall, Illinois, writes: "I laid some flooring last week from Chicago, and had to do twice as much work on it to get a finish as I did on the flooring I bought of you. I like that tongue and groove, it lays so easy and even."

Add one-third to the number of square feet to be covered and be convinced by sending a trial order. There is not one foot waste in a thousand feet, because it is all side and end matched. Shipments are made same day order is received, and you will find our flooring will save you many dollars.

THE BESSLER MOVABLE STAIRWAY

This is how it looks when in use

This photograph was taken in a bungalow. The owner wanted to use the attic for a bedroom, but was confronted with the usual stairway problem. The Bessler Movable Stairway solved it. He now has an additional bedroom without sacrificing space for a stationary stairway in the room below. The Bessler Movable Stairway is ready to solve those problems for you and help build you a reputation for progressiveness and expert knowledge of your trade.

Write us for booklet now.

This is how the stairway looks in ceiling when folded. Only a neat panel visible.

Cortright Metal Shingles Say "No" to flying sparks

FLYING brands and embers from adjacent fires cause an annual loss of many extra millions.

You can satisfy the demand for a highly fire-resisting roofing—and at the same time increase your revenue handsomely—by applying CORTRIGHT METAL SHINGLES.

Fire can't burn them, like prepared roofings and wooden shingles. They won't crack and fly off in the heat of a neighboring conflagration, like slate and tile.

And CORTRIGHT METAL SHINGLES give permanent protection against the elements as well as against fire. With a reasonable amount of care they last indefinitely.

Handsome in appearance, too—suitable for the most pretentious building—economical enough for the most modest cottage.

If you want to learn some vital facts about roofing, write for our booklet "Concerning That Roof."

The HESS Welded Steel Furnace for Separate Pipes and Registers.

National Defense and International Peace

What the Engineers are Doing

THIRTY thousand American engineers and chemists are making a card index survey of American industry so that it may be prepared for its vital part in defending the country, if need comes. The past eighteen months have taught us here in America what lack of industrial preparedness has meant to some of the countries now at war. These nations had the ships and they had the men; but when the hour struck, their factories were not able to furnish the colors with arms and shells and powder. Their factories were not prepared. And our factories are not prepared.

But it is not enough to draw a moral. In the United States five great Engineering Societies—Civil, Mining, Mechanical, Electrical and Chemical—have pledged their services to the Government of the United States, and are already working hand in hand with the Government to prepare industry for the national defense. They receive no pay and will accept no pay. All they seek is opportunity to serve their country, that she may have her industries mobilized for defense.

All elements of the nation's life—the manufacturers, the business men, and the workingmen—should support this patriotic and democratic work of the engineers, and assist them cheerfully when asked. *There can be no better national insurance against war.*

The Associated Advertising Clubs of the World, representing all advertising interests, have offered their free and hearty service to the President of the United States, in close co-operation with these five Engineering Societies, to the end that the country may know what the engineers are doing. The President has accepted the offer. The engineers have welcomed the co-operation.

This advertisement, published without cost to the United States, is the first in a nation-wide series to call the country to the duty of co-operating promptly and fully with the engineers.

Keeps Down Investment —Brings Up Profit

Builders of investment property desire the lowest possible cost because cost determines the profit on the investment.

Yet, at the same time, they must not sacrifice either quality or appearance. Give them what they want! Recommend the one wood that best serves their purpose—

North Carolina Pine

"The Wood Universal"

No wood at the price can equal it, whether used for interior or exterior work.

It possesses a rare beauty of grain; is splendidly responsive to paints, varnishes, wax, stains or enamels; is strong and durable and easy to work. And it is exceptionally low in cost.

Send for Free Reference Book

We have prepared a most instructive reference book on North Carolina Pine. It is not merely a compendium on North Carolina Pine but a most profitable help to every contractor and builder. Ask for Book B.

North Carolina Pine Association
Norfolk, Va.

Through the Paris Fire Unscathed!

THIS building which stands unharmed amid the ruins of the Paris, Texas, fire, dramatically emphasizes the fire-resistant properties of a Johns-Manville Asbestos Roof. W. A. Bills, Manager of the City Steam Laundry, owners of this building, writes us as follows:

"While adjoining buildings were burned to the ground, the Laundry stood the severest test that any building could be put to; blazing timbers and shingles were blown on to this roof only to die out without affecting in any way the roofing material."

J-M Asbestos Roofings provide a fire-resistant roofing for every purpose—J-M Asbestos Built-Up Roofing for flat roofs, J-M Asbestos Ready Roofing for sloping roofs and J-M Transite Asbestos Shingles.

These shingles are the safe and logical roofing for dwellings. They are fire-proof and practically everlasting—lighter and less expensive than tile or slate, yet meeting every artistic requirement.

J-M Asbestos Roofings are examined, approved, classified and labelled by the Underwriters' Laboratories, Inc., under the direction of the National Board of Fire Underwriters.

Johns-Manville will gladly advise with you, your architect or designer on any roofing question. Address all inquiries to the Roofing Service Department of the nearest J-M Branch.

ASBESTOS ROOFINGS

A Fire Resistant Roofing for Every Purpose

SEVEN ROOMS, BATH AND BASEMENT, TO COST ABOUT \$3,500.00. AYMAR EMBURY, II, ARCHITECT, NEW YORK CITY. OUR NEW HOME BUILDERS' BOOK SHOWS THE PLAN. ASK FOR IT.

Whether you are designing a small house for the man of moderate means, or one along more pretentious lines.

ARKANSAS SOFT PINE

will appeal strongly to either client because of its invariably pleasing appearance, durability and moderate cost.

Affording as it does a wide choice in the matter of figure and at the same time lending itself successfully to any desired decorative treatment, it is indeed a finishing material of all-round merit.

Arkansas Soft Pine is a non-resinous wood possessing a tough fibre, fine grain, and soft, lustrous texture, all of which make for well-balanced absorbing qualities. Stains or flat white are applied *direct to the wood* without the necessity of any preparatory filler or shellac, so that a uniform, even absorption of the color or white lead is assured.

Due to the definite non-resinous character of the wood, it positively will not discolor the white enamel from underneath, nor dim the luster of waxed or varnished finishes.

Our finished samples will bear out the foregoing statement. We'll send them on request. Address Dept. R.

Arkansas Soft Pine is trade marked and sold by dealers. See that yours supplies it. He can.

Manufactured under U. S. Patent No. 1,060,543

The Latest Evidence of Morgan Leadership

In addition to the features of construction which have always made Morgan supreme in the veneered door field, Morgan Doors will in the future be built exclusively with the Wedge Dowel Construction. That means additional insurance against any possible annoyance or trouble. It means

Doors That Can Never Come Apart

The Wedge Dowel made of hard wood is slit obliquely at each end as shown in illustration above. When clamped into place, the wedge formed by the slits is driven into the dowel, expanding the sharp ends and driving them into the soft White Pine core, locking stiles and rails together in a vise-like grip.

No pockets are left to gather glue at the ends of these wedge dowels. Instead the glue is forced along the dowel, thus making a perfect bond between dowel and core.

Morgan Doors are the only hard wood doors made with Wedge Dowel Construction.

Think what this improvement means to

Doors

Already safe in their leadership because of the exclusive All White Pine Core, this latest forward step in the building of Morgan Doors means even greater satisfaction for the owner, and means greater assurance to you that once a Morgan Door is properly hung it will give perfect service without the necessity of constant retrimming and rehanging.

Now more than ever Morgan Doors are the doors that safeguard your reputation as a high-class contractor.

Stained with Cabot's Shingle Stains
Upjohn & Conable, Architects, N. Y.

The Shingles and Timbering

of this beautiful Old-English residence are colored and preserved with

Cabot's Creosote Stains

The shingles are warmer than English tiles, and the coloring is much softer and richer, owing to the texture of the wood and the deep velvety tints of the stains. The stained timbers, in old smoky browns and dark grays that bring out the grain, harmonize perfectly and weather out beautifully. Cabot's Stains are artistic, inexpensive, lasting, and the Creosote preserves the wood.

Cabot's Quilt

30 Times Warmer than Building Paper

Quilt is a thick matting of dead air spaces and one layer is warmer than 30 layers of common papers. Used at the South Pole by Scott and near the North Pole by McMillan, with perfect success. The best sound-deadener.

You can get Cabot's Stains and Quilt all over the country. Send for samples and names of nearest agents.

Siding

Section of Outside Wall of House, Showing Wool
Between Studding.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

The Building Age

NEW YORK, JUNE, 1916

General Appearance of the Residence of G. F. Allum at Wheaton, Ill., and Designed by Architect Albert E. Colcord of Chicago, Ill.

IN the Middle West the sun parlor has rapidly come to the front as an attractive feature in modern house and flat building construction. This is especially true in Chicago and its suburbs, and many instances could be cited where carpenters and builders have been called upon to remodel houses along this line built five or ten years ago. Porches of this character of the enclosed type are unquestionably more in vogue than those having no protection whatever from the elements, and this means that the occupants are able to utilize them the year round. Where such buildings are heated by steam or hot water comparatively little trouble has been experienced in supplying sufficient radiation to offset the additional heat losses incurred by the installation of so much extra glass surface. Some sun parlors are built with brick sides and a glass

front, but investigation has shown that those exposed on all sides are the most popular.

This improvement has therefore inaugurated the establishment of an additional cosy room which is not only an architectural feature, but one that the owner fully appreciates. Irrespective of climatic conditions, it affords an excellent view in three different directions. Of course, these sun parlors vary in their dimensions, but a typical one may be said to have sufficient proportions to house two or three chairs and a small table. Specifications invariably call for direct communication of the sun porch with the living room, and where a southern exposure is possible, a well arranged home is flooded with an abundance of natural light during the entire day.

Among the most attractive suburban homes around Chicago having this interesting feature as

well as other pleasing points in the exterior decorative treatment and interior arrangement, are those to be found in Wheaton, Ill. The one here illustrated is a practical example of what may be accomplished in the Middle West for an expenditure not exceeding \$5,000, involving the construction of a home

ination reveals the fact that particular attention was paid to every detail, and the trellis work provided around the front and rear entrances, together with the flower box directly over the main entrance, is evidence of the truth of this statement. The use of a smooth, white stucco as a finish coat creates a

A House at Wheaton, Ill.—Detail of the Main Entrance

of ample proportions to accommodate the needs of an average family.

It will be observed from the pictures of the exterior that the use of wooden columns and the introduction of pergola effects has been carried out with a harmony that adds materially to the artistic appearance. This effort has been brought to a successful conclusion without increasing the cost of production to an alarming extent, resulting in an extremely well balanced building. A careful exam-

uniform color scheme throughout which blends with the green shingles and the dark red brick.

The house faces east, and the sun parlor has a southern exposure. The building is approximately 36 ft. long and 22 ft. wide, while the sun parlor is 10 ft. by 15 ft., being exposed on all sides.

The front entrance gives access to a small vestibule, in which twelve coat hooks have been provided. An inner door separates the vestibule from the hall, and to the right and left of the latter are to be

found the dining room and living room, respectively.

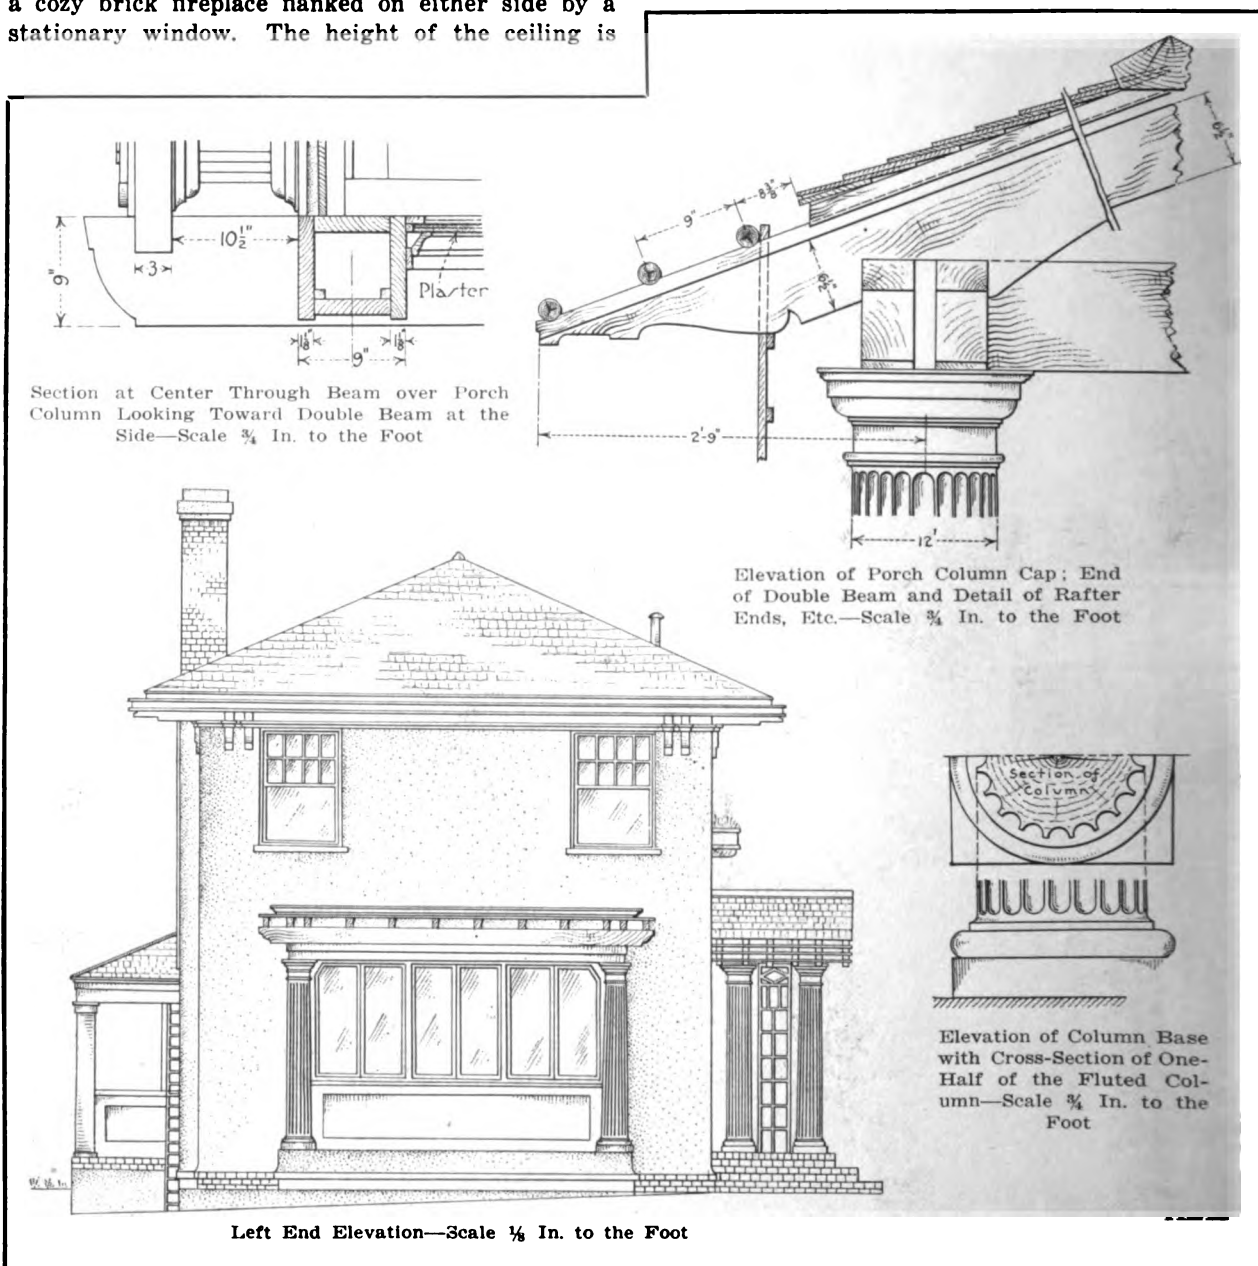

The stairs leading to the upper quarters are splendidly lighted by three long narrow windows. These are revealed in the exterior view taken from the rear, and the reader may pass on the advantages of these facilities by focusing his attention directly over the rear entrance. It will also be noticed on the first floor that a small recess to the right of the stairs has been provided for a telephone table and a chair.

The living room is 14 ft. wide and 20 ft. long, extending the full width of the house. At one end is a cozy brick fireplace flanked on either side by a stationary window. The height of the ceiling is

side and six facing south. A radiator in one corner makes this room a comfortable one during the colder months.

At the northeast corner of the residence is the dining room, 14 ft. 6 in. long by 11 ft. wide. There is a built-in buffet and in the recess above are three windows.

The kitchen, adjacent to the dining room, has its fixtures distributed around three sides, leaving plenty of room in the center in which the domestic may operate. A large built-in cupboard for china-

Miscellaneous Constructive Details of a House at Wheaton, Ill.

8 ft. 9 in. The mantel above the fireplace projects $9\frac{1}{2}$ in. from the wall and is $3\frac{1}{2}$ in. thick. The hearth is built from 6-in. quarry tile.

The sun parlor is separated from the living room by a door having eighteen panes of glass, three to a row. When the sun is shining, therefore, a steady stream of light comes through even as far as the hall, brightening this section of the house very considerably. There is installed in the sun parlor a total of fourteen windows, distributed four to each

ware has beneath it seven drawers, for a variety of purposes. Next to it is an enameled iron sink, with draining board, and reference to the floor plan will show the location of the gas range and a "Hoosier" kitchen cabinet. In an adjoining entry is a large cupboard, with four shelves, and space for an icebox.

On reaching the hall on the second floor a large linen closet confronts the visitor. The arrangement on this floor includes three bedrooms and a bathroom. The largest of these has the same dimen-

View in the Dining Room Looking Toward the End Containing the Built-in Buffet

A House at Wheaton, Ill.—The Living Room with Sun Parlor at the Left

sions as the living room and is directly over it. A roomy closet, 4 ft. 6 in. wide and 7 ft. long, is lighted by a window on the east side. The two remaining bedrooms are situated at the northeast and northwest corners, and are respectively 9 ft. x 11 ft. 6 in. and 8 x 13 ft. The bathroom is 6 ft. wide and 8 ft. long, replete with modern fixtures arranged on one side.

The footings and basement walls of the house are of concrete, composed of one part Portland cement, three parts torpedo sand and five parts crushed stone. Anchor bolts are built in the top of the wall for securing the sills on which the studding rests. The outside of the basement walls has been plastered with waterproofed Portland cement.

A concrete floor in the basement, is laid on a

trimmers are double, well framed and spiked together.

The stud partitions are No. 1 yellow pine and all bearing partitions have plates top and bottom.

All rough underflooring is No. 2 common 6-in. fencing, dressed on one side, laid close and nailed double to every joist. On the first floor this is covered with heavy tar paper on which is placed the finish floor of $2\frac{1}{4}$ -in. face white oak except in the kitchen and rear entry where it is $2\frac{1}{2}$ -in. face maple. The second story underflooring is covered with one layer of H. W. Johns-Manville Co's Keystone hair insulator, with red building paper on one side and felt paper on the other, laid with the latter side up. The finish floors are of white oak including that of the bathroom.

A House at Wheaton, Ill.—View in the Kitchen Showing Gas Range, Sink and Cabinet

$3\frac{1}{2}$ -in. foundation and consists of one part Portland cement, two parts Lake Shore sand and four parts crushed stone. The half-inch finish coat contains equal quantities of Portland cement and torpedo sand. The work is laid true and to an even surface, and rests on a 4-in. bed of cinders.

The joists, girders, etc., are of No. 1 yellow pine, set 16 in. on centers. The first and second floor joists are 2 x 10 in., the ceiling joists and the rafters are 2 x 6 in., the valleys are 2 x 8 in., the studding and plates 2 x 4 in., and the ridges 1 x 8 in. The bridging is made of sound 2 x 4 in. material. Both tiers of floor joists have two rows of bridging the entire length of the house. The rafters have a 2 x 6-in. collar beam for each rafter. Headers and

The sides of the house are covered with 6-in. matched fencing, dressed on one side, over which was placed tar building paper. Crimped metal furring strips were then attached and "Kno-Burn" expanded metal laths fastened on horizontally, so that the length of the sheet runs across the furring. The dip of the strand is set down and inward to form a perfect key. The edges of the sheets are lapped $\frac{1}{2}$ in., and the lath is applied to the furring strips every 4 in., using $1\frac{1}{2}$ -in. staples.

In producing the stucco finish to be seen in the pictures of the exterior "Stonekote," made by the Garden City Sand Co., Chicago, Ill., was used throughout, it consisting of the company's waterproofed plastic marble float application and is three-

coat work. The exterior surface of the chimney stack was treated in a like manner.

The various roofs are covered with Star A white cedar shingles, securely attached with galvanized

The exterior woodwork of the house is painted two coats, exclusive of the priming coat. All first floor finish received two coats of varnish, rubbed to a flat finish with pumice stone and oil. The door and window sill in the bathroom were stained for mahogany and then varnished two coats. The second floor birch trim received three coats and one of white enamel. The bathroom has four coats of white enamel on the walls and ceiling, no paint being applied beneath the enamel.

The oak floors are filled light and have two coats of Pratt & Lambert's floor varnish. Maple floors received two coats of linseed oil. One coat was applied as soon as the floor was laid, while the final application was given on completion of the building. The inside of all sash is painted or stained to match the room which it faces, two coats of varnish being applied to the stain.

The bathroom fixtures include a "Superior X" closet, a "Norwood" lavatory and a 5-ft. "Corona" bathtub, of types made by the L. Wolff Manufacturing Co., Chicago. Installed in the basement is a two-part Durostone laundry tray, 33 in. high. The kitchen sink is 20 x 30 in., and is 33 in. high.

The sheet metal work is made of No. 26 gage

A House at Wheaton, Ill.—View in One of the Bedrooms with Glimpse of Stair Hall at the Right

iron nails and exposed $4\frac{1}{2}$ in. to the weather. Before being applied they were dipped three-quarters their length in Cabot's light green creosote stain.

The finish work in the house includes wood cornices for the living and dining rooms, sideboard, china closets, linen closets, mantel shelves, medicine cases, cabinet with drawers in the rear entry and kitchen, and picture molding for each room.

The entire first floor is trimmed in red oak, and the second floor has birch trim. The doors are of white oak on the first floor and birch on the second. Inside doors are $1\frac{3}{4}$ in. thick. The front and vestibule doors and those in the rear kitchen and basement are $2\frac{1}{4}$ in. thick. All closets are equipped with two rows of 10-in. shelves. Beaded strips are extended all around 4 in. wide, and furnished with cast iron wardrobe hooks every 8 in., attached with screws.

The walls and ceilings of the first and second floors are plastered two-coat work. The living and dining rooms, vestibule and hall have a gray sand finish, while the balance of the house has a plaster of paris smooth white finish. The brown coat consists of clean sharp lake sand and live quick lime, well slacked and strained, and good cattle hair, well picked apart and mixed with a good quality fiber.

Rear View of the House at Wheaton Showing the Sun Parlor and Outside Chimney

American Ingot iron. The downspouts from the main roof are 5 in., and are carried to the sewer. They are secured to the building by means of metal rings, leaving a space of 2 in. between the wall and

the spout. One downspout has been installed to take care of drainage from the sun parlor roof. The flower box on the front of the building is lined with American Ingot iron, and three drains are provided, as shown on the accompanying elevations.

In the basement is to be found a Detroit Jewel No. 12 B. gas water heater for supplying hot water to the fixtures in the summer time. Proper connections have been made to a 40-gal. tank.

A cistern has been installed in the yard to accumulate soft water, and the plumbing system is so cross connected that either soft water or city water may be used.

Reference to the picture of the rear of the house shows a coal chute beneath the west side of the sun parlor, made by The Majestic Co., Huntington, Ind.

The building is heated by a hot water system, there being a total of 612 sq. ft. of direct radiation, distributed into 11 units. The living room and the main bedroom have radiators installed at the east and west ends, as indicated on the floor plans. The remainder have but one radiator. The equipment is guaranteed to heat the building to a temperature of 70 deg. when the temperature outside registers 10 deg. below zero. A Spencer boiler has been provided having a 1200 sq. ft. rating and made by the Spencer Heater Co., Scranton, Pa. A Honeywell system of heat regulation has also been installed.

The building is piped for gas and wired for electric lighting. In the latter connection it has been the practice to install a fixture in the center of each room, but in the living room and bedrooms brackets have been provided around the walls at advantageous points.

The house here described is occupied by G. F. Allum, 704 Gary Avenue, Wheaton, Ill. Plans and specifications were prepared by Architect Albert E. Colcord, 117 North Dearborn Street, Chicago, Ill., and the construction work was carried out by A. Johnson of Glen Ellyn, Ill.

Value of Slate Sold in 1915

The total value of slate of all kinds sold in the United States in 1915 was \$4,958,515, according to the United States Geological Survey. This was a decrease of 13 per cent compared with 1914. The sales of roofing slate in 1915 were 967,780 squares, valued at \$3,745,934, and of mill stock 4,576,112 square feet, valued at \$819,672. Blackboard material and school slates decreased 31 per cent.

Several producers have reported to G. F. Loughlin, of the Geological Survey, that during the last three months of the year conditions began to improve and that early in 1916 prices for slate of all kinds were more encouraging than at corresponding times for several years. At present many of the quarries can greatly increase their output to keep pace with any increase in demand.

In Maryland and New York there were substantial increases in the value of the slate sold, and in Virginia a small increase; in the other States—Maine, New Jersey, Pennsylvania, and Vermont—there were decreases.

The total number of operators, which had decreased from 171 in 1913 to 157 in 1914, continued

to decrease in 1915 to 148. Virginia was the only State in which the number increased—from 7 to 8. Of the States producing roofing slate, Maryland gained not only in quantity and value, but the price per square decreased in each State. Pennsylvania and Vermont, which together yielded more than 86 per cent of the total value of roofing slate, decreased in quantity, value, and price per square. Only Maine, Pennsylvania and Vermont reported sales of mill stock in 1915, and in all these States both quantity and value decreased.

The value of slate exports, which was \$226,413 in 1913 and \$139,125 in 1914, was only \$46,137 in 1915, the lowest recorded since 1895. England, which has heretofore been the largest user of American slates, did not import any in 1915; neither did Belgium, Denmark, Germany or the Netherlands. The failure of the United States to export a large amount under these conditions indicates a world-wide decline in building operations during 1915.

Next to the United States, Great Britain and France are the chief slate-producing countries, and Belgium ranks fourth. Other countries reporting an output of slate are India, Germany (Bavaria), and Canada. As all these countries were directly or indirectly involved in the European war during 1915, both their production of slate and their demand for slate doubtless greatly decreased. Canada's production, according to John McLeish, of the Canada Department of Mines, decreased from 1075 squares, valued at \$4,837, in 1914, to 397 squares, valued at \$2,039, in 1915.

Color Absorption of Light

In an interesting and instructive article dealing with hospital construction, Oliver H. Bartine tells in a recent issue of *Building Management* that recent tests by illuminating engineers show that light is absorbed by walls of different colors as follows:

White	18%
Chrome yellow	38%
Orange	50%
Plain deal	55%
Yellow	60%
Pink	64%
Emerald green	82%
Dark brown	87%
Vermilion	88%
Blue green	88%
Cobalt blue	88%
Deep chocolate	96%

Coating for Blue Print Paper

As a result of the great increase in the price of potassium-ferri-cyanide, or red prussiate of potash, which is extensively used as a coating material for blue-print paper, an economical method of preparing the substance has been devised by the U. S. Department of Agriculture. Particulars relating to this method have been sent out by the Department accompanied by a blue print of the apparatus for use in connection with the preparation of potassium-ferri-cyanide from potassium-ferro-cyanide.

Some Aspects of Modern Shingling*

The Straightedge, the Chalkline and the "Gauge and Hatchet" Methods of Laying Shingles

BY EDWARD H. CRUSSELL

WE will now consider some of the methods of laying shingles. One of the oldest methods is that in which a straight-edge is used. At first the workman used any straight-edge that happened to be handy, and then some one thought of making a straight-edge the exact width the shingles were exposed to the weather. This did away with the measuring for each movement of the straight-edge, as all that was necessary was to keep the lower edge of it flush with the lower edge of the course just laid, and the upper edge would then be in line for the next course. The straight-edge was

used. It is faster than the straight-edge method, but has many disadvantages compared with the next method to be considered, which is usually known as the "gauge and hatchet method."

This is the method used by the professional shinglers in the Western States, of whom some wonderful stories of big day's work have been told.

The hatchet used is either the lathing hatchet, Fig. 9, or the boxmaker's hatchet, Fig. 10—usually the latter because frequently the shingler changes his profession to that of boxmaker during the fruit season. One will *never* see the professional shingler

Fig. 9—A Lathing Hatchet

Fig. 10—A Box Maker's Hatchet

Fig. 11—The Ordinary Shingling Hatchet

Some Aspects of Modern Shingling—Various Kinds of Hatchets

usually fastened in place, and quite frequently the shingles were put on by two workmen, one laying and the other nailing. This is almost the slowest of all methods of laying shingles, though it may still be found in use.

The next method was that of the chalk-line. In the original method a line was snapped for each course, but eventually some one discovered that if two lines were snapped it was possible to carry two courses at once because the second line could be easily seen through the spaces between the shingles of the first course. This method is still extensively

used with the hatchet that is designated by the tool manufacturer as a shingling hatchet. This instrument is pictured in Fig. 11, for no other reason than that the novice may know what it looks like and fight shy of it.

Fig. 12 shows a combined hatchet and gauge. This has been placed on the market in the last few years, and although the writer has never used one, it appears to him to be a satisfactory tool.

Fig. 13 shows the hatchet gauge that is in general use, and Fig. 14 its appearance when applied to the hatchet. This gauge is about $\frac{3}{4}$ in. diameter, with a slot $\frac{1}{8}$ in. wide. It can be applied to any of the box or lathing hatchets, and of course can be

*Copyrighted, 1916, by Edward H. Crussell.

adjusted to more positions than the gauge shown in Fig. 12, which is an advantage when the width of the courses must be varied, as in finishing up at the ridge or spacing between window heights on the side walls.

This ease of adjustment is also a disadvantage, as the gauge is liable to move from position with the continual use of the hatchet, and to prevent this movement something more than the set screw is needed. Probably the best method is to drill a small depression in the hatchet for the end of the set screw at those points where the gauge will be most frequently used and keep careful watch of the gauge when using it in other positions. The gauge can be quite firmly fixed by making the set screw half a turn too tight before applying the gauge to the hatchet and then driving it on with a hammer from the upper edge. This method, of course, takes away some of the ease of adjustment.

And now having distributed our shingles, built our seat and fixed our hatchet, we are at last ready to start work. The first course of shingles usually projects over the edge of the roof boards about 1 in. and must always be a doubled course or two thick-

Fig. 12—A Hatchet with a Fixed Gauge

Fig. 13—The Hatchet Gauge

Fig. 14—The Hatchet Gauge in Place

Some Aspects of Modern Shingling

nesses of shingles. It may be laid by first fixing a shingle at each end of the roof with the correct projection and then stretching a line to which the butts of the other shingles are laid. On a long roof it may be necessary to fix one or more intermediate shingles, to which the line is also fastened, and sometimes on old buildings that are out of line it may be necessary to adjust these shingles by eye instead of giving them all an equal projection over the roof boards.

Each shingle is fastened with two nails, which are driven about 2 in. above the line of exposure so that they may be covered by the following course. Some authorities advise placing the nails so that they may be covered by two courses. This would mean that with shingles laid $4\frac{1}{2}$ in. to the weather the nail must be driven $9\frac{1}{2}$ or 10 in. from the lower edge, and the greater the exposure the further up must the shingle be nailed. In the opinion of the writer, any advantage gained by this method is more than offset by the tendency the shingles have to curl and buckle when nailed so far from the butt. It is better to nail them lower down and then be careful that none of the joints in the course above come directly over a nail. Shingles nailed at the lower position are twice as securely fastened as

those nailed at the upper. This is easily proven, because the nails driven in the course that is being laid go through the course below in about the same place as is advocated by those who wish their nails covered with two courses of shingles.

The joints of the shingles should be broken for three courses, which means that no joint in any one of three courses should be directly in line with another. To accomplish this result with random width shingles is not so difficult as might be supposed. Each joint should be broken at least 1 in., which means that no joint in any course should be nearer than 1 in. to a joint in the courses next to it.

We have already stated that the professional shingler often prefers to get right on to the roof instead of working the first courses from a scaffold, and Fig. 15 is a photo showing one of these fellows just commencing his job. It will perhaps be noticed that he breaks open his bundles as he uses them,

(To be continued)

"Floor for Doctors" A New Skyscraper Wrinkle

An interesting architectural development in connection with recent office building construction is the setting aside of a floor especially equipped for the exclusive use of physicians, surgeons and dentists. A feature of this kind is found in the ninth floor of the Third National Bank Building in Springfield, Mass., which was designed and erected by Hoggson Bros. of New York City, who have made an extensive study of the specialized building question. The floor in the building named has been fitted up as offices for one, two, three or any number of associated practitioners with operating rooms, laboratories and rest rooms, as may be required, opening from the reception room used in common.

Here the associated doctors may have the combined service of a staff of assistants consisting of nurses, a secretary and a maid, which under the ordinary arrangement of offices is often prohibitory by reason of the expense. There is provided gas, electric light and power, compressed air, and special basins with hot and cold water under pedal control. In each dental laboratory are suitable workbenches, compressed air, gas, electric light and power outlets, hot and cold water and other necessary devices and equipment.

Another Co-Operative Apartment House

Operations have just been commenced upon the construction of a fifteen-story co-operative apartment house and studio building on the corner of Sixty-seventh Street and Central Park West, the cost of which, including the land, will approximate \$1,000,000. Efforts will be made to create a record in constructing the building so that it may be ready for occupancy by Oct. 1 of the present year. The work will be done by the William J. Taylor Company, 5 East Forty-second Street, New York City, which has erected all the studio buildings in Sixty-seventh Street and is now engaged in the erection of the Hotel des Artistes, on the north side, next to the corner. The new project is the first important improvement on the south side of Sixty-seventh Street and is also the first of the studio buildings to have an unobstructed park view.

Features of Roof Gutters and Leaders*

Their Character—Shape of Pipes—The Drainage—Forms of Gutters for Hanging on Eaves

IF the plumber is the householder's personal devil his first entrance to the home must have been by way of the gutter and rain pipe. The English use of "leads," for flat roofs, and of "plumber" (or lead worker) for roofer, points to the progress of lead from roof drains to drain pipes within houses. Doubtless it was the truly demoniac behavior of joints stopped with lead in letting in rain which first gave the wretched plumber the reputation he has never since lived down.

Development of Plumbing

But the development of external and internal plumbing has been in quite divergent directions. Inside, the proudest spot of the house is likely to be the gleaming nickel and porcelain of the sanitary equipment, grown from "exposed" to what might be called "displayed" plumbing; while outside the tendency is all toward disposing gutters and drain pipes and spouts as unostentatiously as possible. The gargoyle has fallen into innocuous desuetude.

But why gutters or rain pipes at all? The principal reason is clearly the protection of walls from discoloration, or disintegration from the dissolving acids which may be contained in the rainwater. Then the foundations and flower beds or lawns need to be sheltered from the dropping or spattering from the edge of the roof.

The character of gutters and leaders depends first of all on the type of roof itself, whether flat or pitched. The main motive of the pitched or inclined roof is, of course, to shed water, ice, or snow. It is usually made up of small units such as shingles or tile, articulated for expansion and contraction in extreme variations of climate. If metal roofing is used it must be articulated for expansion both of itself and of the underlying roof structure. For flat roofs lead and copper have been given up for asphalt and pitch, which, if somewhat protected from oxidation, have a long life of viscosity and consequent impermeability. The better roofs of this type are also covered on top by brick or tile.

Disuse of Lead for Gutters and Pipes

Why have we not gone on using lead for gutters and rain pipes, as in the days when leadworking was a traditional art, and ornamental gutters and leader heads the pride of the house owner? First of all, because of the cost, which would now be prohibitive. Moreover, lead is extremely heavy, and pipes burst under sag or freezing, and are corroded by time. Other materials available are solid copper, and thin sheet-iron or steel protected by paint, tar, tin, zinc, or copper coating. But no metals are immune from corrosion. Rainwater carries dissolved dust and acid gases—sulphuric acid from coal smoke and carbonic anhydride from the air—and

these will attack lead, copper or iron, forming sulphates or carbonates, in addition to the oxides formed by the oxygen of the air, the action of the whole accelerated by dampness.

Materials Governed by Cost

The practical choice of material is governed by the relative cost, together with relative immunity from attack, and the conclusion is that we take either galvanized iron (zinc-covered sheet iron) or solid copper. Zinc, as regards iron, is electro-positive, whereas copper, tin, lead and nickel are electro-negative. That is, if a minute pore reveals the iron under its zinc coating, the zinc in its dilute acid bath of rainwater, which sets up electric current, goes into solution and particles rush over to this exposed point of iron and unite with it, thus continually recreating the continuity of the coating. The other metals, being electro-negative, retreat, on the contrary, from the edge of any such exposed point, the iron going into solution and being deposited in its turn on the tin and the point going deeper. In simpler terms, tin, copper and nickel-plate are ruled out as drainage pipes because of pitting; zinc prevents pitting.

When Price Is Not a Consideration

If price had not to be considered, nickel or copper would be an ideal material, because nickel is to copper as zinc is to iron. But in present conditions solid copper and galvanized iron are the practical choices. Galvanized iron has a life of six to eight years. Painted outside, the life of galvanized iron would be increased 50 per cent., but an inside coating would very soon be washed and scraped away. Solid copper resists disintegration indefinitely, because the first surface corrosion adheres fast and itself forms a hard, protective coating.

The initial cost of copper is three times that of galvanized iron, including labor of erection; and this difference is somewhat increased by the practice of having copper work specially designed for each building, which both means more work and more material; while galvanized iron is used mostly in ready-made units. Fifty dollars will buy the gutter and leader equipment for the average house.

Cypress for Gutters

Cypress wood for gutters, if well chosen and seasoned, has a long life; but the difficulty is to secure it so that it will not twist, or the joints open, in stress of freezing, drying out, etc. For a damp, warm climate, such as that of our South, it does very well.

Masonry in the form of a dish-shaped channel in the cornice is also occasionally used for gutters.

As to the shape of pipes, it is clear that the circular section will carry more water for a given weight of metal than the square. The square form is,

*Benjamin A. Howes in *Country Life in America*.

however, of better appearance against a wall, both as regards its own shape, and in fastening. Each section may carry a lug by which it is fastened to the wall. The next upper section fits inside it, and the whole joint is covered by a ship-shape wall fastening in the form of a metal band. Few people think that such a leader is anything but a single integral tube. This arrangement is especially desirable in that it allows easy inspection or repair of parts, and provides for expansion or contraction of the sections, and movement of the walls. Expansion is further met by longitudinal corrugations, as well as by the square form itself, which can take care of even a solid ice formation without breaking. The fact that cast-iron pipes cannot thus expand is one reason for not using them for leaders, except where they run down inside the building.

Setting Leaders

All leaders should set into a length of cast-iron pipe slightly above the ground level; first, because a thinner metal leader will rust from continual dampness there; and secondly, because the greater mechanical strength of the cast-iron pipe protects against blows, such as that of a lawn mower. The leader should on no account be free at its lower end, for the spouting of water is destructive to grading, may form ice on paths in winter, or even back up in the leader itself by the formation of an icicle.

Failing ability to connect with a public sewer or drainage system, these rainwater drains, in the case of small buildings on sandy soil, will take care of themselves at 15 or 20 ft. away from the house, if turned into a dry well; in sandy strata two buried barrels full of stone or gravel will serve. Otherwise a dry well of larger capacity will be required, or better still, the drain can be made to discharge at the surface at some convenient place. It is not desirable to turn rainwater into a private sewage disposal system, where it is liable to wash out the raw sewage.

Gutters for Hanging on Eaves

Gutters may take various forms for hanging on eaves. Far the simplest is the semicircular gutter, with edges rolled for stiffness, hung under the eaves with heavy galvanized iron or cast bronze brackets. Or there may be one gutter inside the other; the inside one tipped to bring water quickly to the leader opening, the outside perfectly horizontal to preserve appearance. In no case is the gutter concealed in the roof structure desirable. It is difficult to make right in the first place, and almost impossible to repair, and it is dangerous because of the great variations of its own expansion and contraction from that of the roof structure proper. The simple hung gutter is preferable, especially as it may be made to look like part of the cornice.

For flat roofs the leader head should be enlarged at the point where it leaves the gutter, to provide against the clogging of sticks. Otherwise the enlarged head may be placed against the wall, with a gooseneck leading down to it. Sometimes a copper wire basket protects the leader opening.

It requires more than a century for a cedar tree to grow large enough to yield a thirty-foot telephone pole.

Schedule of Ventilation Standards

In the report of a committee appointed by the American Society of Heating & Ventilating Engineers to prepare a schedule of minimum ventilation requirements applying to public and semi-public buildings, we find the accompanying table which is likely to prove of interest to architects and heating engineers. The requirements are based on minimum floor space per occupant, minimum cubic space per occupant, minimum hourly air supply per occupant, rules governing air distribution, temperature regulation, heat sources, provision for mechanical exhaust where required, reduction and control of excessive temperature and humidity. The standards set by this committee are as follows:

Class of Building	Floor Space, Sq. Ft.	Cubic Space, Cu. Ft.	Air Supply, Cu. Ft.	Temperature Range, Degr. F.
Theaters	6	90	1,200	60—72
Auditoriums	6	90	1,500	60—72
Court Rooms	6	90	1,500	60—72
Primary schools	12.5	150	1,800	60—72
Schools and colleges	15	18	1,800	60—72
Factories	25	250	1,500	60—72
Manual training	25	250	1,500	60—72
Work rooms	25	250	1,500	60—72

Air Distribution.—The distribution and temperature of the air supply to be such as to allow the maintenance of required temperature without uncomfortable drafts or any draft lower than 60 deg. F. The carbon dioxide determination to apply as a test of proper air supply and distribution. The maximum allowable carbon dioxide content not to exceed ten parts in ten thousand parts of air.

Temperatures.—The temperature of air in occupied rooms in all classes of buildings to be not less than 60 deg. F. nor more than 72 deg. F. during periods when artificial heat is required.

Heat Sources.—Any source of heat which does not contaminate the air supply nor conflict with local requirements of the departments of health, fire, electricity, or building, may be used both for warming air supplied ventilation and for heating by direct radiation.

Mechanical Exhaust.—Where required on account of dust, fumes, gases, vapors, fibers, or other impurities being generated or released, mechanical exhaust systems are to be provided of proper design and to be operated as required to remove such impurities.

Excessive Temperature and Humidity.—Where excessive temperature or humidity occurs as a result of the location or the nature of the work done, or processes employed, provision shall be made for the reduction and control of such excessive temperature and humidity.

Unify Building Laws

Believing it evident that the peninsula south of San Francisco is facing a great building boom, the two trustees of Burlingame, Hillsborough and San Mateo, Cal., have arranged for a joint meeting to provide for the enactment of uniform building ordinances.

Arrangement of Sliding Partitions

The Accordion Folding Door Partition Which Is One of the Three Principal Types—Various Details

By E. J. G. PHILLIPS*

THE accordion folding door has proved itself a valuable asset to the up-to-date church and Sunday-school room. Its use has made the separate class room possible with the minimum expense and it can usually be applied to old buildings with little difficulty as well as to new buildings. The large number of churches which are being remodeled and fitted with this type of door bear witness to the foregoing statement. Fig. 10 is the plan of a large Sunday-school room showing the extensive use of this type of partition. The interior view, Fig. 11, showing a number of accordion partitions, gives a good idea of the appearance of the doors in actual use.

All of the doors can be folded to one side or they may be divided at the center and half the doors folded to each side of the room, as in Fig. 12.

Fig. 10—Plan of a Large Sunday School Room

View Showing Accordion Doors Closed

Fig. 11—The Use of a Number of Accordion Partitions, the Doors Being Shown Open

Arrangement of Sliding Partitions—Use of Accordion Doors

When opened, the doors fold compactly against the wall and no pocket is required. A half door is required adjoining the jamb toward which the doors fold. By reference to Fig. 17 it will be noted that where all the doors fold to one side one half door is required, but when divided at the center and folded toward both sides two half doors are necessary. A sufficient number of doors should be used so that no door will exceed 3 ft. in width. The half door, so-called, is really less than half the width of

door, thus allowing the doors to fold as compactly as possible, and it is based upon the use of a well-known make of door hangers.

Width of full-size doors =
Clear width of opening "H" + "B" (from table Fig. 13)
number of full size doors + 1/2

Width of half doors = $\frac{\text{width of full size door "B" }}{2}$

If the doors are to fold toward both sides, as in the upper plan, Fig. 12, consider the distance from the center line of opening to jamb, as clear width

*Engineer Richards-Wilcox Mfg. Company.

of opening *H* and divide by the number of doors which are to fill this space.

As an example, consider an opening 12 ft. wide, i.e. the space which the doors actually occupy with four full size doors $1\frac{3}{4}$ in. thick and using loose pin butts. Adding *B* from the table, which is $1\frac{1}{8}$ in. to 12 ft., equals 12 ft. $1\frac{1}{8}$. or $145\frac{1}{8}$ in. This divided by $4\frac{1}{2}$ equals $32\frac{1}{4}$, the width of each full size door. Dividing this by 2 equals $16\frac{1}{8}$ in. Subtracting $1\frac{1}{8}$ in. from $16\frac{1}{8}$ in. equals 15 in., the width of the half door.

All the full size doors must be exactly the same width, and the sides must be exactly parallel and at right angles with the top and bottom. Special care in regard to these details, as well as in locating all the butts so the hinge pins will be exactly the

in the sizes listed are considered suitable for ordinary wood doors of the given thickness, but for extra high doors or doors constructed of materials which considerably increase their weight, a larger size door hanger should be used, and this necessitates the use of larger butts, as given in the table in the line corresponding with the hanger to be used. In calculating the width of the doors, the quantity *B* should be taken from the same line in the table in which the size of butt is given and not from the line which gives the thickness of the door.

Flat surface hinges may be used if desired so long as the size door hang listed for given thicknesses of doors is followed and the hinges are of such dimensions that the space between the doors when folded is not less than that given in the table, Fig. 13, for tight pin butts. The general run of surface hinges will meet this requirement. In using larger hangers than those listed for the dif-

Fig. 13—Table of Sizes and Distances for Placing Tight and Loose Pin Butts with Thickness of Doors

Arrangement of Sliding Partitions—Use of Accordion Doors

same distance from the edge of the door, will help greatly in producing a set of doors which will operate in first-class manner.

The use of doors having tongue and groove meeting stiles is recommended, as this will produce a much tighter partition. Doors of any standard thickness may be used, this depending upon their size and other special conditions.

Loose pin butts are generally used to hinge the doors together, but tight pin butts may be used if it is essential to fold the doors into the minimum space. As may be seen from the table, Fig. 13, the use of tight pin butts enables the hinge pin in some cases to be set very close to the edge of the doors because it is not necessary to make allowance for the removal of the hinge pin. No particular advantage is claimed for the loose pin butt except that it is somewhat easier to remove the doors. Butts

ferent thickness doors, surface hinges are impractical unless they are offset. The dimension *B* for calculating the width of the door will then be one-half the thickness of the door plus half the space between the doors when folded with the particular style of hinge used.

The hangers for accordion doors are of two general types, viz., two-wheel and four-wheel. The two-wheel hangers are designed for use on each full size door, but the four-wheel hangers are attached to each alternate door, beginning with the door farthest from the half door. Generally speaking, the four-wheel hangers are preferable. The plans in Fig. 12 show the correct number and location of four-wheel hangers for different numbers of doors. Half doors require no hangers. To attach the hangers properly, the doors should first be hinged together, following the suggestions previously given.

and then folded. Scribe a line across the center (considering width) of all the doors at the top, then draw center lines (considering thickness) on each door intersecting the first line, as in Fig. 14. To insure correct folding it is essential that the pendant bolt of all the hangers be located exactly in the center of the doors. Screw the hangers to the doors so the center of the pendant bolt will be located exactly over the point where the lines intersect.

It is sometimes desirable to have a passage or service door between the two rooms, and to accomplish this the two methods given in Figs. 15 and

method, Fig. 16, can sometimes be used to good advantage, and is perhaps the better of the two where conditions permit. This plan and elevation shows two full size and one half door folding toward one side and a separate swing door hinged to the opposite jamb. This swing door is used for service independent of the folding doors. When the partition is opened, the service door is swung back against the side wall. The passage door in both cases locks to the adjoining folding door.

When all doors fold to one side, a length of track equal to the width of the opening, less 8 in., is re-

Fig. 15—Plan and Elevation of Partition Having Four Full-Size Doors and Two Half Doors

Fig. 18—Another Method of Construction Sometimes Used

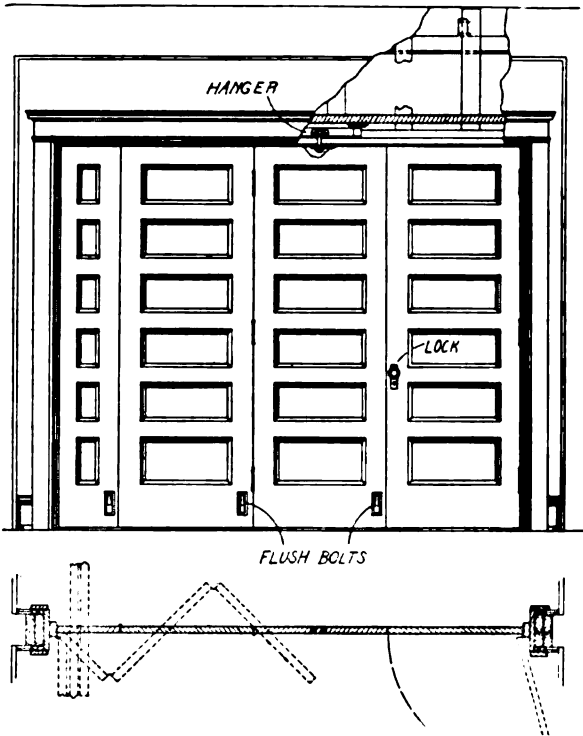

Fig. 16—Plan and Elevation Showing Two Full-Size and One Half Door Folding Toward One Side and a Separate Swing Door Hinged to Opposite Jamb

Fig. 19—Horizontal and Vertical Sections Showing Type of Floor Guides Often Used

Arrangement of Sliding Partitions—Use of Accordion Doors

16 are in use. Fig. 15 is a plan and elevation of a partition consisting of four full size doors and two half doors. The left half of the partition is hung as described above. At the right side, instead of attaching the hanger to I, the door farthest from half door, it is attached to the next door. The door I is then free to be used as an ordinary swing door. This method is the more common and gives a reasonable degree of satisfaction on narrow doors, but for wider doors it is subject to difficulty from the door dragging on the floor. It is also necessary to use a little more care when folding the doors, especially if floor guides are not in use. The second

method, Fig. 16, can sometimes be used to good advantage, and is perhaps the better of the two where conditions permit. This plan and elevation shows two full size and one half door folding toward one side and a separate swing door hinged to the opposite jamb. This swing door is used for service independent of the folding doors. When the partition is opened, the service door is swung back against the side wall. The passage door in both cases locks to the adjoining folding door.

When all doors fold to one side, a length of track equal to the width of the opening, less 8 in., is re-

be spaced from 24 in. to 30-in. centers excepting the first two or three brackets over the hall door. These should be spaced from 12 in. to 18-in. centers because of the additional load to be supported at this point when the doors are folded. Use the closer spacing of brackets for heavy doors.

A vertical cross-section, showing typical overhead construction for supporting track of a prominent make, is designated as Fig. 17. The conditions on each building, of course, determine to a large extent the particular structural arrangement. A header to which the track brackets are to be bolted is attached to the studding a suitable distance above the soffit. This dimension varies from $3\frac{1}{8}$ in. to $5\frac{1}{4}$ in., according to the size of track used. A 2 in. x 4 in., as shown, is suitable for all except the largest size of track, which requires a 2 in. x 6 in. Head in the ends of the studs with a 2 in. x 2 in. and nail $\frac{7}{8}$ in. x $1\frac{1}{2}$ -in. furring strips to the side of the studs a sufficient distance above the top of soffits to permit a screwdriver to be inserted between it and the 2 in. x 2 in., for the purpose of engaging the bolts through the side of the track brackets. The distance *J* will vary from $3\frac{1}{4}$ in. to $4\frac{3}{4}$ in. The soffits and casings should be attached with screws, as shown in the illustration, so they may be removed without damage. This will be found convenient in case it should be necessary to remove the track. Head casing not less than 6 in. wide is required for the small sizes of track, but with the largest size the width of casing should not be less than 8 in. Allow $\frac{1}{4}$ -in. clearance between top of doors and bottom of soffits.

Fig. 18 illustrates another method of construction which is sometimes used. In this the track brackets are attached directly under the ceiling or beam. The track is then inclosed with a steel casing which is attached to the brackets with small machine screws, the brackets having been previously tapped to receive the trim. The casing may be grained to match the woodwork or otherwise finished. This method is particularly adaptable when the partitions are applied to old buildings, but is also advantageous in new buildings because of the easy accessibility to all the fixtures.

A flush door bolt should be used at the bottom of each door, as shown in the elevation, Figs. 15 and 16. This gives required rigidity to the partition.

Floor guides similar to Fig. 19 are sometimes used. These serve to steady the doors in operation, but are not essential to a satisfactory installation. One should be located in the bottom of each alternate door in a line exactly under the center of the hanger pendant. When using floor guides, a type of flush bolt, which will not interfere with the guide strips, should be selected.

(To be continued)

Building Operations in Old New York

In 1877 there were 1432 buildings planned in New York City, estimated to cost \$13,365,114; in 1869 the number planned was 2342, estimated to cost \$40,352,058, and in 1909 the building construction planned involved an estimated outlay of \$186,047,477, but the city in the last-named year embraced five boroughs instead of one.

Combination Club, Hotel, Office and Salesroom Building

A rather novel addition to the hotel district of the city of New York is to be erected in West Forty-second Street, just east of Broadway, on a plot 50 x 100 ft. in size and estimated to cost in the neighborhood of \$1,000,000. It will be a combination club, hotel, office and salesroom building, twenty-five stories in height, and the tallest skyscraper in that section of the city.

In the basement and ground floor there will be a rathskeller and restaurant; on the second floor, conference and club rooms, and on eighteen of the upper floors there will be booths for trade exhibition purposes, also offices and reception rooms. The plans have been prepared by architects Helmle & Corbett, and the structure will be known as The Merchandise Hotel. It will be intended as headquarters building for American manufacturers and is being put up by the Bush Terminal Company. Branches of the new institution are to be established later at London, Petrograd and Moscow.

Supplement of Colonial Door Treatment and Modern Lighting Fixtures

We take pleasure in calling the attention of our readers to the added feature in this issue of the paper in the shape of a four-page supplement of heavily-coated paper, carrying finely executed half-tone illustrations of special value to the young architect and the progressive builder, who are constantly being called upon for suggestions with regard to various features in connection with house design and equipment. Of the four pages in question, three are taken up with window and door treatment of the Colonial order, and represent examples of modern construction to be found in the vicinity of New York. The fourth page deals with lighting fixtures and bowls of Parian ware and of a character to command the attention of the artistic and discerning architect, builder and house owner.

Instrument for Testing Floors and Walls of Buildings

A device intended to be used in testing floors, walls and columns of buildings in order to determine their safety and carrying strength has just been designed by Assistant Superintendent of Buildings D. E. Hooker of Seattle, Wash. It is known as an "Extensometer," and is of such sensitiveness that it measures the movements of buildings to the ten-thousandth part of an inch. In explaining the use and purpose of the instrument Mr. Hooker points out that when a floor or column in a building is loaded a slight movement takes place requiring a most delicate instrument to detect the change. When a floor slab is loaded the under surface stretches and becomes longer while the upper surface compresses and becomes shorter. By measuring the amount of the change and taking into consideration the kind and quality of the material and the amount of the load, it is possible to figure out the safe carrying capacity of the building. In reinforced concrete structures particularly this is important because in them weaknesses of construction are not otherwise readily discernible.

Some Practical Suggestions for the Architect and Builder in Door and Window Treatment

A Portable Collapsible Workbench

A Form of Bench Described by an English
Writer Possessing Many Features of Convenience

IN view of the comments which have recently been appearing in these columns regarding carpenters' workbenches and their method of construction, the accompanying illustrations of what may be termed a collapsible bench contributed by a correspondent to one of our London contemporaries, may contain suggestions for American mechanics. The bench is of a character to meet many requirements where a portable affair is used only occa-

According to the London *Building World* correspondent, the top should be at least $1\frac{1}{2}$ in. thick, formed of two boards jointed together. In order to keep it true it should be clamped and tenoned, as shown in the enlarged detail, Fig. 6. The top should be hinged to the rail A, and the side of the bench hinged to the top, as shown at B in Figs. 3 and 4. For this purpose 3-in. butt hinges are used.

The wall piece, C, shown in the various sketches,

Various Details of a Collapsible Workbench for Building Mechanics

sionally. When the bench is not in use it may be dismantled, so to speak, and made to occupy small space against the wall. A general view of the bench is shown in Fig. 1, a front elevation in Fig. 2, a side elevation in Fig. 3, and the end appearance of the bench when folded against the wall and not in use in Fig. 4. In Fig. 5 is another view of the bench when folded against the wall.

should first be firmly screwed to the rail of the top, A. The legs should be hinged at the top to this piece and also at the bottom to the strip, D, Figs. 1 and 2, each strip to be sufficiently thick to project from the wall the thickness of the wall piece, C. The latter can be attached to the skirting board with a few screws.

The wall piece, C, if against a lath and plaster

partition, can be firmly and easily fixed to two or three of the studs of the partition with a half dozen screws. On the other hand, if it is against a brick wall, a few holes should be drilled into the wall and hardwood blocks driven in, or, better still, probe the wall with a long fine bradawl until the joints are found and then with a steel chisel cut a hole about $\frac{3}{4}$ in. square and 3 or 4 in. deep. These holes may then be fitted with hardwood blocks, into which screws are inserted through the wall piece.

The leg to which the screw is attached is of a larger size than the others. The side and top of the bench when folded can be kept in position by means of a hook and eye, as shown.

A simple method of jointing the legs and rails is that of lap dovetailing, the details being shown in Figs. 7 and 8. One of the improved iron stops which requires letting in will be found a convenient form of bench stop. The bench here shown may be made additionally firm by inserting a few screws through the side into the legs and through the top into the rails. When it is desired to remove the bench all that is necessary is to withdraw these screws.

Garage on Old Landmark Site

After having remained vacant for many years a site on Broadway, just below Astor Place and running through to Lafayette Street, which in a way is notable for the variety and fate of the buildings which from time to time have occupied it, is about to be improved by a seven-story garage and service structure, estimated to involve an expenditure of something like \$700,000. The plot has a frontage on Broadway of about 121 ft. and on Lafayette Street it will have a frontage of 135.9 ft. According to the plans which have been prepared by William Steele & Sons of Philadelphia, Pa., the building will be of reinforced concrete construction with ample illumination on both streets. Each of the seven floors will contain 30,000 sq. ft. of floor area and every floor will be divided with fire walls built across the center of the structure.

An interesting feature will be the use of the roof as a recreation space for employees. The first four floors on the Broadway end of the building will be used for automobile garage, storage and repairs, while the fifth, sixth and seventh floors will be given over to storage purposes.

On the Lafayette Street frontage the first floor will be used as the main shipping department, and here driveways affording easy access to the cars will be provided. Above the main floor the space will be used for storage and manufacturing.

The building will have three freight elevators, one combination passenger and freight elevator, and three elevators for automobiles. All passenger elevators will extend to the roof of the building.

In addition to the elevator system, the building will be equipped with four smoke-proof, fire-tower stairways which will extend from the first floor to the roof level. For the exclusive use of the employees of the garage one extra smoke-proof, fire-tower stairway will be installed from the first to the fourth floor.

As intimated above several landmarks occupied this site during the past half century. In the late

seventies a portion of it was occupied by a church, which was later destroyed by fire. After remaining vacant for a time the then well-known theatrical firm of Harrigan & Hart erected on the site an attractive theater, wherein these well-known personages amused the public for several years when the building was destroyed by fire. Again the site remained vacant for a time when it was improved by the erection of what was known as Ye Old London Street, which looked something like the Tower of London from the outside, and inside was intended to typify some of the old-time streets in London, with the quaint stalls and which partook more or less of an exhibition place. This not proving a success, the old Broadway Athletic Club had its headquarters there for a time, since when the site has remained vacant, the present purchaser having acquired the property some twelve years ago.

Paneling in Olden Times

In the olden days a house was not thought complete or up to date without a quantity of oak or other hardwood paneling. This paneling was usually of rather intricate design and was all mortised together to make a good, sound, well-fitting job and something that would last as long as the building itself. In this generation of "spike tenon" building, however, the demand is not for durability as much as it is for appearance and price, most generally the latter, and for that reason the panel work of today, while an artistic and pleasing effect, is often liable to open up at the joints before the first winter is gone, says George M. Peterson, in the *Pittsburgh Gazette Times*.

Although the present-day paneling probably costs about as much as did the real high-class work of other years, the cost is due, not to any better materials or any better workmanship, but rather to the high cost of poorer materials and ordinary labor.

Also there are very few of the present-day carpenters who can turn out a really first-class paneling job, due to the fact that perhaps 90 per cent of the paneling used is turned out in a mill and merely assembled on the job.

Of course, there are a number of cabinet makers who can do as good, or perhaps better, work than the old-timers, but by the time they get the wages that are demanded today and work at the same speed as their brothers did thirty or forty years ago for less than half the wages, the cost of paneling is brought to such a high price that it is almost out of the question for the medium-priced home.

Public opinion also has changed in regard to panel work, so that it is very seldom that one sees any panel work in the modern dwelling, except in the living rooms, dining rooms, reception halls and perhaps on a stairway, and only the dining room wainscot is paneled in the great majority of houses.

At the annual meeting of the National Fire-Protection Association held in Chicago on May 9, one of the important topics for discussion was that of safeguarding school children from fire. The topic is subdivided into Planning School Buildings for Safety, Exit Drills and Fire Escapes and Care of School Buildings.

A Church Edifice of Unusual Design

The Building Is So Arranged That at Some Future Time It May Be Used as a Church Club-house

BY CHARLES ALMA BYERS

THE church edifice here shown, although most attractive from every point of view, is of truly unique design, both inside and out. Outwardly it might be readily mistaken for a clubhouse, and on the inside is found not only the customary pulpit but also a roomy stage, equipped with drop curtain and footlights. Although expected to serve as a real church structure for several years to come, it is designed to some day become a church club-house, when a more pretentious church building can be erected on the ground adjoining, in front. Hence, its uniqueness is not without reason.

The outside dimensions of the building are 79 by

partially individual roofs, of the comparatively flat and circular type, which break forth from the slopes of the main roof. The building possesses no spire or steeple, and has a general appearance of being low and rambling. The outside finishing timbers are unsurfaced, to match the split shakes, and, aided by the contrast of colors, a rather rustic effect is made to dominate the whole exterior.

There are two entrances—one on the front and one on the side facing the side street. The former is by way of a porch which is floored with concrete and is principally uncovered save by pergola beams, and which is reached by a short flight of concrete steps at one end. The other entrance is also pro-

Photographic View of the Wilshire Christian Church at Los Angeles—Architect W. C. Harris of That City

99 ft. Its foundation, of which considerable is exposed, is of solid concrete, but the chimneys, as well as the walls of the window bay on the front, are of cement-stucco-over-brick construction. The framing timbers are of Oregon fir, and the outside walls are covered with split cedar shakes, stained a dark brown. The roof is shingled, and is painted a very light green.

The structure occupies a large corner lot, and the three corners exposed to the front and side streets are designed, with circular walls, as sort of low tower extensions. These are covered with

board flooring and steps and is covered with a shingled roof, as well as being inclosed at the ends.

The interior arrangement—that is, of the main floor—will be seen from an inspection of the plan. The auditorium, 59 by 64 ft. in size, has, together with the balcony, a seating capacity of 600. The pulpit is located at the end opposite the front entrance, and adjoining it on the right are the baptistry and the choir loft. The stage, previously mentioned, is 17 ft. 6 in. by 31 ft. in size, and is located so as to face the side entrance. It, like

the choir space, is elevated 33 in. above the main floor. The footlights, with which this stage is equipped, are arranged in the usual fashion, but a strip of flooring has been prepared for use as a lid-like covering for the light gutter, when the stage, as such, is not required. Both rod and drop curtains are provided, and by these the space may be entirely concealed, or the stage can be utilized as a Sunday School class-room.

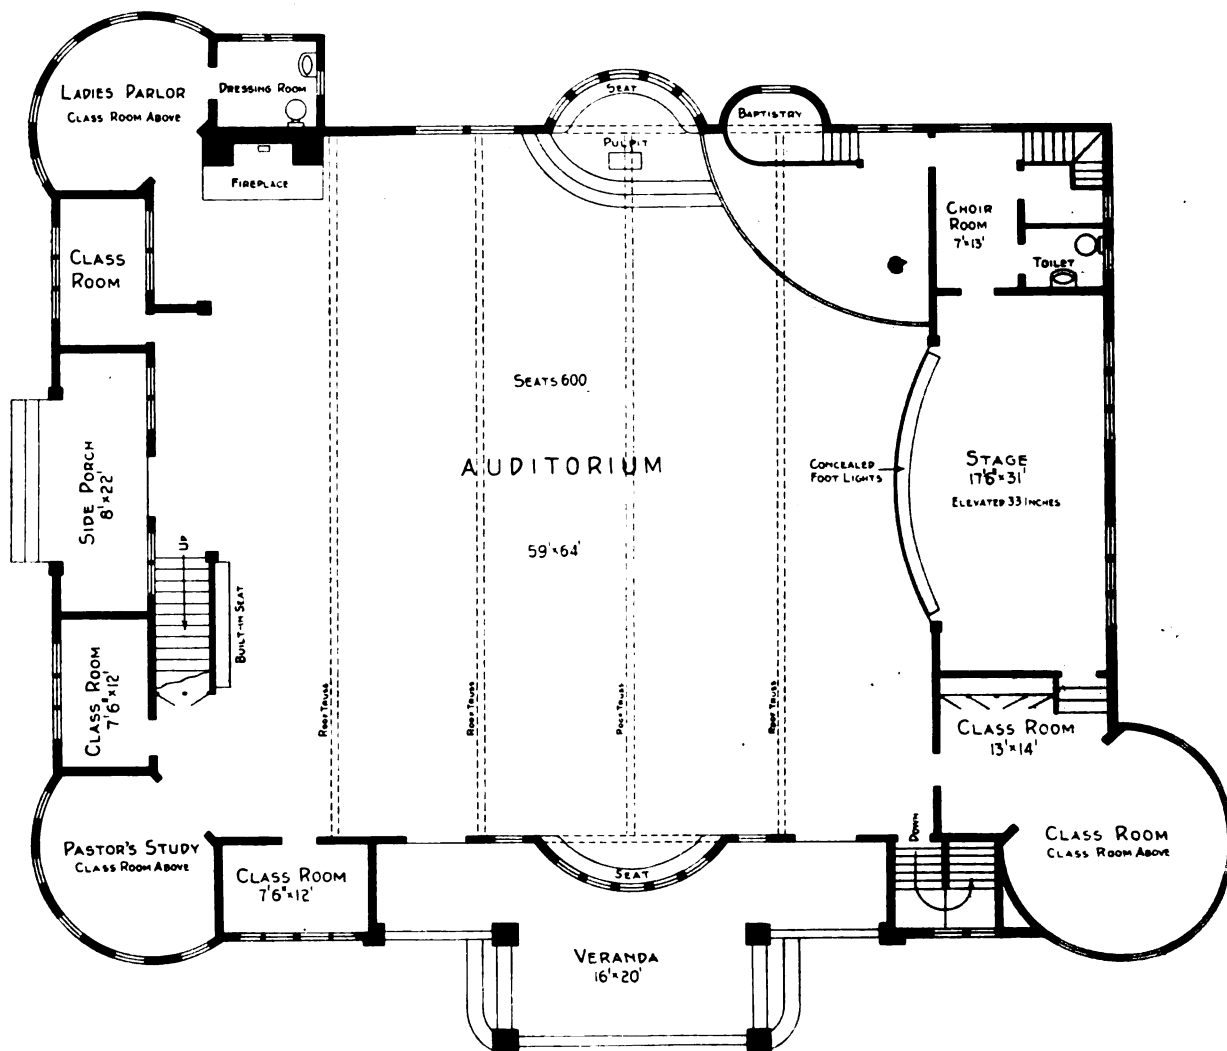

The seats of the auditorium are movable, and hence may be placed to face either the pulpit or the stage. The balcony seats face the latter, and yet they command a very satisfactory view of the pulpit. The floors throughout are of pine.

The circular corner extensions are two stories in

the plastered walls are tinted a light buff shade. The windows which admit light to the auditorium are of art glass, but those of the class and other small rooms are of ordinary glass. A built-in seat occupies the curve of the bay on the front, and a similar seat, with a hinged top, is located along the stairway leading to the balcony.

Although including a well-equipped stage and otherwise designed to be eventually converted into a church club-house, with but few changes, the interior of the structure has a true churchy appearance, and as a church edifice is well arranged.

Underneath the structure is a basement which covers the entire building space. It is walled and floored with concrete, and is utilized principally as

Floor Plan of Church Edifice of Unusual Design—Scale 1/16 In. to the Foot

height, exclusive of the basement, and in and adjoining them, on the two floors, are the several Sunday School class-rooms, the pastor's study, a ladies' parlor and dressing room, and so forth. A small choir room, a second lavatory and one of the two stairways leading to the basement occupy the other corner, which is one story in height.

In one end of the space beneath the balcony is located a massive pressed-brick fireplace, with a hammered-brass hood. Before it is frequently held the prayer-meeting service. The auditorium is unceiled, an interesting arrangement of beams and trusses being exposed overhead. The interior wood-work is of Oregon fir, stained a light brown, and

a large banquet room, with a fair-sized kitchen, fully equipped, in one end. The portion devoted to the banquet room, however, may be divided into smaller rooms by the use of movable partitions, designed after the style of large folding screens, which are provided.

Both the main floor and the basement of this unique building are heated from a furnace, which is located in a concrete-lined pit.

Known as the Wilshire Christian Church, the building is located in Los Angeles, Cal., and was designed and built by Will C. Harris, architect, of that city. The cost, including seats, furnace, etc., was approximately \$18,000.

Suburban Cottage of Moderate Cost

Design Forms Basis of Colored Supplemental Plate—
Details of Construction of Interest to the Builder

WE have taken as the basis of our supplemental plate this month a story and a half frame cottage of a design well suited for execution in any section of the country. It is of moderate cost construction and noticeable features are the veranda extending entirely across the front of the building and the dormer windows which break up the long sweep of the roof. The main body of the house is covered with $\frac{3}{4}$ x 4-in. and $\frac{3}{4}$ x 8-in. resawed siding laid in alternating courses over 2-ply building paper. The second story walls and gable ends are covered with 1 x 6-in. shiplap laid horizontally, over which are nailed 1 x 2-in. furring strips placed 8 inches apart. These are covered with

the left is the dining-room with a built-in buffet and china closets, while at the right is the kitchen communicating with the dining-room through a well-equipped pantry and also with the living room through a passage from which rise the stairs to the second floor. In the pantry the sink is placed directly under a window, thus giving ample light. Immediately at the left of the sink is a cooling closet with removable wire screen shelves and having screen vent at top and bottom to run to the outside of the building. The stairs to the cellar lead directly from the pantry, being convenient to the kitchen.

On the second floor are three sleeping rooms and bathroom, together with ample closets for clothing.

A Suburban Cottage of Moderate Cost—Front Elevation—Scale $\frac{1}{8}$ In. to the Foot

6-in. shakes placed 1 in. apart and exposed 8 inches to the weather.

The rafters are covered with 1 x 6-in. sheathing boards, over which is a layer of two-ply building paper, and on this in turn are laid Star A shingles exposed $4\frac{1}{2}$ inches to the weather. The same kind of paper is placed over the sheathing boards on the outside walls.

Reference to the accompanying floor plans shows the living room to extend entirely across the front half of the cottage and having at the extreme left an open fireplace served by the outside chimney shown on the supplemental plate. The hearth is supported by a trimmer arch of concrete 20 in. wide, extending the full length of the chimney breast. The fireplace is to be lined with firebrick laid up in fire clay and the face is to be laid up with pressed brick in colored mortar. Beyond the living room at

It will be noted that the stairs are well lighted by a double window at the broad landing clearly shown on the plan.

According to the specifications, all foundation walls, footings and piers are to be of concrete mixed in the proportion of one part Portland cement, three parts sand and four parts broken stone of such size as to readily pass through a 2-in. ring. A 3-in. tile drain is to be laid around the foundation wall and connected with the sewer.

The walls of the chimneys are to be 4 in. thick, and the flues are to be $7\frac{1}{2}$ x $7\frac{1}{2}$ in. in the clear for one outlet and $7\frac{1}{2}$ x $11\frac{1}{2}$ in. in the clear for two outlets; all flues to be plastered inside and laid in cement mortar from the top to the ceiling joists below. The outside chimney for the living room is secured to the framework of the building with iron anchors placed every 3 ft. The exposed portions of

the chimney are to be constructed of ruffled brick.

The porch columns are to be staved up 2 in. thick and made of poplar or white pine planks, according to preference of the owner. The ceiling of the porch is to be covered with 1 x 6-in. tongued and grooved V pine ceiling. The front porch floor is to be made by filling in the area with earth thoroughly soaked with water and tamped, and on this a concrete grouting 3½ in. thick is to be placed. The grouting

6 ft. 8 in. high with hardwall plaster, and all corners are to be protected with metal corner beads.

The framing timbers include mud sills 2 x 6 in., first floor joists 2 x 8 in., second floor joists 2 x 10 in. and ceiling joists 2 x 4 in., all placed 16 in. on centers. The studs are to be 2 x 4 in., also placed 16 in. on centers, and the rafters are to be 2 x 4 in., placed 32 in. on centers. The floor joists running lengthwise under partitions are to be double. All

A Suburban Cottage of Moderate Cost—Plans and Elevation

is to be covered with a finish coat of cement ½ in. thick mixed in the proportion of one part Portland cement to one and a half parts coarse, sharp sand, and to be marked off to represent tile.

The cellar of the house is to have a concrete grouting floor of the same general construction, the floor to be graded to a bell trap. The plastering of the rooms is to be two-coat work with sand finish. The kitchen and bathroom are to be wainscoted

stud walls and partitions are to be bridged with 2-in. material. All corners are to have diagonal braces, and all openings of 5 ft. or over are to be thoroughly trussed.

The floors are to be double, the sub-floor consisting of 1 x 6-in. pine, over which is to be placed a layer of two-ply building paper, and on this the finish floors are to be laid. In the living and dining rooms the finish floors are to be ⅞-in. tongued and

grooved quarter-sawed oak, blind-nailed every 8 in. They are to receive two coats of wax well rubbed between coats. The floors in the other rooms are to be 1 x 4-in. tongued and grooved pine.

All woodwork in the living and dining rooms is to receive one coat of stain, one coat of filler and two coats of Berry Bros. flat varnish. The woodwork in the bedrooms, bathroom, back hall and kitchen is to receive three coats of flat white and one coat of white enamel.

All sand-finish plastered surfaces are to be sized and receive one coat of tint color.

The doors, except the front entrance door, are to

inch shelves and 1½-in. door glazed with bevel-plate mirror.

The sink in the pantry is to be 18x30 in., of white enamel and with nickel-plated fittings. The laundry is to have a two-part porcelain enamel tray with hot and cold water connections. A gas water heater and boiler set on a bracket, and to have a pilot light, is to be provided.

The house is to be piped for gas and wired for electricity, the wire system to conform to the rules and regulations of the National Board of Fire Underwriters.

The exterior siding of the house is to receive two

A Suburban Cottage of Moderate Cost—Miscellaneous Constructive Details

be 1⅜ in. thick and of the five-panel Colonial type. The front door is to be 1¾ in. thick, of veneered oak on the outside and slash grain pine on the inside. It is to be glazed with double plate glass.

All sash is to be 1⅜ in. thick, and double-hung windows are to be fitted with Sampson or Silver Lake sash cord and balanced with iron weights. All casement windows are to be hung on Parliament hinges.

The plumbing fixtures are to be of the modern type. The bathroom is to be equipped with one 5-ft. porcelain enamel tub with 3-in. roll rim, a porcelain enamel lavatory, a closet with low-down china tank, wash-down bowl and nickel-plated piping. There is also to be a medicine cabinet fitted with half-

coats of silver-gray mixed paint and the shingles of the roof are to be stained green in color.

Blueprints covering plans, elevations and various details of construction all to convenient scale for the builder, together with typewritten specifications, can be obtained by any interested reader for \$10. In ordering designate design No. 660.

According to the Bulletin of the Industrial Commission of the New York State Department of Labor the percentage of unemployed was smaller in March this year than was the case in the corresponding month a year ago and compares favorably with each of the four years preceding except 1913.

Cabinet Work for the Carpenter

Details of Construction Relating to What Is Known as a "High-Boy" and a "Low-Boy"

By PAUL D. OTTER

THE full meaning of the description contained in the dictionary definition as below is no doubt mixed up with a certain amount of social and political significance during the seventeenth and eighteenth centuries, evidently with some humor in designating the family linen stand as a "high-boy" or a "low-boy," with somewhat the same distinction as existed between the high churchman of the Tory and the low churchman of the Whig party.

As we delve into the history of family furniture

Fig. 1 represents the general proportions of the "high-boy" in a simplified form, a composite in which the Jacobean is more evident in the knurled turnings of the lower structure, or stand. This pattern of turning Fig. 5, can be produced on any lathe. Should the enthusiast aspire to a more typical rendering of the Jacobean turning, he can leave the knurled portion turned blank and proceed to carve with grooving chisel and flat oval, the spiral, or single twist, finishing up with wood rasp and sandpaper. The method of marking out the spiral

Fig. 1—Front Elevation Fig. 2—End Elevation
Scale 1/16 In. to the Foot

Cabinet Work for the Carpenter—Details of a "High-Boy"

Figs. 3 and 4—Details of Top Cornice and Base Mold of "High-Boy"
—Scale 3/4 Full Size

Fig. 5—Strainer Rail of "High-Boy"—Scale 3/4 Full Size

we find that the "low-boy" sprang from the lowly box with hinges and a padlock, then to the hutch, chest, or coffer with some pretensions to form and ornament; later to its elevation on low leg-like supports, and finally to its graceful development during the middle of the XVIII century, and its natural enlargement to the "high-boy" proportions of the well-ordered mansion.

"High-boy—A tall chest of drawers supported on legs from 18 in. to 2 ft. high. Those on shorter legs are called low-boys."—*Century Dictionary*.

for cutting is by tacking a piece of twine, or tape, at the beginning of the turned blank and twisting it in a natural spiral to the other end and tracing its course with a pencil.

So much for the Jacobean. To give a rendering of "William and Mary" style, a stand or base may be substituted with that form of leg, shown in Fig. 8, the detail of which is fully indicated. The upper carcase containing the drawers and consisting of top and base of which Figs. 3 and 4 are details, would be quite proper for either a simple

Jacobean or "William and Mary" treatment. The top and base consist of a solid $\frac{7}{8}$ x 1 in. panel molded as shown, with the stuck molding mitered around as an after finish.

With the aid of the half plan of construction frame shown in Fig. 7 the building of the cabinet will be found quite easy. There are seven of these frames, the fronts of which, exposed as they are between drawers, should, of course, be of the same wood as the drawer fronts and outer sides. The sides and back part of the frames can be of any ordinary wood. Five of these frames separate the drawers; the first and seventh frames are at the top and bottom of the carcass proper, and all are secured to the solid side panel in the manner shown in Figs. 6 and 7.

The inner front edge of the side panels is reinforced in thickness by a carefully glued strip $\frac{1}{4}$ x $2\frac{1}{4}$ in., faced off flush on the front edge. A cleat strip $\frac{1}{4}$ x 1 in. is then glued across the inside width of the panel, upon which rests each frame in its proper spacing.

When the seven frames Fig. 7, are finished to a careful fit, allowing for cut-out ends on front rail,

Fig. 6—Showing Cleat "A" in Over Construction Frame

Cabinet Work for the Carpenter—Details of a "High-Boy" and a "Low-Boy"

as shown, the case will be ready to set up. Here some assistance may be found necessary to get the work along quickly with so many frames set in fresh glue, although the top and bottom frames could be glued up and held in bar clamps without much trouble, care being observed to have the structure squared before going ahead. Each frame could then be slid separately in its glue, along the cleat from the back side. Cabinet nails should be driven in a slanting manner through the cleat and partly into the sides.

A similar filling, in cleat A, Fig. 6, is then set in glue on top of the frames. This cleat should be of some hard wood as maple, for it does service as a guide and slide for the drawers to run smoothly, and should finally be rubbed with paraffin. The back filling consists of a $13/16$ x $2\frac{1}{2}$ in. frame with one or two middle bars and filled in with 3-ply veneer panels or $3/16$ in. compo-board. These should be set in grooves before glueing up the frame. There is a great advantage in having the frame fitted in a fairly tight manner.

The stand D, clearly shown, consists of four $2\frac{1}{2}$

in. rails set in posts on the front line of turned rails, which occupy the middle position on the $1\frac{1}{4}$ in. posts. The outcurve of the front posts is secured by glueing on front and side faces an extra thickness of 1 in. Added strength to the stand, as well as to the case, should be given by placing glue blocks and three-cornered soft wood glue strips wherever they do not interfere. Through the large corner blocks of the stand heavy screws may be set into the bottom of the upper case.

Definite size for the drawers is a matter of fact now, and their construction is in order, allowing fair play top and bottom in the final fitting. This

Fig. 7—One-Half of Case and Construction Frame

Fig. 8—Elevation of a "William and Mary" Base

Fig. 9—Elevation of a "Queen Anne" Base

is best secured by having drawer fronts, which are $\frac{7}{8}$ in. thick, made to fit snugly, but with the side panels dovetailed in a setback, or rabbett, $1/16$ in., as this allows for weather conditions. The back corners are also dovetailed without any end projection. The sides and back are $7/16$ in. poplar, or white wood. The bottoms can be of 3-ply veneers inserted in grooves $\frac{3}{8}$ in. from the bottom edge when setting up. The drawer knobs for the two smaller top drawers are $1\frac{1}{4}$ in. diameter, plain turned and set out $\frac{3}{4}$ in. The knobs for the lower drawers are $1\frac{1}{2}$ in. and are set out $\frac{7}{8}$ in.

Glued stop blocks should be set in on frames in back so that all drawers stop slightly back of the case frame and the drawer divisions.

The low-boy is a matter of diminishing height of the upper structure by leaving out the two lower drawers, or substituting one 9 in. drawer for the $7\frac{1}{2}$ in. drawer. To make a typical low-boy suggestive of "Queen Anne" style, the low base Fig. 9 is shown with the few measurements given to assist in shaping the front legs, the back legs being 2 in. square, tapering to $1\frac{1}{2}$ in. at bottom.

Construction of Old English Roofs

Massive Nature of Old Roofs—Various Styles—Moldings—Open Timber Ceilings

THE extracts which follow are taken from a lecture by Arthur Keen, a Fellow of the Royal Institute of British Architects, delivered at Carpenters' Hall, London, under the auspices of the Worshipful Company of Carpenters.

The roof has been the governing factor in the arrangement and contrivance of our buildings, and just as in the East the buildings are contrived to support and buttress the dome and its surrounding vaults, so in the North it is the roof that limits our architecture, and disposes our churches in long narrow naves and aisles and transepts that can be covered by a construction formed by timber, which is only found in limited lengths. In fact, it is the most important consideration in a plan. The old farms and cottages, the great manor houses that are among the most precious possessions of this land owe half their beauty to their simple straightforward roofing. The long main lines and dignified gables, and the great chimneys upstanding at regular intervals group themselves into beautiful arrangements, and offer a sky line that is unrivaled in any other kind of buildings.

The Roof as Carpentry

Now the simplest possible form of roof is the lean-to, just a sloping beam laid from a high wall to a low one, and it might almost be dismissed from consideration, only it is a roof that is universally used, and often receives very skillful design and workmanship.

Used in churches, it enables the interior to be really well lighted by means of clerestory windows. What is done in most churches to secure good light is to raise walls on the arches, between the nave and aisles, with windows in them, and to roof the aisles with lean-to roofs at a lower level. These lean-to roofs are generally very flat, so that the wall containing the windows may not be too high. A wall on arches is not a very staple thing, and the lower it is the better for its strength and security, and, of course, the cheaper. At the same time, if the aisle roof is a flat one the side walls can be of a good height, and thereby the dignity of the church is much enhanced, and the aisle windows made larger than they would be in a low wall. Sometimes these roofs are of lean-to form, and sometimes they are flat roofs sloping both ways.

Massive Construction of Old Roofs

Most of the old roofs are of very massive construction; often there may be quite twice as much material in them as a scientific carpenter might think necessary. So obviously is this the case that in most instances the old carpenters laid their rafters flat instead of on edge after the modern fashion. They realized that in the course of the cen-

turies of a building's life all kinds of things may happen. Alterations may have to be made, water may get in and rot off half the substance of a beam, a fire may occur, thatch may be replaced by tiles or lead. If there is plenty of material, the decayed wood can be cut out, and a perfectly sound repair can easily be made, and in any case a building with a large reserve of strength will suffer neglect for a long period without collapsing. In old work it is with the roofs as it is with the walls, which are so thick that they will remain standing long after reaching the point at which a thin modern wall built of better material would fall.

One of the best looking roofs I ever saw was at North Walsham in Norfolk, and there was not a molding on it, but the timbers in it were enormous. It is a very interesting example, because it is so contrived that arcades, which run from end to end of the church without any cross walls are buttressed, and stayed securely by the nave and aisle roofs being connected. The tie beams run right through the stonework of the arcading, and are framed to upright wall posts on both sides, so that the walls are held as in a vise, and they have as a matter of fact remained quite upright for nearly 600 years.

Moldings on Old Roofs

Incidentally, I may point out that the molded work of the old roofs is always wrought out of the solid wood. Carved and pierced crestings are cut in separate pieces and fixed on, always in an honest an obvious way, but the moldings are worked on the solid. They are ornamented construction, not constructed ornament.

The old carpenters loved the sweet simplicity of stiff cross beams of enormous size upholding the roof, and preventing any outward pressure. Lead being a favorite covering material, it follows that many roofs are practically flat, and framed like a timber floor with big cross beams, smaller longitudinal ones called purlins, and still smaller filling timbers called rafters. They have, of course, a slight slope to the two sides; they are richly molded, paneled, ribbed and carved, and often have elaborately-carved brackets to support the main beams.

Constructional Problems

The constructional problems connected with roofs are mainly two in number—to prevent outward thrust, and to prevent the rafters from bending; and it is in dealing with these two problems that most of the scope for decorative treatment is found. Some of these nearly flat roofs have the cross beams cut out of bent trees, so as to follow the slope of the roof, but it is more usual to cut the beam deeper in the center than at the ends.

In most old roofs there was a good deal of reliance placed on the resistance offered by the thick heavy walls, but at the same time every effort was made to reduce the outward pressure on them caused by the sloping roof timbers.

A Trussed Rafter Roof

The old builders put a short timber across the wall which was 2 ft. or more thick, framed the foot of the rafter to the outer end of it, and then from the inner end of it they put a short upright piece also framed to the rafter. At the same time they put cross pieces higher up from rafter to rafter, and other pieces across the angles, all pegged together, and this gave them what we call a trussed rafter roof—that is to say, a roof in which each pair of rafters is trussed or framed together so as to be self-supporting. It is a type of roof that was used continually in the Mid-Gothic period—in the fourteenth century and onward, and with endless variation in the arrangement and proportions of its parts. Generally the pitch of the roof is a steep one, so as to reduce as much as possible the thrust on the walls. In the West country the inner struts and cross pieces were often curved and made continuous, so as to give the roof the appearance of a vault. In many cases, and again especially in the West, the underside of these roofs, whether arched or angular, was boarded to form a ceiling divided into panels by molded ribs with carved bosses at the corners. This was done especially at the east end of the church, and very often the panels received most beautiful color decoration in emblems, monograms, and leaf or diaper work.

What we may call an open timber ceiling in a mediæval building, and an example that is interesting to Londoners, is that at Crosby Hall, pulled down in 1908 and re-erected at Chelsea. There were great crossed scissor beams to tie in the roof, and this ceiling was a practically independent construction below them. One imagines the ornamental pendants as being the lower ends of constructional posts, which, however, is not the case.

(To be continued)

Model Showing Portland Cement Manufacture

A model which is a miniature of a real cement plant and covers 80 sq. ft. has just been completed in connection with the educational exhibition work of the Division of Mineral Technology of the National Museum at Washington, D. C. The design and layout of the plant are such as to enable the visitor to follow successively the various steps of the process of cement manufacture by walking around the model. Those who have viewed it state that a person can learn more in a half hour by viewing it than spending a whole day in an actual plant.

Portland cement may be defined as a product made by burning limestone and clay, which has been mixed so as to form a certain composition, and grinding the resulting "clinker" to powder. In the early days much mystery surrounded the manufacture of Portland cement when it was first discovered by a bricklayer of Leeds, England. He found by mixing water with a compound of Thames chalk and Medway mud he could compound an artificial water cement, and determined that no one should discover

his secret. When manufacturing his raw mixture he is said to have attired himself in a long black gown and the pointed hat of the mystic and to have recited mysterious incantations during his operations.

In this country the Portland cement industry had its beginnings in the Lehigh valley in Pennsylvania, chiefly in Lehigh and Northampton Counties, where John W. Eckert, a chemist, discovered that there occurred a limestone composed of approximately the correct ingredients necessary for the manufacture of Portland cement. The model represents the process of manufacture used in this section of Pennsylvania, where the limestone that is used is termed cement rock.

At one corner of the model a cement rock quarry with drills at work and steam shovels loading cars are shown. Extending along the side adjoining the quarry are the raw rock rusher building, the rock storage house, and the drier building, each with a portion of the wall cut away so that the machinery within may be seen. A single unit employed in the process is shown to avoid confusion, and enable the observer to glean an idea of the process itself rather than an appreciation of the size of the plant or the immensity of its output. For example, in the raw rock crusher building a single gyratory crusher is located under the rock bin; an elevator which carries the crushed product to the top of the building, and a belt conveyor which delivers the product to the crushed rock storage house next door. From the bottom of the building in which the rock is stored another conveyor carries some of the material to the next building, where it is dried.

Around the corner is the raw mill where the dried rock is pulverized, then come the kilns, where the pulverized rock is burned, the product being known as the "clinker." Next in order are the coolers and the clinker storage house. Turning the corner the gypsum storage house is to be seen, where is kept the crushed gypsum which is added to the clinker to retard the setting time of the finished cement. Following this building is the finish grinding mill, where the clinker and gypsum are pulverized, forming Portland cement, and then one comes to the stockhouse, and finally the packing house.

Corrugated Iron for Roofing in South Africa

The great majority of the houses of Natal, whether public buildings, stores, dwellings, warehouses or stables, are roofed with corrugated iron, and the same material also enters to a large extent into construction generally. The principal cause of its popularity, says Consul W. W. Masterson, writing from Durban, South Africa, is probably the weather, as the place is in the semi-tropics.

Tiles are used in fair quantities for the more pretentious houses and other roofing material is occasionally utilized and sometimes patent American roofing of different kinds.

Metal ceilings are as rarely used as metal shingles. Plaster with plaster-of-Paris ornaments are principally used for the more ornamental ceilings. There are also quantities of what might be called *papier mache* ceilings in use, this material coming in squares of 1½ to 2 ft. and in appearance closely resembling a metal ceiling.

Details of Decorating Wall Board

Presenting a Chart Giving Several Decorative Schemes for Every Room, with Suggestions for Floor Coverings

By JOSEPH A. PCESL

IF you glance through the newly finished and undecorated rooms of the ordinary flat dwelling you will observe blank expanses of white walls with only doors and windows to relieve the monotony. In such a building however which has its walls covered with wall board you will find in the kitchen, a wall board tiled wainscot, a plate rail in the dining room, nicely paneled walls and ceiling in the living room and so on throughout the house. Every room will be found treated individually, distinctively; yet all will be in harmony with one another. You will see, too, the wainscot cap, chair rail, plate rail, picture molding and other moldings component parts of the walls themselves; not mere fastenings.

The first presents the more difficult problem—that

and draperies. In the use of the chart, it must be borne in mind that the size of a room is apparently affected by various colors. Also, rooms facing the South should have a different treatment from those having a Northern exposure.

One advantage of the present day wall board over plaster is that it can be decorated satisfactorily with but two coats of paint without sizing. It is unsafe to apply paint over freshly plastered walls as the free lime therein will act upon the oil and produce a soap. In time the air neutralizes the lime when sizing and painting can be done without danger. Experts advise three years would not be too long to let plaster dry out; at least one year should elapse. On the other hand, the decoration of wall board can

No. 3

Details of Decorating Wall Board—The Numbers of the Panels Correspond with Those in the Column of the Accompanying Chart Headed "Design Number"

of treating the blank walls in such a manner as to make them pleasing, and to employ decorative schemes suitable for each type of room—to make the living room look like a living room and the dining room look like a dining room.

All this is solved by proper paneling in the case of the wall board house. The decorator must, however, include in the schemes he prepares more different colors for the various wall divisions which have to be in harmony, the type of stencils suitable and their color.

Here is a chart that will help in this direction. It gives several decorative schemes for every room in the house, including suggestions for floor coverings

be performed just as soon as the Board is on. This means the occupancy of a completely finished house much sooner than if it were plastered.

Some wall boards have a finished surface, grained or otherwise, which produces fairly attractive rooms without further decoration. These however, may be painted or wallpapered to suit if the natural finish is undesirable.

Do not misinterpret what is meant by wallpapered. In order to decorate a room to be finished with wall board with wallpaper, an appropriate panel arrangement should first be planned out for it, just as for painting. The wallpaper should be put on and wooden decorative strips put over every panel

joint. Of course, more than ordinary care is necessary in doing this so that the pattern of the wall-paper is correctly centered in the panels. This is the only method for using wallpaper on wall board which has proven anywhere near satisfactory. Never attempt to do so without decorative strips over the joints of the panels.

Speaking of wallpaper, it is not recommended at all in connection with wall board, for the reason that it is not as sanitary as paint. It has been barred on that account from numerous hospitals.

The greater portion of wall board used requires painting or some other decoration. But inasmuch as nearly all is surface sealed and sized, it is possible to obtain a good finish with only two coats of paint. That which is unsized should receive an application of varnish size to stop all suction before paint is put on. Glue size is not suitable being so readily affected by moisture which loosens it and causes the paint to drop off.

The manner in which this is done often determines the result of the job, whether good or bad. To do this best, instruct the carpenter beforehand to carefully set the brads just slightly under the surface of the board. Then fill the depressions with filler, scraping and removing the surplus that is not actually needed to level off the hole. If the plaster of paris and dextrine filler is used, it is absolutely essential that it be allowed to dry for twenty-four hours before paint is applied over it. This is so, because the surface hardens quickly while there is still much moisture in the body which must come out somehow. And if paint is on before it has come out the paint will be affected and discolored.

After the filler is dry apply the first coat of the selected color of paint. Allow twenty-four hours to elapse before putting on the next coat. In the case of darker colors, this would give an excellent finish; lighter colors will require three coats.

To be sure, this procedure is only for the simplest

Details of Decorating Wall Board—Chart Giving Several Decorative Schemes for Each Room in the House

Prepared paints in sealed packages are probably the most economical and convenient to use. It is well, though to select a brand made by a reputable manufacturer. Thereby one can be assured of satisfactory results—the name of the maker being the guarantee. Most home owners are to-day demanding washable flat oil paint for their interiors, feeling the effects obtainable with it are not alone artistic, but sanitary also. Wall board is perfectly adapted to it, and its slightly rough surface lends further beauty to the decoration. On plastered walls stippling is used when the same effect is sought.

In the decoration of wall board it is first of all necessary to stop, or fill, the brad holes in the center of the panels. Putty can be used for this purpose, although regular nail head filler, made of three parts of plaster of paris and one part dextrine mixed to the consistency of putty with water, is better.

The filling of brad holes is perhaps the most important of operations in decorating wall board. The greatest carefulness as well as skill are demanded.

class of work. Should those beautiful plain or mottled tiffany glazing effects be desired, a ground color of flat oil paint should be applied right after the filler has dried sufficiently. When this has also become dry, put on the glazing liquid into which the proper quantity and combination of artists colors has been mixed. As every good decorator knows, glazing liquid is first brushed on and then produced into that tiffany effect by means of a piece of burlap or cheesecloth crumpled loosely in the hand, daubed over the surface in a peculiar rotary motion.

There is practically no difference in the method of supplying water paints and that of oil paint. Although not so durable, this kind of paint is preferred by many owing to its cheapness, which allows of frequent changes in decoration. At one time its artistic finish was another reason for its use, but today flat oil paint is made to produce identical effects.

Nearly any form of decoration can be carried out on wall board more satisfactorily than on plaster.

The very same methods as used on plaster, except the omission of sizing, are followed. It can be easily enameled, especially with wall board tile, if this is desirable. Stippling, hand painting and graining are possible. Any wood or marble can be reproduced on its surface. The skill and ability of the decorator is the only limit.

In wall board rooms stencilling is almost a necessity. The paneling demands it. Stencils are inexpensive, and for the enhanced artistic effects obtained by their use the application cost is well compensated. Simple stencils are easily cut out of oiled paper by even the unskilled.

There is more woodwork used in wall board rooms than in plaster, due to the decorative strips at the intersections of the panels. For this reason

it is left off until the board has been completely decorated. These should be finished to match the door casings and other woodwork. Sometimes, however, the strips are painted in the same color as the board, which is a rather pleasing treatment. This can be done with stained and varnished or waxed trim. When the strips are painted in contrast to the board all woodwork should be alike in treatment.

Estimates for decorating wall board should be prepared with the understanding that no size is to be used, for very little unsized wall board is being sold now. It is always best to make sure, however, which must be figured on. There are also a large number of nail heads in the panels that must be filled and more woodwork to be finished, which should not be overlooked.

An Attractive Cottage at San Antonio

A Design and Arrangement of Rooms Carefully
Worked Out by the Owner and His Builder

FEW sections of the country are more in the public eye just at present than the extreme Southwest, and it may not be without interest to many of our readers to bring to their notice at this time an excellent example of the cosy-cottage type of architecture to be found in some of the more important cities of the border States. The selection which we have made is a frame dwelling of

occupying a large portion of the front; a "den" with its open fireplace; a commodious dining room with its recessed triple window and seat; a kitchen communicating with the dining room through a large pantry fitted with china closet; a conservatory opening immediately out of the dining room; a large bedroom with recessed window and seat corresponding to that of the dining room; a bath-

General View of the Cottage of Clyde V. Lancaster at San Antonio, Texas

well-considered exterior and involving an arrangement of rooms both convenient and compact. Noticeable features of the exterior are the treatment of the porch with its shingled buttresses, the attractive dormer window immediately over the main entrance, the roof effects with composition shingles placed 6 in. to the weather, and the clever manner of handling the exterior details in general.

Within, there are on the main floor a living room,

room, and a rear bedroom, which is reached from the passageway with which the three rooms on that side of the house communicate.

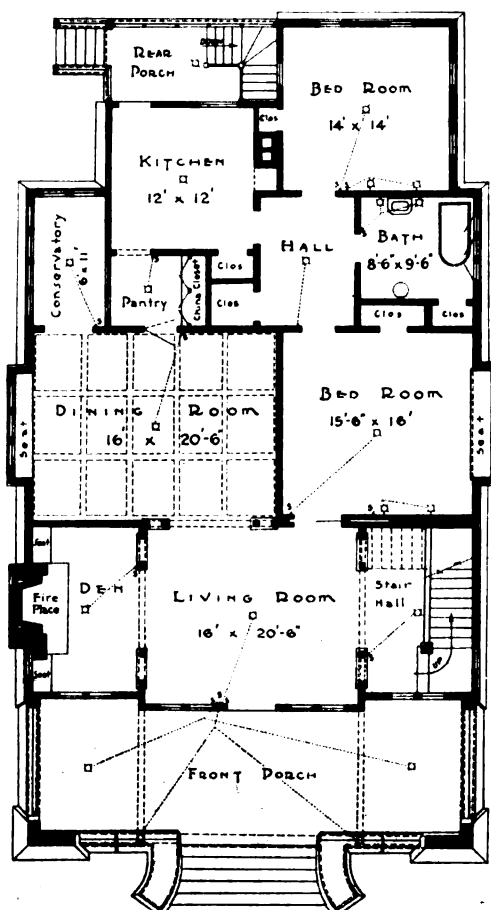

The location of the cottage is San Antonio, Tex., and owing to the peculiar formation of the soil in that particular locality the building is placed on the usual Texas foundation—cedar posts. These posts are 8 in. in diameter, are set on and imbedded in concrete piers 18 in. thick and 3 ft. sq., resting on

a clay bottom. The posts being anchored in the concrete serves to prevent to a minor degree at least shifting with the soil above the clay, which seems to be the trouble in many cases with foundations in that locality.

The sills under the outside walls are 6 x 8 in. and the cross sills are 2 x 12 in. doubled. The floor joists are 2 x 10 in. resting on the 6 x 8-in. sills and on a 2 x 4 in. strapped to the 2 x 12-in. sills, and are all securely spiked. The studs are 2 x 4 in. doubled and reinforced at the corners, with doubled 2 x 4-in. plate. Ceiling joists are 2 x 6 in., the second story not being finished.

All walls are ceiled inside with 1 x 6-in. shiplap and the same material was used for the overhead

as to grain, and with the exception of the bathroom and the conservatory is stained a dark oak and varnished. The floors are also stained dark oak, but a little lighter shade and are varnished. The bathroom and conservatory are finished in white enamel.

The doors throughout are of pine of Morgan Co.'s Craftsman "G" pattern.

Great care was used by the contractor in matching the grain of the interior trim and bringing out the beauty of the wood. Every piece was hand finished and the only mill work in the house are the doors and the windows. The stain and varnish brought out the grain of the pine with such splendid effect that the owner states it is hard to believe the entire trim is not of oak.

View in Living Room of Mr. Lancaster's Cottage at San Antonio Looking Toward the Fire Place in the "Den," while at the right is the Dining Room

ceilings. No building felt or sheathing boards were used on the outside studs as the owner deemed the shiplap siding to be sufficient covering for that climate. The siding was round edge or "No. 117," as it is familiarly known in that section of the country.

The shingles below the belt course, also in the gable ends and on the porch, are of cypress and were painted after they were put on. The shingles are exposed 4½ in. to the weather.

The 2 x 4-in. rafters of the roof were covered with 1 x 6-in. sheathing boards laid close together, and on these in turn were placed Rex-tile shingles exposed 6 in. to the weather.

The floors are of single thickness and are laid with 1 x 2-in. selected rift-sawed pine. The interior trim is all long leaf yellow pine, especially selected

The hardware is of Yale & Towne make and is of plain square brass design.

The color of all shingles except those on the roof is moss green; the walls and roof trim are ivory white, while the roof itself is clay red, all harmonizing in a most pleasing manner. The screen frames are black.

The chimney is of red pressed brick of local manufacture and the mantel is of reddish brown tapestry brick. Black mortar was used throughout with beaded joints on the exterior and raked joints on the mantel.

An examination of the plan will show the position the stairs to the second story were intended to occupy, but in building the house no stairway was erected, although if additional sleeping rooms be-

come a necessity it will be a simple matter to complete this feature. Instead of the stairway two casement sash were put in with three transom sash between, the whole scheme being worked out in a way to produce a pleasing effect from the exterior as well as from the interior.

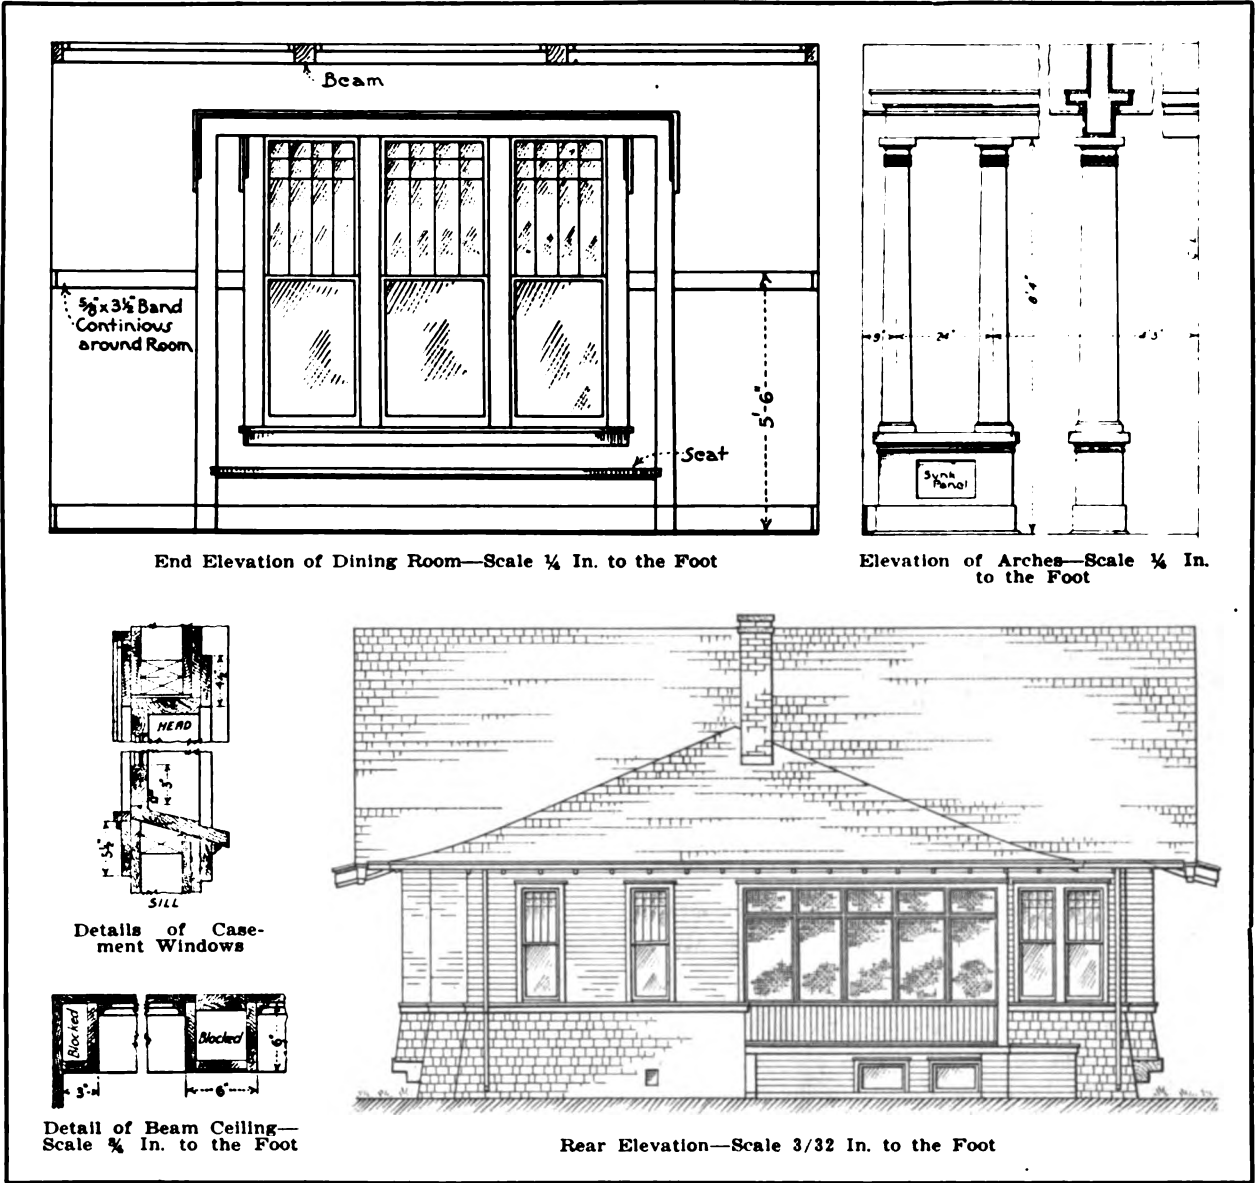

The cost of various parts of the work as furnished by the contractor was as follows:

Excavating and placing concrete piers.....	\$97.00
Cement, sand, etc.....	53.00
Brick work	210.00
Materials—lumber, shingles, etc.....	2,450.00
Carpenters' labor	1,350.00
Painting and varnishing.....	215.00
Papering	114.00
Electric wiring and fixtures.....	146.00
Total	\$4,635.00

In this connection it is interesting to state that the Rex-tile Shingles used on the house were applied by the Turner Roofing and Supply Company of San Antonio, the local agent of the Flintkote Manufacturing Company of Boston, Mass.

Federal Aid for Trade Schools

That the business interests of the country are in favor of federal aid for vocational education is indicated by a preliminary count of the votes cast in a referendum just taken by the Chamber of Commerce of the United States. Three hundred and fifty-three commercial organizations, chambers of commerce and boards of trade in forty-two States, Alaska, Hawaii, the District of Columbia, and the American Chamber of Commerce in Paris, France, participated in the ballot. According to

Elevation and Miscellaneous Constructive Details of Cottage of Mr. Lancaster at San Antonio, Texas

The cottage here illustrated is the home of Clyde V. Lancaster, who states that much of the credit for the design is due the general contractor, Charles L. Eckles, 1814 Buena Vista Street, San Antonio, Tex., who collaborated with him in carefully working out the plans.

Elliot H. Goodwin, the general secretary of the National Chamber, the four recommendations put forth by a special committee of which Frederick A. Geier of Cincinnati is chairman, were carried by the two-thirds majority necessary to commit the National Chamber.

Trade Topics—Every Reader is Invited to Participate

Why the Chimney Tops Overhang

From E. S. W., West Lynn, Mass.—In the issue of the paper for September, 1915, there appeared a question by "E. A. N." asking why certain chimney tops overhang and why their leaning is toward the east. The comments which follow were prepared some time ago and I went to considerable expense in obtaining the pictures illustrating the points discussed, but the article to clearly explain my views became so voluminous that I withheld it. In the May issue of *THE BUILDING AGE*, however, the letter of "W. B. B.," together with the inquiry of "W. W.," Baltimore, Md., concerning creosote in the old brick work having spoiled his paper hanging, have caused me to decide to send along for publication what I had previously prepared.

side, producing the curved or bent effect one can see all around him. In proof of this statement I submit the following facts.

A chimney not used for smoke but as a ventilator never bends; so also one built with flue lining rarely bends, however old.

A summer residence which has been closed from October until May for many years past has thus far required no repairs to its chimneys, but at the winter home of the owner 15 miles away the chimneys are all bent. An examination of one of these bent tops shows on one side the joint to be full, tight and level; on the opposite side the joint is large, loose and partially gone from under the bricks, while on both adjacent sides the joint varies both as regards size and tightness. It is out of

Fig. 1—A Sturdy Example of a 17th Century House

Fig. 2—House Built About the Middle of the 18th Century

Why the Chimney Tops Overhang—Some Rather Striking Examples

The conditions necessary to produce the effect described by "E. A. N." are freezing temperature and long service as a conductor of smoke. Along with this is the location of the flue in general use where more than one flue is nested in the chimney's top. This gives the direction to the lean. The initial cause of the bending is the condensation of the warm gases which arise in the flue when starting up the fire, striking the cold wall of the chimney top. This creosote is very destructive to the crystalline hardness of the mortar, destroying both its adhesive and cohesive strength. It thus permits the mortar to retain moisture and expand with the action of frost and so beginning at the top and successively working downward, as year by year the creosote destroys the value of the mortar, Jack Frost, with his mighty lever working on the cold side, tips the chimney over on the opposite warmer

level, curving upward as the top tips over. On demolishing the chimney the mortar was found discolored by the creosote—no adhesion—the mortar coming off easily and clean from the brick. It is also to be noted that the mortar crumbles easily and readily breaks apart, this being true in a lessening degree as one worked down from the top, until below the roof all changes. Here the mortar is hard, tight and requires strong blows to separate it. Upon rebuilding with this old brick the little excess of water, instead of being absorbed into the brick, flows on the surface and the work remains wet some time before jointing can be finished.

Old chimney brick are often found in new construction work and are sure to be placed on the inside face of the wall. Here they soon show dark and damp and when covered with "whitewash" show through a dirty brown spot on a white wall, and

very often have to be dug out and cast aside. This is the creosote in the brick again making trouble. So also a relaid chimney top will not stand as long as when first built. The bricks now contain a volume of this "oily creosote" and are in a condition to give it up to the mortar joints. It requires some time to get into this condition when bricks are fresh and new.

The agents, creosote and frost, are free to act on all four sides of a chimney flue, and while the creosote does affect all the joints from the inside, the warm gases on the inside and the sun's rays on the outside modify by drying the effect of the cold on the easterly and southerly sides while it is exerting its full expansive force on the other two sides. As the shape is a rectangle, this causes a bend on the side opposite from which the cold air comes.

Now I have said the location of the flue in general use governs the direction of the bend in chimneys of more than one flue, for the partitions in

have elapsed since it was overhauled or repaired.

The picture, Fig. 2, represents another fine example built about the middle of the eighteenth century. The change from the single stack to the smaller two-chimney style may be seen. These tops are 24 x 40 in. with three flues in each. The effect at the top of the flue in general use is to be noted. Here this flue is the outside one in each chimney, and the expansion of the joint, being at opposite sides of the chimney, heels the tops over toward each other.

Contrast this with the picture, Fig. 3, showing a house built about 1850. These tops have two flues, each 20 x 28 in. Here the flue in general use is the inside one or toward the center of the house. Again the expansion in the joint is opposite in each chimney, and these tops are tipped away from each other. It is plain to see in Figs. 2 and 3 which chimney, by its bend, is mostly used, and they are here shown to prove that in chimneys of more than one flue, location gives the direction to the bend.

In Fig. 4 is pictured a rare case, representing as it does a house built about the same time as the one shown in Fig. 3. There are two flues in this

Fig. 3—House Showing Tops Tipped Away from Each Other

Fig. 4—Chimney Showing Bend Over the Narrow Side

Why the Chimney Tops Overhang—Two Very Interesting Examples

such a top are but seldom connected with the outer wall and no amount of expansion of these joints will bend the shaft. The expansion must be in the joints of the outer wall to have this effect.

In the earliest frame structures in this country the chimneys were huge affairs, often 6 to 8 ft. square at the base, with tops $3\frac{1}{2}$ ft. square above the roof and having four to six flues. It is evident that the flue in general use must come in a corner or center of this top, and the outer wall at best only made one-half of the flue and was but a small part of the top, so that its bulk resisted the tipping effect and the chimneys remained fairly erect.

The picture, Fig. 1, shows one of these old seventeenth century settlers with large chimneys. From this house George Jacobs, a victim of the Salem witchcraft delusion, was in 1692 taken to be executed. The house has always been used as a habitation, and it is interesting to note how sturdy and erect it is. There is no knowing how many years

chimney, 16 x 36 in., but the bend is over the narrow side. The flue mostly used is the right-hand one. These joints, damaged by the creosote, expand with the frost and tip the 36-in. side, as seen, toward the east. In the nineteenth century many chimneys were built with single flue, and satisfactorily answered for several fittings. One has only to look about and see everywhere how they bend and the direction. When the bend is in a direction other than that opposite the cold quarter, look for the cause.

The corners of a rectangle act as a buttress and prevent the leaning in one fixed direction; therefore, the bend is over the side most nearly opposite the cold quarter, which may vary about a quarter of a circle. Doubtless, if chimneys were built circular in shape, both inside and outside, the lean would be in the same direction in a given locality, except where some protection is found to shield it from the cold air. This we occasionally see in the single-flue top when it leans west or north.

Some Comments on Mortar for Brick Work

From Norman G. Hough, Pittsburgh, Pa.—The writer has read with a great deal of interest Mr. W. H. Hefelfinger's treatise on mortars for brick and stone masonry in the last issue of your publication, and has noticed in particular his statements relative to lime. We feel that in treating this particular phase of the subject Mr. Hefelfinger has unintentionally made certain statements which may have a tendency to place some of the best known brands of lime in disfavor in the building world. This letter is therefore prompted with the idea of correcting any erroneous impressions that might be formed by anyone reading Mr. Hefelfinger's article.

The statement is made that "We must take lime as it comes." The American Society for Testing Materials has standard specifications covering both quicklime and hydrated lime, and it is unnecessary to take lime as it comes but rather orders may be placed for lime that will pass the American Society for Testing Materials specifications, and the buyer may rest assured that he is getting a material which is manufactured in a highly scientific manner, and is a material which will do the work he anticipates. The American Society for Testing Materials has set a standard for manufacturers of this commodity, and the manufacturers are producing materials which will meet the set standard.

The statement is also made that any magnesium carbonate contained by limestone is classed as an impurity. Further, statement is made that some limes contain 35 per cent magnesium carbonate, and that this makes it a poor lime and also that this impurity can be considered only as an adulterant. Lime which is manufactured to meet the A. S. T. M. specifications contains no magnesium carbonate. Upon proper burning of limestone, the magnesium carbonate changes to magnesium oxide. By referring to the A. S. T. M. specifications for lime one finds that the magnesium oxide is not classed as an impurity and cannot be so considered. The magnesium oxide in the mortar, contrary to Mr. Hefelfinger's statement, does undergo chemical change by absorbing carbon dioxide from the atmosphere in the same manner as does the calcium oxide, thus reverting back to magnesium carbonate, which has a value in giving strength to the mortar.

Referring now to the statement that lime containing 35 per cent magnesia is what is known as a poor lime. The fact of whether or not a lime is rich or lean is determined, not so much by the chemical analysis, but by the working quality of the lime. The term "fat" is employed by users of lime more to describe the working qualities of the lime.

In stating the characteristics which a good lime should possess, Characteristic No. 1, according to the author's statement, made earlier in his article, bars from use some of the best limes in the market.

The first requirement reads as follows: "Freedom from clinkers and cinders and with only a small percentage of other impurities." Earlier in his article Mr. Hefelfinger states that magnesium carbonate in lime is an impurity; we have already shown that magnesium carbonate upon burning, becomes magnesium oxide and this is not an impurity, but wish to go one step further and state that tons of lime high in magnesium oxide are being sold daily, and

we have yet to learn of a case where it is not performing the functions for which it was purchased. What the author probably refers to is aluminum, iron, and silicon.

Characteristic No. 2 states that the lime should be free from dust. All limes, either quick or hydrated, are dusty and would not be classed as good limes if they were not so.

Characteristic No. 4 states that the lime should dissolve in soft water. All limes made to meet the American Society for Testing Materials specifications will dissolve in water, either hard or soft.

The statement is also made that poor limes may be used for mortar for brick and stone work, but should not be used for plastering. Earlier in his article the author defines a poor lime as one containing a large percentage of magnesium oxide. At nearly every builders' supply house east of the Mississippi River, also many cities west of the river, one will learn upon inquiry that high magnesium limes are being used for plastering. We can point out many jobs to the author which are at this time being plastered with high magnesium limes, for scratch, brown and finish coats. Some of the best known brands on the market to-day are high magnesium limes and are being sold for plastering purposes.

While on the subject of mortar for brick work, it is in order to call attention to the results of an investigation conducted at Columbia University by James S. Macgregor, professor of civil engineering, in which is determined conclusively the most economical mortar to use, together with the highest construction value.

Water-Proofing Joints in Granite Coping Stones

From M. C. F., Roanoke, Va.—Will some of the practical readers tell me the best packing for joints in granite coping stones? I have used cement in packing joints of this work, but find that there is more or less leakage, causing discoloration of the work below the coping. This is very undesirable, as might naturally be supposed, and if anyone can suggest a remedy I shall be very glad to have the information. It must be understood that the contraction of the stone and the cement is not equal, thereby causing the separation of the two materials.

Cleaning an Oil Stone

From A. J., Milwaukee, Wis.—Kindly give me a method of cleaning an oil stone. A carpenter told me to burn the stone out in fire, and I wish to know if fire will do any harm to the stone?

Answer.—Various methods of cleaning an oil stone have been suggested by readers from time to time in some of the back numbers of THE BUILDING AGE. One suggests that the stone may be heated in an oven until the oil has all oozed out and then wipe it off with a clean rag. Boiling in soft water for about 30 minutes is another method, while several readers have stated that good results may be obtained by boiling the stone three or four hours in concentrated lye. Others, however, object to this as tending to disintegrate the materials of which the stone is composed.

Another way is to cover the stone all around with about a 2-in. thickness of soft clay, packed tightly; then place the stone in a hot oven.

All these methods are claimed to remove the bits of steel which have entered the pores of the stone, causing it to glaze. If the correspondent above will carefully wipe his stone with a clean rag after using, so as to clean off the bits of steel and keep them out of the stone, it will not glaze or dull so quickly as it will without proper care.

Criticism of Ten-Room House

From Arthur Weindorf, Long Island City, N. Y.—I have carefully read what the correspondent signing himself "Ten-room Twin House" has to say on page 54 of the May issue of *THE BUILDING AGE*, and in reply to his invitation to criticise his plans and elevation I suggest that the front wall be built of hollow tile or concrete blocks and finished flat with stucco. This will avoid that cold effect generally seen in the use of concrete blocks. The only place I would use them is for factory construction, where they fit admirably.

A better effect will also be had on the exterior and interior by grouping the windows as shown on the sketches. I also suggest, if possible, keeping the entrances apart, as this will give more privacy

metal, which materials lend themselves more readily to this manner of forms and decoration.

In the elevations I have submitted, dark green tiles or tapestry brick can be set in the surfaces above the second-story window head course to give sufficient decorative treatment.

The top window sashes can be divided as shown to give detail to the window openings.

The roof coping can be cast and extend 1 ft. 4 in. over the face of the building. The second story window head course should project $\frac{3}{4}$ in. This band, the entrance porch and roof coping, with

Profile of Front Wall and Entrance Shown Below

Preferable Arrangement of Front Entrances

Another Method of Grouping the Windows and Entrances

Criticism of Ten-Room House by Arthur Weindorf

to each tenant. This arrangement will require the plans to be reversed, bringing all the plumbing together, where all fixtures from both apartments can be connected to one line of plumbing and reducing the cost of it a trifle.

I do not advise casting in concrete the moldings, cornices, dentils, columns, caps, etc., as he suggests, as concrete does not lend itself readily to this form of construction, and it can only be done by building elaborate and expensive "forms." The material itself suggests broad surfaces and simple big masses and it should only be used in this manner to achieve the most effective architectural results. If detail must be added, this can be done by paneling and the inlaying of colored tiles or tapestry bricks, which will greatly enrich the surfaces.

In the use of concrete to cast molds and decorative surfaces, there is always lacking the artistic effect that one sees in the use of stone, wood and

the spots of colored tile above, will be sufficient to break up the surface of the wall and give the facade that simplicity of design that is not tiresome to the eye.

Average Day's Work for the Carpenter

From O. K., Wapinitia, Ore.—The builder from Danville, while asking the question, "What Is an Average Day's Work," says that time and experience have not demonstrated the answer to his satisfaction. Expressing my sentiments I would say "the same right back at you, brother builder." If a satisfactory average could be found for one locality, it is very probable that it would not apply to some other owing to the difference in materials. I have worked in Wisconsin where our framing lumber was oak and maple that was well seasoned. There we bored a hole in the end of the hammer handle, filled

it with wagon grease and dipped the point of the nail in the grease before we started to drive it.

Then, too, I have worked in Colorado where the framing was all white pine. Some difference there, I can tell you.

Some jobs we secure we know beforehand that the work must be well and carefully done while in the case of others the customers do not expect to pay for first-class work. Some of the articles Mr. Hobart has been contributing will illustrate this.

Another point, and it is an important one in this connection, is that some days you are feeling just right, you whistle all day long and without paying very much attention to what you are doing you turn off an amount of work that surprises you and you are not especially tired either.

Again, you get hold of the wrong end of everything. You do not whistle, but concentrate your mind to the task and work as hard as you can. When night comes you are almost too tired to go home and you have not near come up to your average. You do not understand why; neither do I, but I guess it happens to all of us.

In looking back over my volumes of THE BUILDING AGE I find where one man put on 240 ft. B.M. of shiplap siding and the next day put on 500 ft. Some time ago I was looking after a job where I had twelve carpenters working. There were two of that number whom I noticed in particular for where one was slow the other was fast, and *vice versa*.

When it came to laying floor, $3\frac{1}{4}$ -in. tongued and grooved floor over a subfloor, with deadening felt between, Ed. would lay $3\frac{1}{2}$ squares a day, but 2 squares was the best Billy could do. On the other hand when it came to hanging doors Billy averaged 9 every day while 6 was the most that Ed hung in any day. The doors were from 2 ft. x 6 ft., up to 2 ft. 8 in. x 6 ft. 8 in., made of fir of five-cross panel variety $1\frac{3}{8}$ in. thick, and were hung with two $3\frac{1}{2}$ x $3\frac{1}{2}$ butts, which is the standard for all inside doors out here. This did not include putting on the locks.

There were 136 2-lt. windows in that building and Billy put in the most of them. He averaged sixteen a day.

So, I say, study your men. Where you find that a man is fast you will generally find that he likes that particular part of the work and that he does it well.

I had one man who could fit and hang sixteen doors in eight hours, although eight are considered a day's work—five if you put on the locks.

In making frames for windows to be hung with weights I can make one frame every hour and have found fellows who could beat that.

For the rest of it I will just about agree with "Contractor" from Moffitsville in the February issue although he gives a pretty wide latitude between some of his figures.

Let some one else tell us just what is the average.

Bevel for Rafters and Hoppers

From H. B. W., Washington, D. C.—In examining the diagrams on page 40 of the May issue of THE BUILDING AGE I find that a misprint occurs in connection with Fig. 4, that is O—M should be at right angles to B—O instead of on the line R—O.

An Hotel of Mammoth Proportions

Arrangements have recently been completed for the erection of a twenty-story hotel in New York City which will embody features of unusual interest to the building and architectural fraternity. Active operations are now under way and it is hoped to have the structure ready for occupancy before the close of next year. It will be built of granite and cream-colored brick and will harmonize in a general way with the mammoth Pennsylvania station, which it will face on Seventh Avenue. Above the three lower floors the building will be divided into four units, each a complete structure in itself measuring 54 ft. wide by 200 ft. in length and containing more than 500 rooms, so that the total accommodations will be something like 2200 rooms.

The four units will be connected by three smaller ones 50 ft. wide and 40 ft. long at a point about 90 ft. north of the Thirty-second Street frontage of the building. By this arrangement four large courts will be provided on the Thirty-second Street side of the building and four smaller ones on the Thirty-third Street side, thus giving every room natural light and air. The openings into the building from Thirty-third Street will be 40 ft. wide and 62 ft. long. The reason for the longer courts is to make the most of the southern exposure.

At the extreme end of the building will be another unit, but of smaller dimensions than those to the west. This unit will be 27 ft. wide, 200 ft. deep and nine stories high, and contain 250 rooms which will be set aside for the use of the large force of help necessary to run the hotel.

The main entrance will be through a series of six giant columns, three stories high, and will be the same as those in the colonnade of the railway station on the opposite side of the avenue. The six large columns will support a wide stone balcony which will be planted with hardy shrubbery and winter plants. There will also be five other entrances to the building, but none so imposing as the main approach.

The main floor of the building will have an area of 27,000 sq. ft. and all but 6000 sq. ft. of it will be required for the dining room, tea room and the palm room. There will be no great lobby as in other hotels, but there will be a number of settees and lounges on the floor overlooking the main entrance hall.

It is the present intention to build the main section of the structure, that is, the first three floors, and only two of the four large units, this portion of the work being estimated to involve an outlay of about \$5,000,000. When the business of the hotel is such as to require the other two units they will be constructed upon the base section. It is estimated that the last two units will probably cost \$3,000,000.

It will be known as the Hotel Pennsylvania, and the design is that of the well-known New York architects, McKim, Mead & White.

Several palatial residences are in course of construction in the Great Neck section of Long Island, N. Y., involving an outlay of about \$5,000,000.

Design of Beams, Girders and Trusses*

A Series of Articles on the Above Subjects in
Which Only Arithmetic Is Used for the Calculations

BY ERNEST McCULLOUGH, C.E.

IN the Warren truss, Fig. 66, the stresses in the web members are alternately tension and compression, the light lines indicating tension and the heavy lines compression. Each panel is an equilateral triangle and in the figure the truss is a single system. By using another set of triangles and placing the trusses side by side so one triangle overlaps another by half the width we obtain a double system. Similarly we may use a triple system or a four system truss. When two or more systems are used the result is a Latticed Truss, Fig. 67.

Let W = total load on the truss, uniformly distributed.

P = load on each triangle.

n = number of triangles in the primary single system.

Then, in a single system truss, $P = \frac{W}{n}$

Fig. 66—Examples of Warren Trusses

figured as a frame, and the combined strength of the systems determines the strength of the completed truss. The systems are connected together at every joint where the members meet or cross. The lower apices are the panel joints when the load is on the lower chord, and the upper apices are the panel joints when the load is on the upper chord.

In Fig. 66 (a) the load is on the lower chord and (b) the load is on the upper chord. The truss is here assumed to be uniformly and symmetrically loaded. Coefficients may be written by starting from the center line of the span. On the upper and lower chords are placed the summation of the coefficients for the chords in the respective panels. In Fig. 66 (a) the coefficient for L_oL_1 is one-half that for U_1U_2 , and in (b) the coefficient for U_oU_1 is one-half that for L_1L_2 . The dotted parallelograms at L_o and L_1 , and U_o and U_1 , represent to scale the panel load set off vertically, with the parallelogram of forces completed by drawing horizontal lines to intersect the triangles. Then a = stress on U_1U_2 , = stress on L_1L_2 . It is twice b which represents the stress on U_oU_1 and L_oL_1 . The thrust of the brace U_1L_o = the pull of the tie U_oL_1 . It is resolved at the point of support on the abutment into a horizontal component along the chord, and a downward vertical component, which latter is resisted by the upward reaction of the abutment.

A usual ratio of depth to span in trusses is one-tenth, but circumstances may alter this. It may be used in the absence of computations to ascertain

Fig. 67—Two-system Warren Truss or Lattice Girder

Design of Beams, Girders and Trusses

In a double system truss, $P = \frac{W}{(2n) - 1}$

In a triple system truss, $P = \frac{W}{(3n) - 1}$

In a four system truss, $P = \frac{W}{(4n) - 1}$

Having found the panel load, P , each system is

Note in this series of articles no algebra is used. The rules are written in the modern way in the shape of formulas by using letters instead of writing in full words that are often employed. The words for which the letters stand are explained for every formula so that readers may in time understand how to read and comprehend formulas used by other writers. The actual computation is arithmetical and worked examples are given.—Editor.

the economic depth and economic ratio of depth to span. For Howe trusses the best angle for the diagonals is 45 deg. When any different angle, which indicates a panel length greater or less than the depth, is adopted, the Pratt truss is better. For trusses of the Warren type the angle should be 60 deg.

Deflection is usually taken care of by making the horizontal panel length at the upper end $\frac{1}{8}$ in. longer than the horizontal panel length at the lower end in every 10 ft. of span. This does not alter the lengths of the verticals, but does alter the lengths of diagonals, and when the truss is in place the bottom chord will be cambered upward. Were it perfectly straight it would appear to the eye to sag.

*Continued from page 53 of the May issue.

The amount of camber in inches is found as follows:

d = depth of truss in inches.

s = span of chord in inches.

c = camber in inches.

$$c = \frac{8d}{s}$$

In some of the figures of trusses the spaces are lettered. This is the system introduced by Mr. Bow for the graphical analysis of frames. The member is indicated by the letters between which it lies. In addition to this system of lettering the spaces the joints are sometimes numbered. The spaces are lettered to identify the member in the graphical analysis and the joints are numbered only when the detail drawing of the joint is to be referred to. Some of the trusses shown have the joints lettered with a capital *U* on the upper chord and a capital *L* on the lower chord. The subscript figure represents the number of the joint from the left end, the joint, or joints, at the abutments being *O*. In the drawings a joint is referred to by the *U* or *L*, and the subscript indicating the number of the joint. A

member is identified by giving the letter and subscript number of the joint at each end of the member. This method of identifying joints and members is common.

Architects and designers of buildings have to deal with the simpler forms of trusses, but when it is desirable to introduce maximum economy into a design that truss is most economical in which the stresses in the chords are constant from end to end. This points to a truss having the general outline of a bow string girder. The top chord should be straight and not curved between joints. To obtain a curved outline for a roof it is easy to use fillers or vary the depths of the purlins resting on the trusses. For an exposed chord where the polygonal form would be unsightly the expedient is sometimes adopted of curving the segments, thereby introducing bent beams with arching action. This should never be done. It is better to use a false curved chord in segments to hide the short straight pieces.

(To be continued)

Mortars for Brick and Stone Masonry

Brief Reference to the Chief Characteristics of the Ingredients Entering Into Their Composition

By W. H. HEFELFINGER

MORTAR may be divided into three classes, namely: cement mortar, cement-lime mortar and lime mortar. Cement mortar is strongest and best for any kind of work except for fire brick, but, owing to its cost, is only used in the best work and such work as sewers, foundations and work that requires waterproof mortar. Another reason pure cement mortar is not used more is because it is hard to use, especially in laying brick, but by adding some lime it becomes plastic and works easily. This is called cement-lime mortar, and is used in all buildings of any importance, especially those over two or three stories in height. Lime mortar is used chiefly in cheap dwelling construction, flats and small work not over two or three stories high. Lime mortar sets slowly, and in a building of any height, the weight of the walls would cause considerable settlement in the mortar. Portland cement cannot be used very economically in mixtures containing more than three parts sand to one of cement, except in stone work, where four to one may be used. Two parts sand to one of cement works very well. The proper way to make cement mortar is to first mix the sand and cement together dry and then add water and mix to right consistency. No more should be mixed at a time than can be used in three-quarters of an hour, as rettempering after that decreases the strength.

(Continued from page 50, May issue)

The proportions of cement-lime mortar vary considerably, depending on the work to be done. They may be any proportion between 1 cement, 1/10 lime and 3 sand, to 1/10 cement, 1 of lime and 3 sand. The addition of lime up to about 10 per cent seems to add strength to the mortar, but after that lime weakens the mortar. The main thing to remember in cement-lime mortar is to get the materials thoroughly mixed. The cement should first be mixed with the sand and then the lime added. Never add cement to lime mortar, as it is very hard to get it thoroughly mixed. Hydrated lime works better than lime putty in making cement-lime mortar, as it may be mixed dry with the cement and sand, but one drawback to hydrated lime is that it sets up quickly. Architects and superintendents always have trouble in getting cement-lime mortar mixed to specifications, as it can readily be changed and they cannot tell from the appearance.

Lime mortar, being the cheapest, is used on all cheap work and is often very poor stuff. Lime should be slaked and allowed to cool before sand is added, so it will have a chance to slake thoroughly. The amount of sand that can be added depends upon the quality of the lime. Some lime will carry considerably more sand than others. The usual proportions are about three parts of sand to one of lime, but with good fat lime four to one may be used. The usual practice is to add sand till the mortar will just leave the hoe; rich mortar sticks to the hoe.

The common practice in the East is to make two

kinds of mortar, a face mortar, and a rough mortar for backing up (that is, for brick work). The face mortar is made of bar sand, about three to one for spread work and about two to one for buttered work. The rough mortar is made of bank sand, quite often, from the excavation, and is made as poor as possible. Of course, this is only for cheap work. Sand is usually screened on a ¼-in. screen, and for all ordinary work this will be fine enough, but for work requiring tight joints it should be re-screened on an ⅛-in. mesh screen, and for stock brick it should be still finer. Mortar for stock brick is made of screened lime putty and marble dust, or fine white sand in proportions of one of lime to one of sand. In making mortar for the large, rough joint, a somewhat different formula should be used. It is almost impossible to make a 1-in. joint with ordinary mortar. To make mortar of this kind, grit should be used.

Grit is that part of gravel or crushed stone which will not pass through a ⅛-in. mesh screen and may be almost any size, although ½-in. is about the coarsest that is ever used. The size of the grit should be about one-half the size of the joint. A formula that has been recommended by manufacturers of tapestry brick is as follows: Grit, 2 parts; coarse sand, 5 parts; cement, 1 part; lime putty, ½ part. In making mortar for heavy joints where grit is used, the proportions should always be definite; by that I mean, you should not take for granted that the coarse sand you are using has enough grit in it. It should be screened and the right amount of grit added to the mortar. In all cement-lime and cement mortar the different materials should be accurately proportioned by means of measuring boxes, and not mixed by guesswork. Lime mortar may be gaged quite accurately without use of measuring box.

In making colored mortar great care should be taken to see that different batches are mixed exactly alike, or it will show different shades in the wall. It is hard to state just the amount of mortar color that should be used in order to give a desired color, as mortar colors are not all of the same quality. Much better results can be obtained with paste colors than with those in powder form. Never mix mortar color with hot lime; it should always be cold, as hot lime fades the color. The best results in lime mortar are obtained by mixing the color paste with the sand and then the lime putty. Nearly all builders have trouble with mortar colors, as they fade so easily. It has been my experience that a brown mortar is far better for red brick than red. The red always fades; a little lampblack in red color helps it a lot. Black color fades to a sort of blue color. The best result with black color is obtained by laying up the wall with ordinary mortar, raking it out, and tuck pointing it with black mortar. Use plenty of color in this mortar. I have got good results with black color by using one-eighth as much color as mortar, but this makes it expensive.

Mortar for stone is practically the same as for brick, with the exception that it is mixed much stiffer. For rough stone work the sand is not screened finer than ¼ in. Mortar for ashlar requires sand that has been screened on at least a No. 6 sieve. Portland cement cannot be used very well in laying limestone or sandstone ashlar, as it stains the stone. White Portland, Puzzolan, La-

Farges and other non-staining cements are used for this purpose. Limestone ashlar should be plastered up in the back before it is backed up with stone or brick to keep cement from staining stone. Colored mortar in stone work is always tuck pointed.

Mortar for laying hollow tile should be strong and plastic, so it will stick to the tile. A cement mortar with considerable lime works best. For laying cement blocks a waterproof mortar is often necessary. This requires a rich cement mortar, gaged with lime to make it work smoothly. Use good clean sand, fresh cement, fresh lime and clean water. Mix thoroughly, and be sure your propor-

Notes on Table:															
1- Either fine sand or marble dust may be used.															
2- White Portland Cement.															
3- To make red mortar use just red color. The same with other colors. Only use one color.															
4- Use all the colors given in these.															
4- These proportions are recommended by the manufacturers of Tapestry Brick for their brick.															
5- The proportions given under black are for Germantown lampblack.															

Table to Serve as a Guide in Making Mortar

tions suit the kind of work you expect to do. The table given herewith will serve as a guide in making mortar for almost any purpose.

Mammoth Warehouse for Los Angeles

Work on one of the most ambitious warehouse plans ever undertaken on the Pacific Coast is about to be commenced by the Los Angeles Union Terminal Company. The projected buildings, which will be practically one structure, will cover most of a 32-acre tract, and a very elaborate system of spur tracks and subsidiary transportation devices has been planned in conjunction with the project. The work of demolishing the buildings which now occupy the ground has just been started. There are eighty-four buildings to be removed, including a brick warehouse, a church, several hotels and apartments, and a number of dwellings.

Rise from Carpenter to Contractor*

Some Timely Comments on a Phase of the Building Business Which Will Appeal to Many

BY GEORGE E. WALSH

A CARPENTER is a mechanic who receives from \$3 to \$5 a day, depending upon the part of the country in which he lives, except when he is laid off for lack of work, and then he gets nothing, while the cost of living goes on as before. Why be a carpenter when so many other opportunities offer fame and fortune?

A building contractor is a man who may or may not have been a carpenter, yet he is a man who understands building methods from the foundation up, and who gets anywhere from a thousand or two a year to twenty times two thousand. Then why not be a contractor, and let carpentry go to the smaller man?

There is no short and easy road to success in any line. If so we'd all be at the top, and there'd be no one to do the drudgery of the world in the lower positions. All things must have a beginning, and if one is not willing to begin at the foot of the ladder the chances are that when the opportunity comes he is unable to grasp it.

In years gone by boys were apprenticed to trades, and there was no higher or nobler calling than that of a mechanic. He was always sure of a good living, with a little over. But in recent years there has grown up a tendency to shun the skilled trades. Boys are trained for the law, medicine, ministry or business, and the mechanic's trade is growing less and less attractive. The cry is that there are not enough skilled men to do the world's work thoroughly, and as a result a lot of half-trained mechanics are crowding the field.

Now carpentry is one of the oldest and noblest professions. The boy trained for it need not be ashamed of his position in the world. But what opportunities present themselves to him? In this age of progress and great fortunes one does not want to be limited to \$3 or \$5 a day. If there is no further inducement, the reason is plain why so few take to the skilled trades.

That is the crux of the whole question. Has the boy who chooses carpentry as his life work an opportunity to rise to a position of wealth and influence? There are not wanting many carpenters who will answer this question in the negative, and many others who will smile and say: "It all depends."

Recently I had a long talk with one of the biggest builders of the country. Annually his firm contracts for and puts up buildings worth twenty million dollars, and his profits are so large that it would take a pretty smart lawyer or doctor to make half as much an income.

Yet this man began life as an humble carpenter. He learned the trade, and worked at \$1.50 a day, then \$2.50, and finally reached \$5.

*Cartoons by Chas. M. Hirschfelder.

He was married when he was in the latter class, but he had saved up \$500, and had been studying and learning all the time. He had decided that if he always worked for others he would never get any higher. So he concluded to branch out for himself.

In his small town a dozen buildings were erected in the course of a year. He decided that he would like to build some of these. One day he made a bid for one of the smallest of the new houses going up, costing \$2,000 in all. It was a modest structure, but the man had figured on it carefully. He was contractor and builder all in one. With the exception of employing a fellow-carpenter to assist in some minor points he did the whole thing. He put more time and careful attention into it than most builders, and as a result he finished a good job and cut down his profits so that he cleared less than \$150. He worked three months at it, and cleared less than he could have made if he had stuck to his job at working for others.

But the house stood as an advertisement for him. It was so well built that he got the reputation of building well. So when he put in a bid for another house he got the contract, although his bid was for a few dollars higher than his competitor. The contract was awarded to him because of the merits of his first job. Good workmanship proved its own reward. The second house netted him a fair profit, but the work was performed with equal skill. Before this was finished he had the contract signed for a third, and had to employ two carpenters to help him. Then a fourth came to him, and he added three more men to his working force.

By this time he decided to go into the building and contracting business, and he spent his nights poring over blue prints, books and specifications. Often he figured far into the middle of the night, and then verified his conclusions the next day when his mind was clearer. Within five years he was the leading builder of his town, and then, wishing to conquer more fields, he cast around for work in neighboring towns.

The same systematic business methods, and close

OFTEN HE FIGURED FAR INTO THE MIDDLE OF THE NIGHT.

several offices. Scores of men were working under him. From the small towns he reached out to the city, and in time mastered the problems there. To-day his business extends to half a dozen cities, and he employs nearly 500 men in one capacity and another.

This story of one man's success is merely typical of many others. Out of a list of 500 builders and contractors, 420 started life as carpenters. They learned their trade at the bench, mastered it in every detail, and then advanced step by step to building and contracting. Out

of 50 failures last year of contractors and builders, 40 had never learned the carpenter's trade. They drifted into the business through other avenues. Not understanding the building trade from the foundation up, they were at the mercy of unscrupulous employees. The latter skimmed their work, robbed their employers, and covered up artfully poor work that an expert only could detect. The contractors failed largely because they did not understand the foundation principles of their business.

We spend nearly a billion dollars a year in houses, stores, apartments, hotels and other structures. It is one of the biggest and most progressive businesses of the country, and instead of declining it must continue to increase with the growth of

the country. In the single city of New York housing facilities must be provided annually for an increased population of about 200,000. For the whole country there must be houses and buildings erected to accommodate a million or more. Who are to build these structures?

The opportunities are almost unlimited. New men must constantly come forward to carry on the work. A certain amount of capital is required to enter the building business, but not more than a good carpenter can save up in the course of a few years. To the builder credit is worth more than capital. In his home town it is a simple matter for the man who always pays his bills to get credit for lumber and building materials.

Here is an illustration of how one carpenter got his first start through credit. He had saved up \$200. Then one day he got the opportunity to build a small structure costing \$2,500, payments to be made in three equal installments. He went to the local dealer in lumber and building materials and showed him the contract. He promised to pay \$100 down, and the balance as his payments came due. The dealer instead of turning him down was only too glad to get his trade, and the building materials were delivered as fast as needed. At one time the

"ROBBED THEIR EMPLOYERS,"

THEY DRIFTED

attention to careful work, were given to these outside bids, and when he got a building to put up in a new town he made it a monument to his reputation. One good building, he reasoned, was worth more than columns of advertising. In time his business grew so extensive that he had to have

carpenter was nearly \$1,000 in debt to the dealer, but he made good, paying off the bills as his own payments were made. There is no business where a local carpenter can get credit so easily as when he shows a contract for putting up a house on the time payment. Credit is easily established—if one has the reputation for honesty.

The opportunities in the building and contracting trade are better to-day than ever, and there is no monopoly of the business. It is true that in the big cities companies are organizing to do this work so that on the big jobs the poor man has less chance. But the real opportunities come in the small jobs. In every town and hamlet of the country these opportunities are offered. If one can make good on them he has the wider and greater opportunity that comes from growth and expansion.

Instead of looking down upon and despising the humble trade of the carpenter we might well view it with envious eyes. The skilled carpenter with a gift for organization and system may within a few days become our master and superior. He has the opportunity of making a fortune that is denied nine-tenths of the professional and business men who stick to the old ways. But the man should begin, as a boy, at the bottom, and learn the ropes all the way up. The more thorough the training and experience the better the opportunity of succeeding.

The Need for Better Building Construction

Among the many important matters considered at the twentieth annual meeting of the National Fire Protection Association recently held in Chicago, was that of the need for better building construction, due to the many disastrous fires of the past few months which emphasize the necessity of avoiding the use of combustible materials in the exterior of buildings. The association heartily commended the growing movement for city planning as likely to produce better conditions as to building heights and congested areas, and to provide the open spaces of broad avenues which, in addition to their human and aesthetic values, are excellent checks to sweeping fires.

In its warfare against the needless sacrifice of human lives and property by fire the association advocated ten measures, including the following:

The adoption by municipalities of the Standard Building Code of the National Board of Fire Underwriters to the end that fire resistive building construction may be encouraged, the use of inflammable roof coverings prohibited, adequate exit facilities from buildings assured, and interiors so designed and fire-stopped as to make easy the extinguishment of fires therein.

The adoption by all states of minimum building requirements for the protection of State and County hospitals, asylums and similar institutions outside city limits and of small communities in which the establishment and enforcement of a building code is impracticable.

The adoption of the Association's suggested ordinance providing for the systematic inspection of all buildings by city fire marshals or local firemen to insure the vigorous enforcement of rules for cleanliness, good housekeeping, and the maintenance of safe and unobstructed exits, fire-fighting apparatus and other protective devices.

The wider general use of the automatic sprinkler as a fire extinguishing agent and life saver and the more general adoption of the fire division wall as an important life saving exit facility.

A careful study of the technical surveys of cities made

by the engineers of the Committee on Fire Prevention of the National Board of Fire Underwriters covering the items of water supplies, their adequacy and reliability, fire department efficiency, fire alarm systems and conflagration hazards; and of the possibility of co-operation among neighboring cities through mutual aid and the standardization of hose couplings.

The education of children and the public generally in careful habits regarding the use of fire.

Active Building Season Predicted

"The building business in Indianapolis is recovering from the depression of the last four years, and the outlook for the spring and summer building is encouraging," is the opinion of John Hauck, secretary of the Building Contractors' Association and the Builders' Exchange of Indianapolis, Ind. "Materials, especially all kinds of metals, are high in price because of their demand by war munition factories. Lumber is no higher, however, than it was four years ago. It is not to be anticipated, however, that construction work will reach its highest figures until conditions are normal again."

Modern Open Stair Tenements

Plans are under way looking to the completion of a New York tenement house which will embody the novel feature of the open stairway. As the halls in the majority of tenements are usually dark and unwholesome, the architects have arranged each of the six units of the proposed structure with a large central court as well as street courts on either side of each unit. The stairway, protected from the elements, but open to air and sunshine, is located in this central court and leads to the street through a broad central passage, unobstructed by gate or door. Each tenant will be perfectly isolated after stepping over the threshold of his apartment from the stair court recess, the space usually devoted to stairs and halls being utilized to permit of larger rooms. The plans, which call for an estimated outlay of \$1,000,000, have been prepared by H. A. Smith and W. P. Miller, associated architects, and provide for six six-story units, each with a frontage of 108 ft. The combined units cover an area of about two acres, and provide accommodations for 648 families lodged in suites of two, three and four rooms each with bath. The buildings will be erected in 146th Street, between Seventh and Eighth avenues and will extend through to 147th Street.

New Reinforced Concrete Factory Buildings

A group of reinforced concrete factory buildings with warehouse, garage, etc., is about being erected at Flushing, N. Y., at an estimated cost of \$500,000. The factory buildings will consist of a central craneway 311 ft. long with six two-story buildings at right angles to it and each covering an area of 60 x 150 ft. in size. The architect is Eugene Schoen, 37 Fulton Street, Jamaica, N. Y., and the contract has been awarded to Rheinstein & Haas.

The forty-eighth anniversary exercises of the Hampton Normal & Agricultural Institute, Hampton, Va., were held in the gymnasium on Friday, May 12, with appropriate ceremonies.

Some Things to Know About Chimneys

Results of Personal Observations by a "Chimney Doctor" Who Has Had 23 Years' Experience

BY G. D. CRAIN, JR.

FROM a construction angle the chimney offers no difficulties to the builder. As a structural proposition, a hollow column of brick, with a terra cotta lining, either tied to a wall or free, is an open book to him. He knows that the whole business of chimney construction has been reduced to an exact science. Any handbook will give him the particular formula he wants to guide him in getting the dimensions. As a technical proposition the chimney has been given all the attention coming to it by noted authorities, from Rumford down. But a chimney is not a chimney unless it behaves itself and there are numbers of practical things to know about chimneys not found in books.

Hints by the "Chimney Doctor"

A "chimney doctor" who has spent twenty-three busy years correcting evils of chimney and fireplace construction in his Middle Western home, gave these hints to the writer and he is now passing them on. They are the results of personal experience. Generally, this "chimney doctor" says chimneys built according to standard dimensions and for average uses work satisfactorily. Stock sizes of flue linings and standardization of stove, furnace and other chimney connections contribute to this efficiency. Much of the faulty construction is to be charged to architects long on theory and short on practice. Builders, also, the doctor testifies, in trying to save material and time fall into errors which make trouble afterward and hurt their reputations.

The open fireplace chimney connection is most sinned against, says this doctor, who has treated many cases of throat trouble. Chimneys which serve stoves, furnaces, etc., don't make much trouble, even though they may be stealing a lot of the heat that ought to be radiating, but "the smoke goes up the chimney just the same" and that is the main thing. Whatever may be the builder's own views on the subject, the fact remains that the open fireplace is becoming more and more popular and the majority of new houses have them. Rooms in which they are placed become centers of family life and it is, therefore, highly important that they be well and correctly built.

The Flue Linings

One of the doctor's practical tips is that the dimensions by which flue linings are bought do not describe the area of the flue. For instance, the standard 9 x 9 flue lining does not mean a 9 x 9 flue.

It means a flue as much less than that as the area of a cross-section of the flue. In terra cotta such a flue is 7 x 7 in., not 9 x 9, because the thickness of the flue lining has to be taken off. Terra cotta linings are 1 in. thick; thus 32 sq. in. have to come out of the apparent 81 sq. in. of flue and you have left a flue of 7 x 7, or 49 sq. in. Quite a difference! This means that where an unlined chimney, capable of taking a 9 x 9 flue and sufficiently capacious when unlined, to carry off the smoke from an open fireplace when lined with terra cotta, becomes altogether inadequate to do the work demanded of it.

Chimneys with 9 x 9 Flues

A great deal of this doctor's work results from the fact that builders, as they did in years gone by, build their chimneys with 9 x 9 flues. Now, however, the city's building code calls for flue linings. So these builders put 9 x 9 flues in their 9 x 9 chimneys and they won't do the work required. Then the house owner sends for the chimney surgeon, who has to reduce the throat to correspond to the capacity of the chimney and a big fire in a big fireplace burns with a feeble flicker and little warmth. Pretty soon there are a lot of people saying that "they don't know how to build fireplaces nowadays," and the builder gets blamed.

For all fireplaces with openings up to 32 in., the doctor says, flue linings of 9 x 13 in. should be used. This will insure sufficient draft to carry the smoke and gases up the chimney. If a round lining should be used the inside area should be approximately the same in square inches. Above 30 or 32 in., referring to fireplace openings, he says, the 13 x 13-in. terra cotta linings should be used for ordinary work. This is for fireplaces with openings up to 42 in. For undertakings with larger openings, the builder generally would be following architect's specifications, and the responsibility will rest primarily on the architect, though it would be well for the builder to check these plans because he will have to bear as much of the onus for a fireplace that "smokes" as will the architect.

Position of Rectangular Flue Lining

Another wrinkle is also suggested by the doctor, who says that when a rectangular flue lining, greater in one dimension than in another, is used, the wide side should lie against the chimney breast. For instance, if the lining were to be 9 x 13 in., it should lie with the 13-in. side parallel with the greater width of the mantel and the 9-in. dimension should extend across the wall in which the chimney is built. The principal reason for this disposition of the flue is the effect it will have on the appearance of the

flame in the open fireplace. If the 9-in. width should parallel the firebox, the flame would be contracted as it rose above the fuel; while if the extended opening were provided the flame would spread as it rose and look more as a flame ought to look.

"Make the opening from the fireplace correspond in square inches to the opening at the top of the chimney," is the way the expert referred to states the proposition in everyday figures. That is what he does when he doctors unsuccessful fireplaces. It is a matter of correct adjustment of the firebacks and the shelves at the bottom of the flues, of dampers, sidewalls, etc. Often he finds grates with mouths much too extended. Result: smoky fireplaces and disappointed owners. Another frequent evil this doctor also finds is flues unduly contracted inside the walls, as in cases where these flues are being conducted from fireplaces on both sides of thin walls to flues which rise side by side.

Flues Unduly Contracted

One typical job of this kind occurred in a new house in which were two fireplaces, on opposite sides of a 12-in. wall, both of which smoked when fires were built in them. Both were apparently well constructed; the chimney tops were as they should have been. The trouble was internal. "I took one mantel away; tore out one fireplace and found what I expected," said the expert. "In order to save brick and space in both rooms the architect and builder had tried to crowd both flues into the same 12-in. wall. At the tops of each of the firebacks the throats of the chimneys both sloped backwards necessarily, but before they could be deflected laterally to the line of their respective flues they clashed. At these points, where the throats had been rectangular, they were divided by one row of brick into triangular passages, with the result that each flue was reduced to one-half of the dimensions it should have had. Of course they smoked."

So the expert built an arch from the floor level to the tops of the firebacks. Then one thickness of firebrick was set up for the back of each grate and the sloping firebacks were both set on this single course. Above, where the flues contested for space, they were divided by a single course of brick set edgewise—making a partition 2 in. thick instead of 4, as had been the case, while the gain in condensing the wall between the fireplaces enabled the builder to overcome the lateral deflection in a degree. This cost money, as the expert observed, and was at best flimsy construction, though it gave the house owner fireplaces that would work. If the builder had refused to let himself be persuaded to do what he knew could not be done, he would have saved himself and the architect a black eye apiece.

Elaborate Fireplace With Small Flue

This same expert spoke of numbers of similar instances, referring to an elaborate fireplace in a fine big house, with a costly mantel of Caen stone, wonderfully carved, etc. The fireplace opening is 42 in. and the architect has given that fireplace only a 9 x 9 in. flue which, besides being utterly inadequate, makes two sharp turns in a short space, in order to give the architect what he wanted on the other side of the wall. One thing is sure about this

fireplace, the expert declared. The first time the owners of this mansion build any considerable fire in it they will have a royal big smoke out. Then they will have to tear out the whole side of the room and reconstruct or put in two or three little gas logs and make them answer for their wood fire.

Another thing for the builder to consider is that enough air must be provided to make the draft. The tendency of modern building is to weather strip until not a breath of air can enter. This is excellent inasmuch as it enables the occupants to control means of ventilation, but unless these means are provided, look out for smoky fireplaces. Without it there is no column of cold air to boost the warm air in the chimney. When, as is sometimes the case, it is necessary for the householder to let a certain window down 1 in. from the top in order to keep a fireplace going satisfactorily, either the architect or the builder has slipped up.

Like man, who cannot live to himself alone, chimneys cannot draw to themselves alone. They must be considered in relation to their neighbors. Every builder knows of those which suck as well as those which have too much draft. Their tops should, generally speaking, be on the same level as the tops of those which surround them, or they should be equipped with wind caps, or both. And there are various good things to know about chimneys and fireplaces as to fire prevention. That this is an item worthy of careful study is proven by the large number of fires which are charged to defective flues. The hearth-box is another source of trouble.

"The fireplace for the coal fire, which is elevated in a grate, is safe with a shallower box than the wood-burning fireplace," the expert points out. "This is because the wood fire is burned right on the floor of the fireplace while the coal fire burns on an elevation and there is a non-conducting pan of ashes between it and the floor."

The Shallow Fire Box

And when the chimney builder lets the general contractor dictate a shallow fire box that the builder knows is not safe, he can be sure that the insurance underwriters and the building inspectors will "burn him up" when they investigate the cause of the fire that will be inevitable. When the investigators say to the builder: "You certainly knew that that fireplace was not safe" there is no answer for the builder to make, and he gets another black eye. This is not to say that the builder is under any obligations to censor the specifications of the architect or ride around on a high horse and assert his knowledge about chimneys whenever he does a piece of work. But it often will be to his interest to remember that he is going to have to bear a lot of the criticism that a poorly built chimney or fireplace draws, because he did the work and should have known better.

These suggestions are only the beginning of what the builder can find out for himself about chimneys and fireplaces. No builder can know too much about them and text books are available on all sides. Modern building codes often show an excess of caution, but there will often be builders of houses who want that degree of caution taken in their work. The more the builder knows about chimneys the greater will his field be extended.

Two Frame Cottages of Moderate Cost

Plans of Workingmen's Houses with Some Details of Construction—Cost \$2,300 and \$2,200 Respectively

COTTAGES so arranged as to meet the requirements of workingmen as well as families in moderate circumstances are especially interesting, combining as they often do a compact grouping of rooms with economy of construction. The two examples which we present herewith are intended to be used as homes of this nature, the reader being able to form an excellent idea of their appearance in completed state from the halftone engravings upon this page.

The cottage shown in Fig. 1 is two stories in height, of balloon frame construction and having parlor, living room and kitchen on the first floor, with three bedrooms and bath on the second floor.

hanging newels. The balusters are $1\frac{1}{8}$ in. square.

The foundation walls are built of local stone and pointed both inside and out. The cellar floor is of cement concrete, where so indicated on the foundation plan.

The house is heated by means of hot-air furnace. The range has a place just off the kitchen in what might be regarded as an alcove lighted by a window, but the space is provided with doors so that it may be shut off from the kitchen during warm weather. The hot-water boiler is located in the same place by the side of the range.

The bathroom has a lavatory and medicine cab-

Fig. 1—Frame House Costing About \$2,300

Fig. 2—Frame House Costing About \$2,200

Two Frame Cottages of Moderate Cost—Architect Genaah Jordan, Coopersburg, Pa.

The outside frame is covered with No. 3 North Carolina flooring, the best of the material being sorted out and used for the floors of the house. Over the sheathing boards is placed German siding of white pine $\frac{7}{8}$ in. thick. The roof is of dark blue slate. The gables are shingled and before laying the shingles were stained terra cotta color. The house is painted a light straw color, which contrasts with white trimmings and green blinds.

The inside finish is of yellow pine, the parlor, living room and hall being stained a dark oak. The bedrooms are finished in light oak and the kitchen has a natural finish. The stairway is a closed string with a 6 x 6-in. starting newel and 4 x 4-in.

inet. Soil and vent pipes were put in to save unnecessary expense later on, although bathtub and closet were not installed at the time the house was built. The sink in the kitchen has hot and cold water connections with waste pipe leading to outside drainage pipe. There are also hot and cold-water connections in the cellar.

The plastering is regular three-coat work, the finish coat being a hard white, of plaster of paris, lime putty and pewter sand.

The house was built three years ago at an actual cost of \$2,260, in which is included no contractor's profit. Most of the labor was done by the day or by subcontract.

Foot*Plans, Elevations and Detail of Moderate Cost Frame House Shown in Fig. 1*

Plans, Elevations and Miscellaneous Constructive Details of House Shown in Fig. 2

The cottage shown in Fig. 2 is also a two-story and attic affair of balloon frame construction, the outside frame being sheathed with 1-in. hemlock boards over which is placed a layer of heavy tar felt. The first story has an outside covering of $\frac{7}{8}$ -in. German siding, while the second is covered with $\frac{1}{2}$ x 6-in. spruce siding, there being a belt course between the two styles of siding, as shown in the picture on another page. The roof is of shingles.

The exterior of the first story is painted a pearl gray and the second story an ivory tint, while the trimmings are snuff brown.

The plastering is three-coat work, the same as in the cottage shown in Fig. 1 and the general construction of the two houses is much the same.

In the house shown in Fig. 2 the inside finish is cypress, the dining room, parlor and hall being stained a dark oak.

The foundation walls are concrete "rough cast" on the exterior

tory, but at the time the house was built the closet had not been installed, although soil pipe and vent were put in ready for future connection.

The house was built two years ago at an actual cost of \$2,144, the labor being done by the day or by subcontract. No contractor's profit is included in these figures.

The two houses here shown were designed by Architect Genaah Jordan, Coopersburg, Pa.

A Move for Better Building Construction

Through a co-operative arrangement on lumber specifications and the branding of timber, the Illinois Society of Architects and the manufacturers of Southern pine lumber have taken an important step for the improvement of the quality of future buildings in Chicago and the State of Illinois. The arrangement is of particular importance to Chicago as it is in the metropolitan district that strict specifications for building are most necessary. It is likely, however, that the Illinois action will be taken as

Miscellaneous Constructive Details of Two Frame Cottages of Moderate Cost

while the interior is plastered and whitewashed.

The shape of the house is somewhat different from the other, being much deeper than it is wide and thus calling for a somewhat different arrangement of rooms.

The house is heated by hot-air furnace. The sink in the kitchen has hot and cold-water connections and there are hot and cold-water spigots in the cellar.

The bathroom is provided with bathtub and lava-

a national standard for building codes, and mark a new era in the forcing of proper construction of business buildings, as well as residences.

The nature of the specifications is such that when the architect wants a specific quality of lumber for a building, requiring, for instance, maximum durability and strength, he will specify the use of timber of a special grade, and the manufacturer's brand on this timber will guarantee to the architect that he is giving his client an adequate quality of timber.

The specifications are of interest to owners of buildings, for they will prevent the substitution of inferior lumber.

The form of specifications adopted by the Illinois Society of Architects follows:

For Southern Yellow Pine Structural Timbers

(1) When both maximum durability and strength are required.

Longleaf southern yellow pine of "select structural material" grade in accordance with the definition of "Dense Southern Yellow Pine" as adopted by the American Society for Testing Materials (August, 1915), and the Southern Pine Association ("Density Rule" Book, March 15, 1916). To be dressed to standard sizes conforming to the rules of the Southern Pine Association and branded in accordance with the official requirements of that association.

(2) When strength is required without special reference to durability.

Southern yellow pine of "select structural material" grade as defined in section (1) above. To be dressed to standard sizes conforming to the rules of the Southern Pine Association and branded in accordance with the official requirements of that association.

(3) When used without reference to durability or maximum strength.

No. 1 common southern yellow pine timbers of "dense" grade as defined in the "Timber Rule" book of the Southern Pine Association (March 15, 1916). To be dressed to standard sizes conforming to the rules of the Southern Pine Association.

(4) When used for joists, studs, etc., in ordinary or minor structures without reference to durability or maximum strength.

No. 1 common southern yellow pine, as defined in the "Timber Rule" book of the Southern Pine Association (March 15, 1916). To be dressed in standard sizes conforming to the rules of that association.

For Southern Yellow Pine Heavy Factory and Laminated Flooring

(5) When durability and maximum strength are required.

"Dense" southern yellow pine of "merchantable grade" as defined in the "Timber Rule" book of the Southern Pine Association (March 15, 1916). To be dressed to standard sizes conforming to the rules of that association and branded in accordance with the official requirements of that association.

(6) When strength is required without reference to durability.

Southern yellow pine of "No. 1 common timbers" as defined in the "Timber Rule" book of the Southern Pine Association (March 15, 1916). To be dressed to standard sizes conforming to the rules of that association.

NOTE.—In lieu of the branding of timber above specified, the contractor may, at his option, arrange to have all material furnished under this specification inspected by the inspection department of the Southern Pine Association, in which event the contractor shall furnish and deliver to the architect a certificate showing that all material delivered complies with the architect's specifications. The entire expense of said inspection must be paid by the contractor.

Reinspection

Should the architect demand that any material delivered be reinspected the said inspection shall be made by the official inspectors of the inspection bureau of the Southern Pine Association. Should 95 per cent or more of the material inspected be approved as complying with the grade specified the inspection fee shall be paid by the owner. Should 5 per cent or more of the material inspected be rejected by the said inspector as not complying with said grading rules all inspection fees shall be paid by the contractor.

A Fourteen-Story Studio Building

An improvement which is to replace several buildings in old Washington Square, New York City, is a fourteen-story apartment house designed by and for artists and the cost of which is placed at \$750,000. It is located on the south side of the Square and is the most ambitious apartment house operation which has ever been planned for that old residential section. The project is of the co-operative building type, an arrangement which relieves the owners of the trouble and expense of management and leasing vacancies, and at the same time assures them a definite income.

The new house will cover a plot 70.7 ft. on Washington Square and 164 ft. on Thompson Street. The section facing the square will be devoted exclusively to studio suites for artists, while the remainder of the house facing Thompson Street will be of suites of two to four or six rooms. By the co-operative method each tenant buys his own apartment outright and he can have it planned according to his own ideas if taken before the building is completed. By the interlocking system these studio suites may be duplex or single. This duplex connecting system of living quarters as worked out by Charles W. Buckham, the architect, affords a certain flexibility to increase or decrease the apartment space according to requirements, and it is said to be the first time that such a plan has been worked out with such careful detail.

The building, although fourteen stories, will not exceed in height a total of 150 ft. It will be Gothic in its architecture and the facade will be of light face brick and terra cotta.

The Modern Apartment House

There seems to be no end to the inducements offered by owners of flat buildings to prospective tenants. An interesting folder recently issued in Chicago covering the feature of a court apartment enumerates the following advantages.

Maid service by hour or day.
Grecian café at reasonable prices.
Vacuum cleaners at your own disposal.
Extensive lawns and attractive shrubbery.
Beautiful flowers, tennis courts.
Free swimming pool with heated water, summer and winter.
Finely equipped gymnasium with free instructions in art of fencing and Swedish movements.

The following are classified as innovations:

Disappearing bed in each apartment.
Especially designed consoles. Buffets with plenty of drawer space and shelf room.
Shower baths, mosaic floor and beautiful bathroom equipment.
Steel medicine cabinets, wall safes, out-of-sight garbage receptacles.
Merchandising receiving cases, inside white enameled self-draining refrigerators.
Practical self-lighting gas ranges. Heavy, luxurious Brussels stair carpet used in harmony with the woodwork. Curtain rods and all necessary fixtures to all windows.
White enameled steel kitchen cabinets, sugar and flour receptacles and glass rolling pin; dressing mirror in closet door, electric light fixtures of the latest design.

The architecture is said to be of a new and unique design with sun parlors and private screened sleeping porches, containing apartments of 2, 3, 4, 5 and 6 rooms each. The approaches to this building are by means of beautiful courts and lanes, protected by self-locking front doors with electric openers controlled from each apartment.

New Publications

Paint and Color Mixing. By A. Seymour Jennings, 245 pages, size 5½ x 8½ in. Illustrated with 300 samples of oil- and water-paints and water colors and 1500 different color mixtures. Bound in cloth. Published by Spon & Chamberlain. Price, \$2.

The popularity and practical value of this book have necessitated the publication of a fifth edition, which cannot fail to prove interesting and instructive to the builder or carpenter-contractor who does more or less painting in connection with his regular work, or who is at least interested in knowing the color possibilities of painting. Different colors and their varying tints are exhaustively illustrated, interest being enhanced by the accompanying explanations as to how they are mixed.

The new edition has been enlarged by fifty pages, and the number of plates has been increased from thirteen to seventeen. Color matching has been given more attention than formerly. Other important additions include chapters on "Straining Colors," "Putty Hard Stopping and Brush Filling," as well as "Two Hundred Standardized Colors." Although intended primarily for decorators, the attention that the book has received from paint and color manufacturers caused the author to devote considerable additional space to machinery used in paint and color mixing.

Many readers are doubtless familiar with the material contained in former editions of this work, but those who are not will be interested in learning that the headings for the old chapters cover about everything a man is likely to wish to know about paint.

Architec-tonics—The Tales of Tom Thumtack, Architect. 175 pages; size, 5 x 7 in.; 100 illustrations; bound in cloth. Published by the William T. Comstock Co. Price, \$1.50.

An architect has been able to claim almost everything except a place in literature as a recognized character in fiction. The author of this little book decided to give the architect that honor, treating him with a humor sometimes sarcastic, sometimes sympathetic; but whether it be the architect, his client or the builder who bears the brunt of the author's quiet yet truthful fun-making, the humor is entertaining and at times instructive. It is worth while for a man to once in a while stand back from his work and amuse himself by realizing how funny some of his most aggravating encounters have been. Ability to see the humorous side of a disappointment tempers many a sad misfortune.

Limes and Cements—Their Nature, Manufacture and Use. By Ernest A. Doncaster. 212 pages; 21 illustrations. Published by D. Appleton & Co. Price, \$1.75.

This is an elementary treatise written by an Englishman and is a scholarly compilation of articles contributed by men of many nationalities to periodicals. In this connection it is gratifying to note the list of American works drawn upon.

It should be in the hands of all architects, con-

tractors and engineers. The language is clear, and the absence of terms understandable only to men of college training is marked. It is written for the everyday worker, and covers all the points really necessary for men to know in the daily conduct of business. Practically every question the plasterer, the average cement-worker, brick-mason and carpenter may ask is here answered. The man who likes a more scientific discussion is cared for in references to the sources from which the author drew. It is a fine example of a practical book for practical men written by a conscientious and well-trained student.

Mechanical Drafting. By Charles B. Howe. 147 pages, size 11 x 8 in. Illustrated with 166 photographic views and drawings. Bound in cloth. Published by John Wiley & Sons. Price, \$1.75.

This book has been prepared with a view to supplying the needs of students. The author expresses the belief that "the chief value of a knowledge of mechanical drawing is its utility as a medium of expression." The text and illustrations have therefore been prepared along these lines. The book contains information as to the nature and uses of the instruments required in mechanical drafting; the fundamental principles of drafting and the means by which different materials and construction lines are shown; lettering; geometry of drawing; orthographic projection, etc. Attention is also given to working drawings, machine drawing, plan drawing and photographs of the house and parts constructed from given plans; conventional typographical signs; pictorial representation and sketching, etc. There is a chapter on "Blue Printing," which contains valuable information as to the methods and apparatus employed.

A Novel Architectural Undertaking

Plans and pictures of the Dominion of Versailles, intended to be the biggest architectural feature or mass in America, have been prepared by a well-known firm of architects, who aim to make an American adaptation of the French Chateau de Versailles for residential purposes with a combination of the best elements of city and country life. It will be located on Long Island, four miles beyond the boundary line of Greater New York. The site contains 180 acres, to be laid out in gardens or parks. The chateau is planned to be 1200 ft. in length. The front portions will have an average height of eight stories; rear portions will average sixteen stories, culminating in two towers each 375 ft. high.

A garage is about to be built in Augusta, Kan., covering an area of 50 x 120 ft. and constructed of brick and concrete with a front of pressed brick and plate glass. A gravel roof of the suspension type and containing a large skylight will permit of a display room said to be the largest of its kind, without posts or supports, in Kansas. Back of this room will be a shop and wash room. Architect S. G. Bond has provided plans for a building costing about \$7,000, which will be erected by Schoeb & Middleton.

Current News of Builders' Exchanges

Annual Meetings and New Officers for the Ensuing Year—Banquet of the Grand Rapids Exchange

Banquet of Grand Rapids Exchange

THE members of the Builders' and Traders' Exchange of Grand Rapids, Mich., held their second annual banquet at the Livingston Hotel on the evening of May 3, when fully two hundred, including invited guests—the architects of the city—sat down to the good things which had been provided by the committee in charge of the affair. President Glendon A. Richards of the Exchange presided and Clyde Ross acted as toastmaster. There were a number of speakers and the dominant tone of the addresses was efficiency in business and preparedness for it through public-school education.

The first speaker was S. Eugene Osgood, who had for his topic "The Sky Line of Grand Rapids," and the point was made that the real sky line of the city was not in skyscrapers but in the efficiency of big business that made such structures possible. He declared that the Builders' and Traders' Exchange represents the efficiency sky line of business by the new alliance in preparedness through co-operation; that the Exchange is an organization through which the standard of the sky line of business is being raised. H. W. Faraday of the Emerson Institute responded to the toast, "Fire-proofing Construction and Its Relations to Efficiency." The principal address of the evening, on "Social Preparedness," was by Rev. A. W. Wishart, who pointed out that the American public school is, or should be, the basis of preparedness.

Another pleasant feature of the evening was the presentation by President Richards on behalf of the Builders' and Traders' Exchange of loving cups to S. A. Morman, George C. Schroeder and C. M. Emerson, ex-presidents of the Exchange. During the evening music was rendered by the Livingston Hotel orchestra, and there were violin solos and selections by artists from the Empress Theater.

Pawtucket Builders' and Traders' Exchange

The members of the Builders' and Traders' Exchange of Pawtucket, R. I., held their annual banquet at the To Kalon Club on the evening of Thursday, May 18, when addresses were made by prominent contractors of New England. The committee in charge of the affair consisted of Joseph F. Salisbury, Henry Vigeant and M. T. Keane.

At a recent meeting of the Exchange an agreement with the Carpenters' Union, to go into effect June 1, was ratified. Practically the same schedule that has been in force among the larger contractors during the past year will go into effect and will mean an increase for carpenters employed by the smaller contractors.

Edward A. Collings was recently elected permanent secretary of the Exchange.

Builders' Exchange of North Carolina

The Executive Committee of the Builders' Exchange of North Carolina recently held an important meeting, when plans were commenced for the semi-annual convention of the organization, to be held July 19 and 20 at Wrightsville Beach. It is expected that the meeting this summer will consider many matters of importance to the building business in that State. One of these will undoubtedly be the organization of a general contractors' association, a sub-contractors' association and a material men's association. Each association will meet separately on the first day of the convention and will have its own officers. This arrangement is expected to greatly expedite the work in hand.

Sacramento Builders' Exchange

The new Builders' Exchange at Sacramento, Cal., which formed a temporary organization about the first of the year, has elected a new Board of Directors, which later held a meeting and re-elected the former officers, Fred E. Conners being president. The Exchange now has 110 members.

Ralph McLaren Entertained by New Orleans Exchange

One of the delegates to the recent Baltimore convention of the National Association of Builders' Exchanges was Ralph McLaren, a supervisor of San Francisco and a director of the General Contractors' Association of the latter city. When journeying homeward he went by way of New Orleans, in which city he was the guest of Treasurer James M. McGowan of the Contractors' and Dealers' Exchange of New Orleans. Mr. McLaren was shown the points of interest around the city, taking in the mammoth warehouses along the waterfront, inspecting the purification plant, etc. Mr. McLaren, it may be interesting to state, was one of the men in San Francisco who was at the head of the rat-proofing of his native city, and Mr. McGowan is now devoting a great deal of his time in New Orleans to that important duty.

The Saginaw Builders' Exchange

A meeting designed to promote the interests of the Builders' and Traders' Exchange of Saginaw, Mich., was recently held in Teutonia Hall, when builders and members of allied trades to the number of 100 were present. The Mayor spoke a few words of welcome and alluded to the industrial and civic prosperity of Saginaw. Fred C. Trier, president of the local Exchange, gave an earnest appeal for increased membership and hearty co-operation on the part of all interested. Much of the great success of the evening was due to his efforts.

Those present enjoyed a fine banquet and listened to a number of addresses of Saginaw and State speakers. The toastmaster of the evening was A. W. Tausend, and among those who had something to say were Congressman J. W. Fordney, State President C. S. Wilcox and Secretary Robert K. Orr of Lansing. Mr. Orr referred to the importance of keeping posted on current legislation and suggested that each local take up the matter with its legislators. President Trier invited every builder or firm to join the Exchange, and stated that an office would be opened where sub-contractors could examine plans. He urged a general meeting every quarter.

Master Builders' Exchange of Salt Lake City

Advices from Secretary J. M. Silvers of the Master Builders' Exchange, Continental Bank Building, Salt Lake City, Utah, indicate active preparations for a considerable amount of building this season, the work including all varieties of structures. The Exchange is in a flourishing condition and at the annual meeting of officers for the ensuing year were chosen as follows:

President—J. H. Angel.

Vice-President—Martin Benson.

Secretary—J. M. Silvers.

Treasurer—Augustus Rudine.

An Executive Committee consisting of three members was also chosen, consisting of E. H. Dundas, George R. Cushing and O. Chytraus.

Brief Review of the Building Situation

Building Operations for April in 116 Cities Show
an Increase of 14.22 Per Cent Over April, 1915

THE planning of new construction work throughout the country continues to make a gratifying showing as compared with this season last year, the figures covering 116 cities indicating an increase of 14.22 per cent over April, 1915. As the situation a year ago was practically on an equality with that of April, 1914, and as April of that year showed a loss of 15½ per cent, as compared with April, 1913, it will be seen that present conditions are therefore about normal. It is well known that April marks the beginning of the building season and it is gratifying to note that in all sections of the country from which reports have been received the activity over last year is marked. Conforming to the practice of the immediate past of dividing the country into four zones or sections, it is found that the cities of the East indicate a gain over April last year of 10.16 per cent.

CITIES OF EASTERN STATES

Worcester	556,848	542,860

In what may be designated as the Middle Zone, this embracing the territory west of Pittsburgh and east of Denver, thirty-five cities report an increase in the amount of work planned of 19.59 per cent. Of the cities reporting twenty-three show increases and twelve decreases. Of the former, Chicago, Canton, Columbus, Duluth, Grand Rapids, Indianapolis, Kansas City, Minneapolis, Toledo and Wichita, Kan., are conspicuous, while the more important decreases include Cincinnati, Cleveland, Detroit, Milwaukee, Davenport and Topeka.

CITIES IN MIDDLE STATES

	April, 1916	April, 1915

Youngstown	373,001	219,505

The Southern cities reporting show a greater increase as compared with April last year than any other sections reporting. Here twenty cities indicate a gain of 20.24 per cent, this being brought about by thirteen cities showing increases and seven decreases. Baltimore, Birmingham, Nashville, Norfolk, Oklahoma and Richmond show the greatest gains, while Dallas, Jacksonville, Memphis, New Orleans and Savannah show a falling off in building activity.

CITIES IN SOUTHERN STATES

	April, 1916	April, 1915

Waco, Tex.	52,605	22,575

The section showing the smallest increase over last year is the extreme Western portion of the country, from which come reports from sixteen cities with twelve showing increases and four decreases. The most notable gain is in San Francisco, with Tacoma, San Diego, Oakland, Denver and Fresno ahead of last year. The notable decreases are found in Los Angeles, Seattle and Spokane.

MEDUSA WATERPROOFING

Basement of Treleven Building, Fond du Lac, Wisconsin. Made Water-tight by Medusa Waterproofing

They Didn't Think It Was Possible

"It was the general opinion in Fond du Lac," writes H. T. Liebert, Architect of the Treleven Building, "that you could not get a dry basement in the city if you went below the lake level. But we used your MEDUSA WATER-PROOFED CEMENT and the results have been beyond my expectation. We can strike a match on any portion of inside basement walls as *no moisture comes through them*".

This is but one of the hundreds who testify to the sure results which come from using

Medusa Waterproofing

or

Medusa Waterproofed Cement

Medusa Waterproofing is the *original* concrete waterproofing. It makes concrete, stucco and masonry buildings absolutely damp-proof and weatherproof. It comes in powder or paste form. Two per cent in the mix insures the results you want.

Medusa Waterproofed Cement is a combination of Medusa Cement and Medusa Waterproofing mixed for your convenience at our own factory.

Don't take chances with untested waterproofing. Medusa is used by reliable contractors and engineers everywhere.

See what others have done. Write *today* for booklet "Medusa Waterproofing." It contains pictures of waterproofing jobs that are bound to interest you. Sent to any one on request.

This ROOFING CATALOG

(The Largest and Most Complete Ever Printed)

WILL HELP YOU

The *Rex Products* catalog contains 112 pages and more than 180 pictures and illustrations. Besides complete instructions for laying all styles of asphalt shingles and prepared roofings, you will find in it a full description of each one of the 27 different *Rex Products* which we manufacture. You will also find much helpful information about slate, tile, asbestos shingles, tin and corrugated steel roofings.

We will send you this splendid catalog and a set of samples without cost or obligation to you. Write—

Flintkote Manufacturing Co.

98 Pearl St., Boston, Mass.

1104 Equitable Bldg., New York, N. Y.

651 Peoples Gas Bldg., Chicago, Ill.

Hennen Bldg., New Orleans, La.

REX STRIP SHINGLES

Will not blow up in the wind because the spaces between the shingles do not extend under the shingles in the course above, and so there is no opening for the wind to get under them and lift them. This is why Rex Strip Shingles make a *tighter* roof than any individual shingles.

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Composite Metal Lath

One of the latest candidates to popular favor in the way of a lath for use in connection with building construction is illustrated herewith. It is known as Composite Metal Lath, and is referred to as something of a radical departure in the field, consisting as it does of 19 gauge wire woven in a loom $\frac{3}{4}$ in. mesh and almost completely covered by small crosses of brick clay pressed over the intersection of the wire in design, so as to inclose it, as clearly indicated in Fig. 1, which represents a portion of a sheet of the lath. It is then passed through specially constructed ovens, where it is subjected to a very high degree of temperature, then allowed to cool, after which it is ready for the market. The gage of wire used for the lath is governed by the purpose for which it is to be used, but it has been found by the manufacturers, the Composite Metal Lath Company, 128 Broadway, New York City, that the standard adopted will meet practically all requirements. The thickness of the lath and the form of the bricklets, by which name the clay pressed on to the wire is designated, allow it to be stapled directly to any flat surface,

that it can be used as a self-centering reinforcement for segmental work. As the wire used in the construction of the lath is said to be annealed and highly oxidized in the factory it withstands dampness and is therefore adapted for use in laundries, bathrooms, dye rooms and similar places. It is very flexible, as the bricklets

Fig. 1—The Appearance of the Lath, Practically Full Size

Fig. 3—A Vertical Section, Showing Method of Securing Grounds for Base Board, Chair Rail and Picture Molding

Fig. 2—A Horizontal Section Through a $3\frac{1}{2}$ -In. Partition

Composite Metal Lath—Showing its Appearance and Application

thus avoiding the necessity of furring strips. Figs. 2 and 3 afford an excellent idea of the use of the lath in building construction, representing as they do a horizontal section through a $3\frac{1}{2}$ -in. partition, and a vertical section showing the method of securing grounds for base board, chair rail and picture molding. The point is made that this form of lath is especially well adapted for use in connection with stucco work; is also fire retardent and can be used as a reinforcement for concrete slabs or arches. The claim is also made

or little tile crosses are reduced in thickness at every junction so that they will not crush. The idea of this feature may be gathered from an examination of Fig. 1. Composite Metal Lath is made in 16-ft. lengths 40 in. wide, and is furnished in rolls 40 in. long and 10 in. in diameter, each roll containing 55 sq. ft. and weighing about 55 lbs. The company calls attention to the fact that the lath is not subject to injury in handling or shipping owing to the hardness of the bricklets and the elasticity of the wire.

Rapid Development in Use of Wall Boards

Perhaps with but one exception there is no new use for wood fibers that have made such rapid development in the United States in the past ten years as its use for wall boards. It is stated from what is considered good authority that the consumption of wall board in the United States for the year 1915 was probably in excess of 480,000,000 sq. ft.

The use of wall boards for interior work, in place of lath and plaster, would almost appear to be a new principle in building, and to a certain extent it is. At the same time, we find that the Japanese have employed a board for partitions for perhaps hundreds of years. The Japanese made their boards from a very strong fiber, which they obtained from the tough inner bark of six species of deciduous trees, this inner bark having long, tough, fiber cells. The bark most in use by the Japanese is taken from the mulberry tree. In order to obtain the fibers the bark is boiled in hot water to separate the outer bark from the inner bark. The inner bark is then dried and bundled and shipped to the board maker. The method employed by the Japanese for reducing the inner bark to the pulp form is very primitive. They employ a crude mallet, with which they beat the bark against a flat surface like a flat stone until it is reduced to a pulp. It is then subjected to

of reducing the root is distinctly modern, for in place of the crude method employed by the Japanese the modern method employs chemicals, and the root fiber is put through a process that removes all the pitch starch matter, and all other vegetable matter natural to the fibers, leaving what might be termed a commercially pure cellulose; that is, as one authority states, the plant structure.

This pulp, or more correctly speaking, chemical fiber is by modern machinery manipulated and built up until it is placed on the market in the shape of large panels for interior work.

The product obtained by this latest development in the wall board industry is naturally far superior to the product obtained by the earlier methods employed in the United States for making wall boards, not only from the fact that its raw material is made by the chemical process, therefore making a strong pulp, but objections which earlier products had have been overcome.

Nor has this root fiber product stopped in its development at producing this superior quality of wall board, for it has been found that the root fiber board has certain characteristics that the ground wood boards have not, and by taking advantage of these facts, plus a patented process for indenting or engraving the board, there is now being produced panels in imitation of the

Fig. 4—Living Room of a Cottage at Atlantic Highlands. Showing Ceiling and Side Walls Covered with Wall Board

further beating in water to thoroughly separate the fibers, after which the usual methods of making board by hand are employed. This process was introduced into Japan from Korea about the year 610 A. D., and the board made from this process has been used for partitions between different rooms.

During the development of the wall board industry in the United States the principal raw material used has been mechanical ground wood pulp and old papers. It is, therefore, in line with progress that improvements should develop both in the raw material used and in the method of construction, and it is interesting to note that one of the most recent developments in wall board, which appeared on the market some two and one-half years ago, has followed to a certain extent the raw material employed by the Japanese. In place, however, of the fiber obtained from the inner bark, this modern process uses the fiber obtained from the root of the tree, it having been demonstrated that products made from the root fiber are far stronger than products made from the fibers of the tree itself. The process

real wood veneer panels, and so carefully and completely has this process been worked out that these panels may be finished in the various stains used in finishing the real wood, and so varied are the grains that the real wood and the synthetic wood when placed side by side are practically identical in appearance.

At a recent convention an exhibition prepared by one of the largest varnish and stain manufacturers in the world showing what can be accomplished with this synthetic wood made from root fiber attracted the attention and comments of all, and the fact that panels 10 to 12 feet in length could be made to reproduce the old English and Dutch panels of one to two hundred years ago proved that the effects so much desired by the architect, interior decorator and builder were available. The many possibilities for this new product are evident. It is well adapted for use in churches, theaters and public houses for both walls and ceilings, for commercial houses where wood panel effects for the office and windows are desired, and last and most im-

(Continued on page 84)

Fiberlic For Walls and Ceilings

Features: Fiberlic exclusive features—a wall board made from root fibre, chemically treated to remove from the fibres all the starchy matter that might harbor mould growth, all the resinous matter, thus making it more fire-resisting. It is the only patented chemically treated, long-fibred wall board on the market.

Economy: Fiberlic is not merely a substitute, but a new principle in building, providing as it does a wall or ceiling which will not deteriorate. More economical than lath and plaster, facilitates quick construction and has stood the test of time.

Uses: Fiberlic effectually contributes to good taste in the development of fine interiors. From the viewpoint of utility it serves with equal facility the peculiar needs of Hospitals, Doctors' Offices, Stores, Theatres, and Office Buildings.

Finishes: Fiberlic Paints permit the use of soap and water and scrubbing brush in the removal of stains and dust, thus insuring a permanently clean surface. Fiberlic is susceptible to a variety of finishes and is not restricted to the use of our finishes where something else is preferred.

Data and Samples sent free on request, will serve you advantageously in connection with your building work.

portant, the home builder will well appreciate what this all means when he realizes that the wood panel effects so much desired are now available at prices that vary from 66 2/3 per cent to 150 per cent less than the cost of the wood veneer panels, and in widths and lengths that were only available many years ago when large trees were the rule and not the exception.

New Stanley Garage Door Holder

A device for use in holding open garage doors and of such a nature that it cannot fail to be appreciated by the owner of an automobile, who doubtless has experienced the danger of having the wind suddenly close the open garage door with a bang, thereby injuring his machine, has just been placed upon the market by the Stanley Works, New Britain, Conn., and a general application of which is shown in Fig. 5. It is known as No. 1774, is universal in application, easy to put on and may be used for either right or left-hand doors. It is simple and durable in construction and has but few parts. There is a rigid arm of U-shaped steel with attaching plates of heavy gage and large size, applied at sufficient distance from the hinged joint as to de-

Fig. 5—Showing Application of Stanley Garage Door Holder

velop the maximum of holding power. Its length is 30 in. and the net weight per pair is 8 lb. Reference is made to the fact that a holder of this nature on the garage door serves as inexpensive automobile insurance, saves time in getting the car in and out, and adds to convenience while working in and about the building.

The Kuhn Patent Tongue and Groove Flooring

One of the most interesting developments in connection with floor construction has just been brought to the notice of the trade by The Interior Hardwood Company, 1308 Beecher Street, Indianapolis, Ind., and is known as the Kuhn Patent tongue and groove flooring. The feature of this new and improved flooring is found in the construction of the tongue and groove which is made in bevel form, thus rendering the tongue longer, stronger and with the under side reinforced so that it will not break, it is claimed, when the nail goes through it. The bevel in the new style allows the flooring to be drawn more tightly together besides saving the breaks. As a consequence, it is stated that a man can lay more of it in a day and can do a better job of flooring. It is made from carefully selected hardwood lumber, the claim being made that 80 per cent of it comes in lengths of 8 ft. or over; that no strip is shorter than 4 ft., while the 20 per cent average between 4 ft. and 8 ft. is well above 6 ft. On account of the bevel it is claimed that there is a very material saving over the old style of flooring, as every inch of the material can be used. It is carefully selected as to color and only uniformly colored strips are used. The accuracy of the machine work is said to insure a perfect fitting of each strip—exactly 3/4 by 2-in. face. Kuhn patent flooring

is made in quarter sawed oak, plain sawed white oak, plain sawed red oak, hard white maple, dark mahogany, black walnut, dark cherry and dark oak. The Interior Hardwood Company is sending free to those who desire it a copy of an attractive booklet containing valuable information and suggestions relative to hardwood floors, their making, laying, finishing and care. It is a useful little book for expert builders and contractors, as well as for home-owners.

New Plant of Buffalo Wire Works Company

In order to meet the growing demand for Buffalo wire products the Buffalo Wire Works Company has just moved its entire wire work department to 290 Terrace, corner of Genesee Street, Buffalo, N. Y., in the building formerly occupied by the Buffalo Meter Company. It is a brick structure, 67 x 70 ft. in plan, and five stories in height, giving the company an additional floor space of 25,000 sq. ft. Here the company has installed its wire work machinery for making window guards, desk and counter rails, elevator cabs, fencing, wire signs, ornamental panels, grilles, wickets, folding gates, lockers, tool room enclosures, etc. The new plant, a bird's eye view of which is shown in Fig. 6, practically doubles the company's capacity to manufacture these articles. The removal also enables it to increase the weaving department in the section formerly occupied by the wire work department. The company states that since opening last fall its Philadelphia branch at

Fig. 6—New Plant of Buffalo Wire Works Co.

No. 11 South Seventh Street, it has been compelled to increase its quarters in that city, and it has taken three additional floors at No. 9 South Seventh Street, adjoining the present branch, which gives an additional 10,000 sq. ft. of floor space, thus enabling the company to carry a still larger stock of Buffalo wire products for its customers and patrons in Philadelphia and surrounding territories.

Why a Saw Cuts

The saw has been called the "king of tools," and the important place which it has occupied in building operations from remote ages up to the present day justifies the title. A description of the way it cuts may therefore be of interest to the carpenter who makes use of it. When a knife cuts the edge will merely score to a certain depth and then become wedged or jammed in the wood, unless the latter is of exceedingly thin stock. A chisel, the cutting edge of which is most akin to a saw, separates and removes a long shaving by what may appropriately be termed paring or slitting. A saw combines the action of both knife and chisel, removing successive portions of material, called sawdust, by cutting and tearing. A crosscut handsaw possesses V-shaped teeth, the points set or bent slightly over for clearance of the body of the blade in the kerf; one point to the right, the next to the left, and so on

(Continued on page 88)

Why Your Choice Should Be Kuhn Patent Tongue and Groove Flooring

IN figuring material you can't afford to slight the hardwood floors. The satisfaction which goes with the smooth, even surface and the long-continued wear of every Kuhn Patent Tongue and Groove hardwood floor you lay brings the home-owner's commendation and more business for the contractor. And there is a greater profit for you in every job laid with Kuhn Patent Flooring.

Easiest to Lay

The Right Kind

The Wrong Kind

Notice the difference between the Kuhn Patent Tongue and Groove and the common kind. The Kuhn Tongue is longer and stronger and reinforced on the underside which prevents it from breaking off when nailing. At the same time the bevel makes the flooring draw up more tightly than the ordinary kind and prevents upper lip from breaking. Your men can lay more of it in a day. Adds to your profit.

Long Lengths

Eighty per cent of Kuhn Flooring is in lengths of eight feet or over. There's not a single strip shorter than four feet, and the average of the twenty per cent between four and eight feet is well above six feet.

You, who have probably often paid for the extra labor of finishing floors of short lengths, know what an added profit our long length flooring will give you.

No. 15, 1¾ in. C. C. flooring brads are used in laying.

Face Surface Measurements

When you buy ¾-inch flooring with a 2-inch face, you pay for 2½-inch width of flooring—25% added for the tongue which is lost in laying. When you select Kuhn Patent Tongue and Groove Flooring, you pay only for actual width of the face of the strip.

This saving is another addition to your profits.

Face Absolutely Free From Defects

Every strip of Kuhn Patent Flooring is critically inspected for defects of any kind; all sap, knots or streaks are discarded. Kuhn Flooring is also most carefully sorted for color and only the even colored strips are included. Every inch of Kuhn Flooring can be used—no waste. Still more profit for you.

Accurate Membering

The Kuhn Patent tongue and groove are cut on special flooring machines, which insure accurate membering of pieces. It always fits. Frequent micrometer tests keep the thickness always at exactly three-eighths of an inch and the width of the face at two inches.

Free Flooring Book full of information about making, laying, finishing and care. Suggestions of value even to the most expert builder, contractor, or home-owner. Get your copy now.

THE INTERIOR HARDWOOD CO.
1312 Beecher Street Indianapolis, Ind.

Our flooring gives utmost satisfaction to the home-owner as well as biggest profit to you, because through every process, from the forest to your "job," it is given the same careful handling and treatment. We use most improved machinery for manufacturing our flooring. Our workmen are all thoroughly skilled and competent. Our years of experience have brought us to the most approved methods.

Seasoning

The lumber is yard-seasoned for at least one year and kiln-dried for 30 days before manufacturing and the finished product kept dry in heated warehouses. No swollen tongues in Kuhn Patent Flooring—no split faces.

Kuhn Patent Flooring is made in

Quarter Sawed White Oak	Dark Mahogany
Plain Sawed White Oak	Black Walnut
Plain Sawed Red Oak	Dark Cherry
Hard White Maple	Dark Oak

Our location in the center of the choice hardwood district gives us every advantage for the very cream of quality in these woods, as well as for price and prompt deliveries.

We are also manufacturers of a complete line of beautiful Parquet floors, Borders and Wood Carpet of the very highest quality.

Before making another estimate for hardwood flooring of any kind, mail the coupon or a postal for our

alternately. Although the front and back of each tooth are beveled, it is the outside edge of the front of the point (the portion "set") that does the cutting. Each end of the "V" enters the wood, going deeper as pressure is applied until the cutting edge on the outside front of the points is brought in, the forward motion of the blade causing the points and cutting edges to strike the fibre at right angles to its length, thus severing it from the main body of the wood on each side of the blade and paring the ridge of wood between the scorings. The points continuously score on the stroke, their outside edge paring and the beveled front edge of each tooth in the cut, now in position, performing its chisel-like duty of crumbling up and dislodging the upper portion of the ridge of wood left between the cutters. The pieces are pocketed and carried out of the kerf by the throats or gullets at each thrust of the saw. A needle can be passed down between the teeth of a good crosscut saw, dividing the teeth so that one tooth is on one side, the next on the opposite side, and so on. A rip saw has its cutting edge chisel-shaped instead of pointed like the crosscut saw. The front is straight and the cutting edge strikes at right angles to the fibre of the wood, but severs it in one place only, the front of the tooth wedging out the piece of wood. With a view to demonstrating that the saw is based on scientific principles, an illustrated pamphlet by F. M. Bassler and copyrighted by Henry Disston & Sons, Inc., Philadelphia, Pa., has been prepared and given the title "Why a Saw Cuts." Though a handsaw consists of but a few parts, yet over eighty-two different operations are required to complete a Disston saw. A full understanding and appreciation of the work involved in its manufacture can be gained only by a personal trip through the works of the concern, where, step by step, in gradual development from crude, raw material, changed and refined in fiery furnaces, transformed under monster rolls, shaped by an army of expert mechanics, there finally emerges a beautifully finished and efficient article of utility. The principal operations which contribute to form the "king of tools" are explained at length in a booklet entitled "How a Disston Handsaw Is Made." Both of these booklets are well worth reading, and a copy will be sent free on request to the manufacturer.

The "Imperial" Floor Sander

There are numerous carpenters and contractors who feel the need of modern equipment to facilitate their work, but do not purchase the necessary apparatus because of the fact that prices, to them, are in many

Fig. 7—The "Imperial" Floor Sander

cases prohibitive. Up-to-date devices that are manufactured at a low cost and are accompanied by an efficiency guarantee are always welcomed by the trade, and we therefore take pleasure in illustrating in Fig. 7 the "Imperial" floor sander, recently marketed by the Imperial Pump & Tool Co., 2446 West Twelfth Street, Chicago, Ill. This equipment is one that is well within the means of the carpenter and contractor and will command attention because of its construction, light weight and simplicity of operation. The floor sander weighs but 14 lb. and is said to be heavy enough to do perfect work and light enough for one man to handle without the slightest trouble. It holds from six to twelve sheets of sandpaper and is shipped to the buyer loaded and ready for immediate use. To the top and center of the sander is a 5-ft. ash handle,

Why Have Heating Pipes in Your Partitions?

Now that you come to think of it, heating pipes are an awful hitch on construction work, aren't they?

But you don't *have* to hold up your mason and paper-hanger until the furnace man gets on the job. You don't *have* to take a chance of over-running the contract!

You can disregard the furnace proposition entirely until the house is completed. The Empire Pipeless Furnace does away with all partition work. May we tell you how it works?

57 W. Lake St., Chicago, Ill.

fastened by a knuckle joint, and heavy felt cushions are provided at each end to prevent marring baseboards when in operation. The sandpaper is securely held in place by means of $\frac{1}{4}$ -in. binding rods, which are drawn together with an iron buckle. This buckle holds the sandpaper, and as the paper wears out it is not necessary to loosen the binder, but by simply cutting off the worn sheet the next sheet is exposed and ready for use. The handle is so arranged that the operator can get a free sweep, the sander always remaining flat on the floor. The operator can stand in the center of the averaged-sized room and swing the sander from side to side without changing his position. He may first use a coarse sandpaper as he works across the grain of the wood and a finer sandpaper as he finishes the floor with the grain of wood. The device is said to be especially adapted for dancing floors, counter tops, bowling alleys, skating rinks, etc., and will be found convenient for removing varnish and for resurfacing and waxing floors. The company's catalog, which gives full particulars, together with the price, may be had on application to the given address.

Black Rock Wallboard

Supplementing the few comments which appeared in our last issue regarding the above-mentioned product, it may be of interest to builders to state that the wall board is made of four plies of material combined by a veneer process with a moisture-repelling black center.

Fig. 8—Showing Application of Black Rock Wallboard as an Interior Finish

This "stiff-as-lumber" wall board, as it is designated, has just been placed on the market and takes its name from its place of manufacture on the Niagara River. It is made by the Black Rock Wallboard Company, 1525 Ontario Place, Black Rock, N. Y., which claims that this name was chosen because "Black Rock" described in a way exactly what it aimed at in making a new wall board; that is, weight, strength and permanence. The claim is made that it will not warp, buckle, bulge or peel away from the nails; first because of its structure, second because of its weight and strength, and third because being strong and heavy carpenters find it easy to work and consequently are able to put it on the walls in first-class shape. Emphasis is laid upon the distinctive feature of the wall board, and that is its moisture-repelling black center. The company claims that the center being the heart of any board requires treatment just as much as the outside surface, and for the center it has selected certain well-known waterproofing agents which are black in character. This gives Black Rock Wallboard its distinctive center. The plan of the company is to have in practically every town one representative who alone will have the exclusive sales rights. As the company intends to adhere rigidly to this policy, it believes that these exclusive dealers will find the handling of its product an ever-growing proposition. In Fig. 8 is shown an interior where this wall board has been used as a finish.

A Revolution In Metal Lath

Here is the only metal lath with suction. Composite Metal Lath is a wire mesh covered with brick-clay under pressure and baked. It is made from the materials of which the largest and most wonderful structures are made—iron and brick. The picture above shows a section of Composite Metal Lath—Full Size View.

It makes adhesion positive—no falling of mortar from walls

and ceilings—no excess loss by “pushing through.” It assures a permanent bond.

Very flexible and easily handled. Can be erected with great rapidity and ease.

Composite Metal Lath is used with success for all outside or interior work. **No more cracking or falling stucco.** Send for circular and samples.

CONCRETE FOR PERMANENCE

Thousands of Jobs for Builders

In the past few years thousands of stucco homes have been built in Minneapolis, St. Paul, Kansas City, etc. All over the country the demand for good stucco is increasing. It is attractive, fire-resisting and requires no painting and very little upkeep. It is ideal for new homes and for remodeling old brick or wood homes, for garages, porches, dairies, etc.

A New Book that really helps

We have gathered a great deal of information about well-built Stucco into a "Guide to Good Stucco," a book containing detailed drawings of the different types of stucco construction, and a practical set of Stucco Specifications, to meet your needs. We will send you this book free. Also the Contractor's Atlas—a monthly digest of successful construction and sales ideas—and any other information that you ask for. Use the coupon below.

Name..... Address.....

New Sales Offices of the Kohler Co.

Rapid business growth and the widespread demand for Kohler Enameled Plumbing Ware have necessitated the opening of new sales offices at 404 Morris building, Philadelphia, Pa., with H. J. Hanna, Jr., as manager; at 1410 Candler Building, Atlanta, Ga., with R. G. Dobson as manager; at 3005 Jenkins Arcade Building, Pittsburgh, Pa., with Harry E. Clark as manager; at 725-726 Merchants National Bank Building, St. Paul, Minn., with Charles A. McKenzie as manager; at 1148-1152 David Whitney Building, Detroit, Mich., with Bart Downey as manager; and at 308 and 309 Pantages Building, Seattle, Wash., with W. B. Lambert as manager. The factory and general offices of the company are located at Kohler, Wis., with old branches and warehouses in the same cities as heretofore.

Wood-Mosaic Floors

A handsome brochure containing numerous halftone engravings of buildings in which its product has been used, has just been received from The Wood-Mosaic Co., 32 Hebard Street, Rochester, N. Y. It gives much valuable information regarding wood-mosaic floors and in addition are illustrated many patterns in natural wood colors. The statement is made that the company can reproduce almost any carpet design in a hardwood floor by the use of various woods the names of which are set forth. The cost of one of these floors, laid and finished, is said to be very near the price of a carpet, but ultimately, of course, much cheaper. Wood-Mosaic floors can be laid over an old floor with very little change in the floor level, doorsills, etc., by the use of wood 5/16 in. thick. If its agents are not near at hand, the company furnishes complete and accurate instructions for the laying of the floors so that the local carpenter need not go astray. A steel woven wood-mosaic floor is made to meet requirements of buildings of fire-

proof construction. The floor is made of blocks about 1 in. thick and 4 in. square. These blocks are grooved on all four sides and threaded on the floor onto strips or bands of steel, being so placed as to make the whole floor one solid, heavy mat. The floor is held in place by its own weight, and not being attached to the concrete, is at liberty to expand or contract. Compression strips close to the wall take up the expansion.

Edwards Metal Ceilings

An attractive catalog of 160 pages, bearing the above title, and containing a wide variety of patterns of Edwards' metal ceilings in "Stucco-Steel," "French Renaissance," "Italian Renaissance," "Colonial," "Gothic," "Rococo," "Greek" and "Modern" designs, has just been issued from the press. The illustrations are nearly full page size, thus allowing the architect or builder to readily obtain a clear idea of the details of each pattern. List prices, based on various sized rooms, are given, together with brief descriptive data of value to the builder and sheet metal contractor. There are also illustrations and prices of designs of side walls, cornices, moldings, borders, centers, etc. Among the closing pages are directions for measuring the amount of material required for rooms of any size, and there are also directions for applying it. With every pressed steel ceiling sold the company furnishes a drawing showing the arrangement of the metal, also a packing slip which contains an itemized list of all material, together with catalog number and size of each piece. Photographic views of interiors show some of the beautiful effects which may be obtained by the use of metal ceilings. The catalog is issued by the Edwards Manufacturing Company, 423-443 Eggleston Avenue, Cincinnati, Ohio, and the statement is made that any

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

LEAD PAINT

Dovetailed On

PURE white lead is metal lead in another form. Under a blow-pipe flame, it returns to the metallic state. A building painted with strictly pure white lead and pure linseed oil, like

Dutch Boy White Lead

and Dutch Boy linseed oil, is sheathed in a solid coating which, while not lead, is derived from this durable metal and has many of its characteristics.

This lead-like sheet, instead of being nailed on, might be said to be dovetailed fast, for it is held by thousands of tiny tentacles of the coating material itself. It is only as thin as paper but plenty thick to withstand the extreme changes of wet and dry weather and of burning heat and biting cold.

architectural effect can be obtained by the use of its ceilings, while any shade or color desired may be applied.

Corbin Rim Night Latches

A lock which will promise security against assault is not the least important feature in a house, and in an interesting publication known as "No. K-19" issued by P. & F. Corbin, New Britain, Conn., there is set forth a description of the ease with which the Corbin lock can be affixed to a door. The several steps are carefully illustrated, and the reader is told how well the lock is protected after being attached. It is stated that the lock can be used for either a right or left-hand door without change, two strikes being supplied so that the lock can be fitted to a door opening either in or out. It is said that these locks can be used on swinging doors and doors as thin as seven-eighths of an inch. The ball-bearing pin-tumbler cylinder used on the outside of the door is the same cylinder that is used on the highest grade of Corbin locks. It is said to have practically an unlimited number of changes of key, a key-way which will not admit a picking tool of any kind, ball bearings which permit the keys to pass in and out easily, and a master-keying system which is flexible, compact and trustworthy. In types not employing a pin-tumbler cylinder a secure locking mechanism is used. The tension of the spring is claimed to be sufficient to give the bolt a quick, lively action with a slight pressure on the knob, which is uniform throughout the entire movement. The pamphlet is illustrated with views of various portions of the locks, accompanied by a list of the supplied equipment and the price of a complete set per dozen. All locks are packed with directions for affixing.

Goodell-Pratt High Speed Hand Drill

One of the many new tools which the Goodell-Pratt Company, Greenfield, Mass., has recently added to its already extensive assortment is the High Speed Hand Drill No. 385, illustrated in a general view in Fig. 9. This new tool is one which cannot fail to be appreciated by wood finishers, floor layers and those who have occasion to drill a number of small holes in a short space of time. The gears, which are inclosed in an aluminum casing and packed in heavy grease, cause the spindle to make seven revolutions for each turn of the crank, the spindle running in ball bearings. The gears are lathe turned and machine cut. The chuck is of the three-jawed type and holds round shank drills, from 0 to 1/4 in. The handle is of polished hardwood with a large head.

Fig. 9—The Goodell-Pratt Hand Drill

Some Features of Asphalt Shingles

The utility and growing popularity of Asphalt Shingles among builders and property owners makes any instructive information relative thereto of more than usual interest at the present time. With a view to throwing light upon the merits of roof coverings of this nature, the Asphalt Publicity Bureau, 854 Marquette Building, Chicago, Ill., has recently issued a pamphlet entitled "Asphalt Shingles" which contains among the early pages some reference to the fact that "History Proves the Efficiency of Asphalt." The statement is made that waterproof materials, such as asphalt, pitch and bitumen, were used in prehistoric times in many ways. Their application to the royal mummies of Egypt and other ancient things show that the materials have endured in tests lasting thousands of years, as is proved by archaeologists. An asphalt shingle

(Continued on page 96)

Distinctly Different

Here is the reason. The "Trouble-Saver" Building Bracket has two legs instead of one. These mean stability. No shaky, unsafe, scaffolding with the "Trouble-Saver Building Brackets."

The legs brace against each other at the outer end and prevent any side motion. The bracket takes hold of the studding directly—no motion at the inner end.

"Trouble-Saver" Building Bracket

Up go "Trouble-Saver" Steel Building Brackets. You can erect as many in 5 minutes as you can wooden brackets in 5 hours. And it is just as easy to take them down.

Use "Trouble-Saver" Steel Building Brackets. It means a saving on time, material and labor; make your men feel perfectly safe, give them firm, solid and safe footing. Write for particulars.

PULLMAN MFG. COMPANY
8 Industrial St., ROCHESTER, N. Y.
Manufacturers of
Pullman All Steel Unit Sash Balances

is composed of a flexible body of wool felt made of very tough and strong long fibre. Hot asphalt is forced through every fibre and into every pore of this felt. It is then coated above and below with asphalt. On the upper surface is put a layer of crushed slate or rock, forced in under enormous pressure. A lower surface of crushed mica or other substance is put on to prevent sticking during transit, and this gradually wears loose after laying, allowing the shingles to bind closely together. The combination of these materials forms an elastic shingle which has enough pliability to give slightly under strain and which is yet stiff enough not to curl or blow up. It is stated that the slate or rock surfacing is permanent in color and that the shingle is an enduring guard against cracks or leaks. The original cost, it is claimed, compares very favorably with that of commonly used roofings and cheaper than slate or tile. The colorings of crushed rock include dark red, green, deep green, black, brown and gray. Asphalt Shingles are uniform in size, cleanly cut and measure about 8 in. wide by 12½ to 12¾ in. It is stated that they can be bent around corners and produce beautiful roofing effects. No changes are needed in order to use Asphalt Shingles in place of other materials. After the old roofing has been removed, they can be applied as quickly and easily as on a new house.

The Munger Three-Door Combination

out by the Chicago Millwork Supply Co., 1424 West Thirty-seventh Street, Chicago, Ill. The company calls attention to the fact that the door of a garage is a most important fixture and should be substantially constructed, easily operated and thief proof. The model shown in Fig. 10, is a combination set of three doors to fit a standard opening measuring 8 x 8 ft. The doors are 1½ in. thick, made of Oregon fir and weigh about 85 lb. each. They are 2 ft. 8 in. x 8 ft., and are furnished in two designs: the Stutz full paneled door or the Hudson, which has glazed double strength glass, as illustrated. Unlike the ordinary "barn-like" ceiling garage door, they are built as good as a house door and cost much less. The company guarantees perfect joints, good workmanship and strong construction. It is interesting to note that the owner may use the dead lock door for a private entrance, thereby saving a side door and frame. This is the season of the year when the carpenter and contractor are called upon to undertake considerable garage work, and the prices made will permit readers of THE BUILDING AGE to take advantage of the bargain offered on page 61 of the company's catalog, No. 321, as a means of building up much desirable business during the summer season.

Water Supply for Country Homes

One of the problems which confront the builder of a country home is the provision for an adequate supply of water in all parts of the house when no public main is accessible to be tapped. A fifty-page booklet, entitled,

Stanley Adjustable Spoke Shaves

These new and improved Spoke Shaves have a Lever Cap fastening the cutter in such a manner as to bring an even pressure on the cutting edge.

The important feature is that the cutter can be quickly adjusted both endwise and sidewise by means of the adjusting screws which engage the slots near the end.

The cutters are made from a high grade of steel, well tempered and sharpened ready for use.

The handles are japanned and through each a hole is made to enable the owner to hang the tool up out of the way.

Made in two styles—one with raised and the other with straight handles.

If your dealer cannot supply you write us direct.

STANLEY RULE & LEVEL CO.
NEW BRITAIN, CONN. U.S.A.

"Standard Pumping Units," containing illustrated descriptions, prices, directions for installation, etc., of various plants, severally applicable to deep or shallow wells, as may be necessary, is being sent out by the Standard Pump and Engine Co., Akron, Ohio. Hand power, electricity or engine-driven systems may be used, different sizes being suitable to requirements ranging all the way from those of two or three persons up to those of a large plant. A few pages toward the end of the booklet are devoted to tables of comparative equivalents of liquid weights and measures, open weir measurement, pipe friction, etc., likely to prove of interest.

Sheet Metal for Interior Decoration

An interesting example of the use of sheet metal for interior decoration is found in the case of the Criminal Court Building on Schermerhorn Street, Brooklyn, N. Y., and which was formerly the Germania Club. In 1890 a sheet-metal ceiling was installed on the main floor of the club by Northrup, Coburn & Dodge Company, 43 Cherry Street, New York, and when the building was made over into a court house with numerous partitions it was necessary to remove the old sheet-metal ceiling and install new work in the various rooms. When the old ceiling was removed it was found to be in excellent condition after twenty-six years of service

Fig. 11—An Excellent Example of Sheet Metal as Used for Interior Decoration

and the company attributed much of the durability of it to the original priming paint which was used. In Fig. 11 of the illustrations we show a portion of the new ceiling of one of the rooms in the court house, the architect, Frank H. Quimby, 99 Nassau Street, New York City, stating that the work is one of the most satisfactory jobs of ceilings he has ever seen.

The Slate Roofer

A little work which cannot fail to prove both timely and interesting to architects, builders, roofers, quarrymen and dealers is the ninety-six-page publication, describing the kinds of slate in the United States, the buildings for which they are particularly adapted, the comparative sizes of slate, rules for measuring slate roofs, together with directions for laying slate and felt, which is being sent out by the Auld & Conger Company, Department A, Cleveland, Ohio. In addition there are designs for ornamental work, a statement as to the nails required for a "square" of roofing, rules and information which will be appreciated by those just entering the roofing business, etc. A series of tables, occupying nearly one-half the book, gives the number of pieces of slate in any number of feet or squares and is intended more particularly for roofers

and dealers in slate, as slate is always bought and sold by the "square" or square foot. Some comments in regard to setting slate blackboards are among the other interesting features of this little work which has been compiled by D. Auld, Jr. The price is 50 cents.

American Saw Mill Machinery Company Removes Sales Department to New York City

Believing that it will be in better touch with the markets of the world both in selling and purchasing, the American Saw Mill Machinery Company has removed its Sales and Purchasing Departments from Hackettstown, N. J., to 50 Church Street, New York City. The company has had an office at this address for a number of years, handling its eastern and foreign business, and now additional space has been secured and a fine suite of offices especially arranged for promptly meeting the demands of its trade. Customers visiting New York City are cordially invited by the company to make these offices their headquarters while in the city. The location is in the Hudson Terminal Building reached by all Hudson River tubes and convenient to elevated railways and subways.

The Latest Pullman Sash Construction

An improved form of sash construction embodying features which cannot fail to interest architects and builders generally has just been developed by the Pullman Mfg. Company, Rochester, N. Y., and an illustration of it is presented in Fig. 12. The idea is to secure a

Fig. 12—Showing Details of Latest Pullman Sash Construction

maximum of glass area in a given opening and the plan evolved requires only 18 in. of wood for a group of three double-hung windows, all the rest being glass. This also includes the stiles of the sash. The frame is exceedingly simple, being constructed of 2 x 4's grooved for the parting strip. The inside and outside trim is also of the simplest possible construction and stops are entirely eliminated. The sash is controlled with the Pullman "Unit" top balancers. The illustration represents a partial elevation and horizontal cross-section of the improved construction.

Slate as a Roofing Material

There are many facts which should be familiar to all architects, contractors and owners of buildings regarding the coverings used for structures of all kinds, and one of the best known perhaps is slate—a natural product which embodies no mixture of any kind but is simply taken from its bed like granite, marble or coal. In addition, it has the peculiar characteristic of being split into thin sheets and then with dressed edges made ready for roofing purposes. As is well known, slate is exceedingly durable and in many instances where slate has been used upon a roof for more than one hundred years is still in good condition. The Genuine Bangor Roofing Slate has been produced for more than sixty

(Continued on page 102)

Summer Is Building Time

Soon there will be a demand in all localities for men to build new barns.

This call is welcomed by the contractor who uses **PORTER SERVICE**, since he knows he can build the new barn in double-quick time and guarantee a thoroughly modern and workmanlike job.

Consider what it means to receive authentic and practical data covering the construction, arrangement, ventilation, etc., of each individual barn. That's what **PORTER SERVICE** renders—and it's **FREE**.

Wood staining recipes.

Putty, cements and glues for wood.

Number of nails to pound.

How to figure board measure, shingles,
paint, brickwork and stonework.

And 50 other subjects.

Send for Book No. 5

MILLERS FALLS CO.

105 River St., Millers Falls, Mass.

years, and the statement is made that the first slate manufactured in the oldest quarry is in good condition, having covered buildings for the period named. Experience has shown that slate properly applied to a roof is economical in the end and controverts the many statements which have been made in published articles relative to the excessive cost of slate roofs. A roof covered with slate is fire-resisting, is attractive in appearance and seldom calls for repairs. Bearing upon the subject is the literature which is being sent out by the East Bangor Consolidated Slate Co., East Bangor, Pa.

Standardizing Hollow Steel Doors

There are many features in a hollow steel door which make it superior to doors constructed of other materials, and in the past it has been necessary for them to be made to order, rendering their cost such as to prevent their being used in any but the more expensive buildings. This high cost has been such as to cause the Solar Metal Products Co., Columbus, Ohio, to make an effort to reduce it and to this end set about an analysis of several thousand jobs that had gone through its factory prior to 1915. As a result it discovered that most of the orders might have been standardized, thus eliminating the necessity of special attention and cost in each job for estimating, designing, dies, machinery, maintenance of drafting departments, etc., which would bring the cost low enough to justify their use in moderate priced buildings; furthermore making a better product possible. As stated in an attractive brochure entitled "A New Deal in Hollow Steel Doors," the company can now supply steel doors and trim at short notice, giving all necessary quotations on request. The doors have service and finish guaranteed. Details and specifications of Solar installations are compiled in convenient form in the "Architects' Solar Handbook," issued by the company.

Wire Chairs and Settees

Among the leading products of the Buffalo Wire Works Company, 446 Terrace, Buffalo, N. Y., is a line of wire chairs and settees which are of special interest

Fig. 13—A Wire Settee for the Lawn

just as the summer season is opening and when furniture of this kind is being placed on the lawns. The goods are constructed entirely of wrought iron and wire, the settees being well painted, after which they are baked, this giving a finish which, it is claimed, will not rub off. At a small additional expense the company will galvanize them if so desired, thus making them rust-proof. In Fig. 13 of the illustrations we show a settee of this character of a size capable of seating two people. The length of the seat is 45 in. and the weight is 40 lb. The claim is made that these settees are much lighter, stronger, and more durable and ornamental than those made of wood.

Asphalt Shingles in Roll Roofing Form

One of the latest developments in the prepared roofing line, and which cannot fail to prove interesting to architects and builders throughout the country, is a roofing made up of a roll, 32 in. wide, of asphalt shingles. The advantages of such a roofing cannot fail to be appreci-

(Continued on page 104)

AN IMPROVED CONVERTIBLE LEVEL

It takes but a few moments to convert the instrument for use as a level, from its position for taking vertical sights without detaching the axis from the telescope. This is on account of the one-piece phosphor bronze axis.

TRADE NOTES

The Blue Valley Slate Manufacturing Company, with offices in the Behler Building, Slatington, Pa., has issued some interesting literature relating to roofing slate, blackboards, etc., copies of which can be obtained by any reader of the paper upon application to the address given. One of the folders sent out gives the size of slabs from 1 sq. ft. upward and intended for switchboards, etc. There are also prices of slate for electrical uses, sand finished on one face and edges. Reference is also made to slate slabs for structural, sanitary and other purposes.

An attractive pamphlet of sixteen pages setting forth the merits of Roberds' "Ideal" wall board is being sent out by the Roberds Manufacturing Company, Marion, Ind. In addition to much interesting information relative to this product, there are numerous halftone engravings representing interiors finished with the wall board in question. The company refers to its product as "the modern sanitary, fire-resisting, waterproof interior wall board."

A single-register furnace which embodies features of construction that are likely to appeal to architects and builders because of its low initial cost, ease of installation and all-round efficiency as a heater for a house of ordinary size is the Stewart, made by Fuller & Warren, Jackson Street, Troy, N. Y., and 260 Water Street, New York City. This construction is said to be especially desirable for heating cottages, stores, churches, residences, etc.

The Oak Flooring Service Bureau, 1349 Conway Building, Chicago, Ill., has been distributing among those likely to be interested an attractive folder relating to oak flooring. Reference is made to the beauty of these floors as well as to their wearing qualities, also to the fact that an oak floor properly laid greatly increases the renting and selling value of a dwelling.

Information of interest to the builder whose business warrants the expenditure for a motor truck is contained in the April issue of *Traffic News*, the house organ of the Federal Motor Truck Co., Detroit, Mich. It is stated that many Federal trucks are in use in the United States Army, a Model K, No. 2780 having recently been attached to the Post Exchange, at Fort Oglethorpe.

Lobb, Parry & Co., of which Ernest Lobb is manager, National Building, Danielsville, Pa., are directing attention to their line of roofing slate for blackboards and structural purposes. A great variety of slate products is produced, and builders and roofers can obtain copies of interesting circulars on application.

An illustrated folder sent out by the Yaeger Machine Company, 216 West Rich Street, Columbus, Ohio, presents nine reasons why the building-contractor should decide on using the "Yaeger" spouting plant. The plant, it may be stated, consists of the Yaeger "Big-an'-Little" mixer with loaded and auxiliary hoist of 5 hp. engine and mixer drum of 5 to 6 cu. ft. capacity.

The books themselves, not what we say, must convince you that you need them, so send the coupon to-day—now—and the entire eleven volumes will come to you at once, express prepaid. If, after a full week's trial, you decide to keep them, you can buy them at half the regular price and on the easiest of easy payment plans.

New 1916 Edition Cyclopaedia of Architecture, Carpentry and Building

consists of ten large volumes, handsomely bound in half morocco, gold stamped, containing 4,760 7 x 10-inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross indexed for quick, easy reference.

PARTIAL TABLE OF CONTENTS

Mechanical, Freehand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

Plan Book and Consulting Service FREE

We give free to every purchaser of our Cyclopaedia of Architecture, Carpentry and Building, a copy of "Modern American Homes," a complete and up-to-date plan book. Contains plans and specifications for 168 structures, including excellent exterior and interior views, detailed estimates, etc. Designed by leading architects, it covers city, suburban, and country homes; bungalows; summer cottages; tent houses and camps; apartment houses; garages, and public buildings. 224 pages, 9 1/2 x 12 1/2 inches, and 426 illustrations. Printed on enameled paper and substantially bound. With this plan book in your shop you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect—you can offer him his choice of practically every type of home. This saving of the usual architect's fee should get you the business.

In addition we give free with each set a year's consulting membership in the American Technical Society. Through this service you have the assistance of a staff of architectural and building experts. These men are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

Send for this great combination today!

We will send the complete eleven volumes to your home for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet your expectations they may be returned at our expense. If you keep them send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80—regular price \$50.00—has been paid. Remember—the consulting membership and plan book are included absolutely free.

Can you afford to let \$2.00 a month—60c a week—stand between you and success? The consulting membership alone is worth many times the first cost of the books. Fill in and mail the coupon—NOW!

OUR NEW WIRE WORK AND ARTISTIC METAL WORK DEPARTMENT

The great demand for "Buffalo" Wire Cloth, Wire Work and Artistic Metal Work has compelled us to move our Wire Work Department to larger quarters. Our Wire Work Department will hereafter be located at corner of Terrace and Genesee Sts., where we have a floor space of 25,000 sq. ft. available for manufacturing our large variety of wire work, artistic metal work, etc.

It also gives us more available room for increasing machinery, etc., in our weaving department, which has also been constantly growing in demand.

We are pleased to announce that since opening our Philadelphia Branch Office and warehouse last September we have also increased our quarters, taking in three additional floors at No. 9 South 7th St., adjoining our present Branch at No. 11 South 7th St., giving us an additional 10,000 sq. ft. of floor space on which to carry a still larger stock of "Buffalo" Wire Products for our customers and patrons in Philadelphia and surrounding territory.

We feel that with additional floor space and manufacturing facilities we will be in better position to render to our customers such service as we always endeavor to render to them.

Remember! "BUFFALO" QUALITY, SERVICE AND SATISFACTION are the three features upon which all "Buffalo" Wire Products are manufactured and sold and to which we attribute our large success and constantly increasing demand for our products.

Are you acquainted with our line? If not, send for a copy of our new No. 8-H catalog which will be sent to you gratis.

Don't Pull the Cat Across the Carpet By the Tail

"I mind, one winter's night, the old woman says, 'Tim,' says she, 'be sure to put the old cat out before you come to bed.' Old Tab was a layin' on the carpet in front o' me an' I reached down an' ketched a-holt of her by the tail, bein' about the most convenient part o' her to git a-holt of, and started to take her out to th' back door, but she stuck all o' her claws into th' carpet and squalled and spit, an' the ol' woman says, says she, 'Tim, you brute, what you doin' to that poor dumb beast,' an' finally I jest had to take the cat by the neck an' pick her up to get her out a-tall.

"An' I says to myself, 'Tim,' says I, 'Let that be a lesson to you, go at things right an' don't never try to pull the cat across the carpet by the tail.'

"An' it was jest the same way with a contractor I worked for onct! He went an' bought a lot o' things that was said to be wheelbarrows, jest becuz they wuz a little cheaper'n STERLINGS, an' befor' he'd had 'em a week they wuz screechin' an' squallin' an' breakin' down an' wearin' out the men that wuz a pushin' 'em an' he never did have no luck 'till he sold 'em to a junk man an' got a lot of STERLINGS.

"An' that's jest the way with everything. It's a whole lot better an' cheaper in the long run to do things right while yer a doin'."

TIM TRUNDLE

Sterling

BARROWS are right. Oil-impregnated fiber bushings for wheel bearings make

STERLING BARROWS self-lubricating. No squeaking; no oiling nuisance to gather dust, sand and dirt and grind out the bearings. STERLING BARROWS run easier, last longer, carry heavier loads, yet they're not expensive after all.

Blystone Batch Mixer

For Plaster-Concrete-Mortar

A saving of \$25.00 per day was made in mixing hardwall plaster for the big Machinery Palace for the Panama Pacific Exposition.

The Cement Tile & Block Mfg. Co., of Osgood, Ohio, paid for their Blystone in three months work in their block plant.

One man slaked lime and made mortar for ten masons and had time to spare for other work on a job recently done by G. Ed Berry, of Harrisburg, Ill. Mr. Berry also says he got 10% more mortar per barrel of lime.

H. A. Farmer, St. Petersburg, Fla., recently wrote us as follows: "I am so well pleased with mixer. I want another just like it. Ship me another one as soon as possible."

you
going
to do?

IDEAL
CONSTANT SERVICE
POWER

Are you going to be content with your last year's equipment?

—or are you going to forge ahead and adopt for your 1916 work Constant Service Equipment?

Picture for a moment an engine with the latest improvements—

Simple in construction and requiring no skilled labor to operate—

With power to more than handle the work given it—

With strength to withstand the most exacting service—

With a pulsing, live action that insures "Constant Service" for your equipment—

You can almost see the dollars of extra profit rolling in when you equip with—

Ideal Engines—the engine of "Constant Service"—the solution to your power troubles—the builder of profits.

We offer you in **Ideal Engines** that which every contractor wants—power and plenty of it, when it's needed.

Why not equip with **Ideal Power** now?

Our special booklet No. 516 will interest you.

BIG PROFITS

Are Assured by the
"Ropeless," "Sheaveless"
Gear-Lifted Loader on the

SMITH MIXERETTE

LOAD one batch into the wide, "ground level" skip while another is being thoroughly mixed in the drum.

INSERT the long, steep-angled discharge spout. It will discharge the entire batch in **nine** seconds.

THROW in the jaw clutch engaging the train of **steel** gears. These lift the skip to an almost vertical discharging position.

LONG, steep sides and wide mouth of skip insure a fast, clean discharge into drum without spilling.

DRUM holds 3 cu. ft. of mixed concrete—N. A. M. M. rating—and will turn out 5 cu. yds. per hour.

THIS all-steel mixer is light, portable and easily handled. Will produce **BIG PROFITS** on every class of concrete work.

SEND for new folder, No. 115-H, describing all combinations of the Smith Mixerette. Fill in your Name and Address.

"The Standard"

Low-Charging Concrete Mixer

illustrated herewith is the same style machine as the two shown in the photograph reproduced in our advertisement which appeared on page 110 of the May issue of The Building Age. They are built in ten sizes, with capacities ranging from 3 to 40 cu. ft. of unmixed materials per batch. It will be to your advantage to get our Catalog No. 48-6, illustrating and thoroughly describing this and other machines. Low-Charging will save you one-third.

"The Standard" Equipment

HOISTS—Single and double drum, reversing with gasoline power, are desirable on account of low first cost and small operating expense, and the light weight, enabling the outfits to be placed in the most convenient position. The outfits illustrated are especially adapted

for operating double platform contractors' elevators and direct hoisting with single line.

PUMPS—with gasoline engines for power, give excellent results and are a necessary part of the contractors' equipment. Outfit illustrated is recommended for pumping trenches, cellars, etc. It can be furnished mounted either on skids or trucks.

WHEELBARROWS AND CARTS—Our wheelbarrows and carts are extra well made and balanced, consequently easy to handle. Built in all sizes. Get our Complete Equipment Catalog No. 48-6E.

The "S.S.S." Low-Charging Concrete Mixer

is our new low priced mixer built in 4 sizes of 3, 6, 9 and 11 cu. ft. per batch, and is adapted for the builder of small foundations, sidewalks, curbs and gutters, small bridges, culverts, etc., where it is necessary to move the outfit frequently. Write for our new 16-page catalog No. 48-6S on this mixer. It contains some valuable information.

A Little Fellow for Big Jobs as Well as Small Ones

If you want a concrete mixer that you can easily transport from job to job—any job—The Archer is your machine.

It's a small mixer, but as sturdy and adaptable as they make 'em.

One man and an Archer can turn out at least 50 cubic yards of concrete per day; perfect batches, every one of them! He can wheel it to the work all by himself.

May we send description and prices?

The Archer Iron Works, 2440 W. 34th Place, Chicago, Ill.
Established 1891

It is a GRAND Mortar Mixer

For you contractors and builders, with mortar to mix and temper, here is the Grand. It is just the Mixer you want. Ready to do a good job at any time or any place. You can take it from one job to another as easily and quickly as you can take a wheel-barrow.

Put the twenty-six paddles to work in the Grand and you obtain enough mortar to supply 40 or 50 men. The 4 H. P. Engine operates the Grand to maximum capacity.

Ruggedly built for long and hard service; it is ready to help you get better mortar in quick time. Send for catalog.

EXPANDED CUP
**SYKES SELF FURRING
METAL LATH**

Saves 5 to 10 cts. a sq. yd.

For Interior Work as well as for Stucco Work Sykes Expanded Cup Metal Lath is best, not only because it saves the cost of furring strips but also because of its *weight*, its perfect *key*—the rigidity and durability of the wall it assures.

SYKES EXPANDED CUP
METAL LATH
EST. 1877 SELF - FURRING

This Metal Lath is heavier than others, therefore more rigid, more durable. Its peculiar formation allows it to reinforce the wall more surely—for this lath is imbedded in the mortar $\frac{1}{4}$ inch. Note this cut:

Sykes Expanded Cup Metal Lath

Now look at this cut

Ordinary Metal Lath

The point of weakness is over the stud where the mortar gets no "grip." Less mortar is required when you use Sykes, because—all grounds being measured from face of stud not from face of lath—the key mortar in Sykes Lath is largely in the wall.

For an Honest, Durable Job Use the Lath That Makes a Real Backbone of Lasting Strength—Sykes Expanded Cup Metal Lath.

Approved by U. S. Government for Post Office Work. Indorsed by Architects and Contractors.

Free Booklet—Metal Lath Specifications—and free sample of Sykes Metal Lath on request

**Sykes Metal Lath and
Roofing Co.**

494 River Road, Warren, Ohio

Waterproof Moistureproof Stucco

THERE is only one way by which you can be absolutely assured that rain or moisture will not percolate through cracks in the stucco, make the stucco fall off, penetrate the wall and ruin the interior, as occurs in cement, lime and other exterior coatings, and that is by using the one waterproof, moistureproof stucco.

KELLASTONE

IMPERISHABLE STUCCO

In the first place, Kellastone does not crack or shrink from window and door casings, and is not subject to the great expansion and contraction which causes other stuccos to crack, allowing water to enter. Add to this its remarkable impermeability to water and moisture, and resistance to heat and cold, and you have the one practically indestructible seal, the one perfect exterior coating for any home or building. Kellastone will "give" to stresses and to the normal settling of walls. It adheres with extraordinary tenacity to wood, brick, tile or stone. It is proof against the results of extreme changes in temperature, and is fireproof. It is the only dependable stucco. Used by the U. S. Gov't., railroads, hospitals and homes everywhere, and for renovating and over-coating old buildings.

Kellastone Composition Flooring solves the flooring question, for schools, hospitals, factories and homes, being superior to concrete, tile, wood or rubber-tile, because it has no seams, joints or cracks, deadens sound and is practically indestructible.

Send for the illustrated proven facts today.

Berger's Pressed Steel Cores Reduce Dead Floor Load

BERGER'S Pressed Steel Cores, for both light and heavy long-span construction, are extensively and effectively used for concrete floors. They are designed to give the greatest strength and displacement for the least amount of weight and cost, at the same time making a great saving in concrete reinforcing steel, centering and labor—also materially reducing the dead floor load.

Made from sheet metal, formed from one piece and corrugated, making them very rigid and stiff. We make both permanent and removable cores in several sizes, depths and gauges. They can be used in any type of steel frame or reinforced-concrete construction.

*Write for full particulars

CON-SER-TEX CANVAS ROOFING

It Solves All Roofing Problems

Investigate the merits of this roofing material. Its claims for your consideration are based on the following facts:

Costs very little. Is easy and inexpensive to lay. Makes a neat, smooth, durable surface. Will not leak, rot, stretch or shrink.

CON-SER-TEX is a specially woven canvas roofing which is chemically treated to preserve the fibre from mildew and the detrimental action of the oil in paint. It is water-proof, rot-proof and wear-proof. When properly laid, it will last as long as the house itself.

It is furnished in such widths and weights as are best suited for various classes of work, thus practically all waste is eliminated.

A postal will bring our new book, "Roofing Facts and Figures." Send for it now. It's interesting and will help you save money.

(My commission expires March 30, 1918.)

THAT WOOD CORE

is responsible for the many desirable qualities of

Compo-Board
TRADE MARK

Trade Mark Reg. No. 94745

Consider first, of course, its chief use as a wall lining, and why, because of its wood core, it is *better* in every way than lath and plaster, stronger, more durable and sanitary.

Because it has 101 other uses, such as:

- lining summer garages and outdoor sheds for warmth.
- lining summer cottages (helps keep them cool).
- quick repair partitions.
- enclosing rooms in attic or cellar.
- building dust proof closets or cabinets.
- panels in wainscoting or beamed ceilings.
- shelves, drawer bottoms, cabinet backs, etc.

Sold by dealers everywhere. Write for free sample and interesting booklet.

The Compo-Board Company
5778 Lyndale Ave. No., Minneapolis, Minn.

Stucco and Metal Lath Stand the Wear

Stucco went into the walls and posts of the porch on this frame house because the builder knew that there was where the wear and tear would be. To make the permanence of the job *certain*, the stucco was laid on a base of

Kno-Fur Expanded
Metal
Lath
Used Without
Furring and Sheathing

"Kno-Fur" will save you time, labor and material as a base for stucco work because it is made with a "U" shaped rib that makes the fabric rigid as soon as the plaster is applied—no furring strips necessary. It is made with the "Kno-Burn" mesh with the bull-dog grip.

Send for booklet No. 43 with particulars on the whole North Western line

BAYONNE

Superior to Copper Roofing

The inferiority of Copper roofing extends further than its unreasonable cost at the present time—although now this is one of the gravest objections to its adoption.

Copper, as well as other metal roofings, is subject to expansion and contraction with changing temperature—and the natural consequences are bulging, warping and cracking.

BAYONNE

is not in the least affected by cold or heat. It is very simple and surprisingly economical in laying; laid on the dry boards, tacked only on the edges; and only one coat of paint is required for ordinary purposes. When once laid, BAYONNE positively stays flat.

Furthermore, it does not blister, crumble and corrode like other prepared cloths and tar roofings—and it never leaks. Not a drop of water, no moisture, can possibly penetrate it. It can be, therefore, kept ever clean and neat by simply putting the hose on it.

Cellular Lath Company:

I used your Keezon Cellular Lath on the new Institutional Building of the Kings-highway Presbyterian Church, and have found it so satisfactory that I take great pleasure in commending it to others.

GEORGE F. BERGFELD,
President Bergfeld Realty Company.

Get the Facts About Keezon Cellular Lath

Write us now for full particulars regarding the lath that is revolutionizing the lath industry. The lath that saves 30% in time, labor and material. The lath that assures a job unequaled from a quality standpoint.

Keezon Lath is fire-resisting and can be specified in slow burning construction. Keezon Lath can't rust. It is unequaled for stucco work. It can be applied to flat surfaces without furring. It can't warp, buckle, expand or contract.

Keezon cellular construction forms a key to which plaster clings with greater tenacity than it will to any other known form of construction. In a test made to demonstrate the holding strength of the Keezon Key, water to the depth of two inches was poured on top of a Keezon ceiling and allowed to remain for twenty-four hours. At the end of that time most of the water had soaked through the plaster without causing the slightest loosening or sagging.

Berger's "Classik" Steel Ceilings in a Haberdashery Store.

Reasons Why You Should Install

*"BERGER'S
Classik"
STEEL CEILINGS*

Beauty—They give an attractive, decorative, embossed finish that compares favorably with expensively moulded plaster. Hundreds of beautiful designs that harmonize with any type of architecture.

Safety—They are fire-retardant and, unlike plaster ceilings, cannot crack, chip or fall down.

Adaptability—They are suitable for any interior—store, home, church, theatre, garage, office, public building, etc.

Ease of Application—They are quickly and easily erected, due to our improved bead and button construction, which eliminates tamp-

ing and calking. This saves you 25% to 40% on every job.

Perfect Construction—The dies, from which these ceilings are made, are reproductions of skilfully clay-moulded originals, while the stamping done on our special machines brings out the beauty of design sharp, clear and true. Each unit is rigidly inspected and guaranteed against defects.

Reasonable in Cost—Their first cost, which is moderate, is the only one, as they last as long as the building itself.

Profitable—Each installation means a good profit for you, and at the same time is a perpetual recommendation for future business and profits.

With all these good points in mind, write for full particulars and copy of "Classik" Catalog D. B., showing hundreds of designs and many installations. Just send the coupon.

THE GARDEN AND ITS FURNITURE

WHEN is a mere plot of ground transformed into a charming garden, a restful retreat? When the garden is properly planned and those plans properly carried out; when it reflects the individuality of the owner; when the lawns, beds, hedges, pools and statuary, the garden benches, sun dials, bird houses and fences all form one harmonious unit.

The June number of *House & Garden* treats of garden furnishing in a lucid, entertaining way—it gives plans for Italian, English or Japanese gardens; Japanese gardens in America; window boxes and color schemes for their contents; flowers for the seaside garden; the fun of raising pigeons; col-lies; how to balance an aquarium; in short—31 topics of interest, with 170 illustrations.

House & Garden

with which is incorporated American Homes and Gardens, was recently purchased by Mr. Condé Nast, who publishes Vogue and Vanity Fair. Already, House & Garden is known as a superior monthly magazine of town and country life, of interior decoration and furnishing, which leads in its special field as Vogue and Vanity Fair are acknowledged to lead in their respective fields.

\$1 May Show You

how to save \$100 or even \$1,000 or over. You could easily waste that much on furnishings that do not harmonize or gardening that does not please, or in building that is not practical. *House & Garden* removes the possibility of error in this regard.

A Special Offer

The subscription price is \$3 a year; single copies at the newsstands are 25 cents. But if you will fill in and send the coupon, with \$1, we will mail you the six forthcoming numbers.
"All Indoors and Out"

House & Garden, 440 Fourth Avenue, New York City

Building Age Colored Perspectives

Do You Want a Set of 27?

WE have a limited number of sets of 27 each of the beautiful three and four-color perspectives, same as those used in various issues of BUILDING AGE. There has never been an opportunity for getting such a varied collection of beautiful perspectives, and as we have no remaining copies of most of the issues of BUILDING AGE in which these appeared, and as the expense of reprinting them in color—unless in very large quantities—would be prohibitive, it is probably the last opportunity of securing a set.

We have constant inquiries from subscribers for these prints separate from those bound in the magazine. Many frame them; others use them as suggestions. While they last we will send a set for one new subscription, or for renewal of your subscription for one year from date to which it is now paid; two dollars to accompany order, or enclose a dollar bill at our risk for the set.

Address orders to—

Manager, BUILDING AGE

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

National Sheet Metal Roofing Co., 339-345 Grand Street

Don't Miss This Opportunity

We Want One Representative in Every Community to demonstrate, Take Orders for and Apply Our EDWARDS METAL SPANISH TILE ROOFING on a Liberal Commission.

Here is a chance to build up an independent, profitable business for yourself right at home. Many are now devoting their entire time to selling our metal roofing. Others have made big profits simply devoting part of their time to selling and laying our Metal Spanish Tile.

Edwards Metal Spanish Tile

Is being advertised in the leading magazines and is now known to thousands of home builders and owners everywhere. Wherever it has been used it has made a decided "hit" because it shows off to good advantage on the roof and has numerous points of superiority over any other style of roofing.

Architects are specifying Edwards Metal Spanish Tile, for they know it will do away with roofing "Troubles." Builders like it because of the finished appearance it gives any house on which it is used.

Our Metal Tile are stamped out of the highest quality Worcester terne plate in exact imitation of the most expensive Terra Cotta Spanish Tile. They come either "dip" painted or heavily galvanized size 10 x 14 inches. Our patented interlocking side lock makes it possible to make a perfectly moisture-proof roof without soldering. Edwards Metal Spanish Tile afford the fireproof advantages of Terra Cotta Tile, but are much lighter in weight, cost but a trifle more than ordinary roofing and will last a lifetime.

WRITE US TODAY ABOUT YOUR TERRITORY. Our business is growing so rapidly that it is necessary to have an agent in every community. The territory is going fast. One day's delay may mean that some one else will be given your territory. DON'T DELAY. WRITE TO-DAY FOR OUR SPECIAL AGENTS' PROPOSITION.

Residence of A. W. MacCallum, Architect, Merchantville, N. J. Illustrating the versatile effects obtainable with Ambler Asbestos Shingles Century Brand and Ambler Asbestos Sheathing

What roof will *you* recommend?

The fires of Augusta, Nashville and Paris have burned out and the accusing fingers of fire-marshals and level-headed citizens are pointed at combustible roofing. You will specify a fire-proof roof, of course, but why not give your customers

*The Roof That Is as Permanent
as the Foundation*

The one roof that is at once beautiful in appearance, fireproof, waterproof, storm-proof — which never needs repairs.

Made of cement and asbestos, Ambler Asbestos Shingles Century Brand *cannot* burn. The fibres of the asbestos twine and intertwine through the cement, reinforcing them far more thoroughly than steel rods reinforce a wall. They cannot break.

Every Ambler Asbestos Shingle

Century Brand is subjected to a compression of 700 tons to the square foot; there are no air holes through which water may filter.

Perfectly impervious to water as a unit, our system of application locks a roof of Ambler Asbestos Shingles Century Brand into one waterproof, storm-proof, fireproof whole.

An Ambler Asbestos Shingle Century Brand roof, when properly applied, is cheapest in the end.

FLEX-A-TILE ROLL SHINGLE

(PATENTED)

WE had in mind, when we designed this new Flex-A-Tile Roll Shingle, the growing demand for asphalt shingle roofs that would cost little to lay. How nicely we have accomplished this economy is surprising—this full-size, 32-inch wide roll of asphalt shingles takes no more labor to apply than ordinary roll roofing.

IT is a splendid shingle roofing, too—satisfying perfectly the requirements of those who heretofore would never roof with commonplace roll roofings.

OF course, the illustration above cannot begin to give a realistic idea of the true beauty of the shingles—nor can it show the distinctive way each single shingle stands out without the aid of paint or any imitation process to produce the genuine appearance of individual asphalt shingles. But, let us send direct to you a sample of this Flex-A-Tile Roll Shingle. Hold it in your hand. Feel its weight. Test it any way you will.

Just Write Today

Say that you are interested in the new Flex-A-Tile Roll Roofing and mention what your business is. We will forward liberal samples, prices, and any other information you may wish:

Sales Office and Parquetry Factory, Rochester, N. Y.

CONCRETE and stucco can be made beautiful with Bay State Brick and Cement Coating—can be given a rich, artistic finish in harmony with the architect's ideas. This overcomes the dreary blue-gray and makes an attractive white or tinted wall.

Bay State Brick and Cement Coating

has another great advantage—it's absolutely waterproof. It fills the porous cement and prevents water seeping through. As an interior finish, nothing compares with Bay State. It resists fire, steam, acid and water—reflects the light and will not peel or dust off.

Builders and architects everywhere endorse it. We'll send A SAMPLE CAN, FREE if you'll try it. When you write, say what tint and ask for Booklet 19.

"I can recommend it"

"I was a Builder 3000 years ago and My efforts are still standing"

—and the same principles in use when the pyramids were built, used in building construction ever since, and *today* acknowledged the most efficient, are combined in that modern, dependable background for stucco, cement or plaster finished houses

Bishopric Board will not corrode—it cannot break away or sag. It contains nothing but creosoted lath, asphalt-mastic, and heavy fibre board, that will outlast any materials known, that is proof against moisture, vermin, heat and cold, and that holds the stucco in its dovetailed grip so it can't crack, loosen or let go.

Bishopric Board costs less than other backgrounds and saves at least 25% in material and labor.

Our book "Built on the Wisdom of Ages"

gives facts and figures to prove our claims. It also illustrates homes, apartments, factories and public buildings constructed with Bishopric Board, and gives letters from architects, builders and users, also some interesting results of scientific tests.

Write today for samples and this book—all free.

Can You Imagine This?

70% of all the floor scraping done in Chicago last year was done with Triple "A" SPRING-DRIVEN Floor-smoothers.

Why?

In view of all other floor scrapers on the market there is bound to be a good reason for using this particular kind of a machine on so large a percentage of the work—more than double the work of all other machines put together.

In doing work there are two important points which a practical contractor always takes into consideration—his reputation for quality of work and the cost of labor; and where, in a building, does quality of work and cost of labor "cut more figure" than on the hardwood floors?

Seven years ago the Triple "A" SPRING-DRIVEN Floor-smoother was first introduced in Chicago, and today seventy per cent of all the floor scraping of this great city is being done "The Triple 'A' Way."

The majority of those in the contracting game have learned that it pays to "Triple 'A'" their floors, for by this process *only* can they be sure of maintaining those two essential points of

"High Quality and Low Cost"

Quality of work considered, the cost of surfacing floors "The Triple 'A' Way" is guaranteed to be lower than that of any other method.

ISN'T THAT A GOOD ENOUGH REASON?

If you are not already satisfied that you have the best machine in the world, you had better investigate this **BETTER MACHINE.**

Write now and we will tell you why this Machine does better work at less cost per square.

Up to the Wall and Into the Corners It Goes

Try This Scraper on Your Floors at Our Expense

Here's a Scraper that scrapes clean and smooth, in the corners, close up to the walls, and scrapes without those wavy lines so often caused by "chatter." Our knife with double edge wears twice as long as any other scraper knife. Our adjustable handle, rubber tires and the way the weight is thrown on the knife are all exclusive features of the Stearns No. 10.

We don't ask you to "beware of other Scrapers," but we do ask you to accept this machine on a fifteen day **FREE TRIAL OFFER**, so you may "compare it with other Scrapers," for by test the Stearns is best.

There are fifteen days in which you can test its easy running, smooth shaving and sturdy qualities at our expense.

Write us about it.

Sold by dealers, direct from the factory or on fifteen days' trial. Particulars will interest you.

E. C. Stearns & Co.

400 Oneida St., Syracuse, N. Y., U. S. A.

Why Break Your Back?

Use the Imperial Floor Sander

No more aching knees or back. The Imperial Floor Sander makes floor surfacing easy. Simply a push and a pull and it does the work well.

Load it with twelve sheets of sandpaper. When one sheet wears out cut it off without removing the binder. Don't hesitate to tackle varnish. The Imperial will remove it; it will also resurface and wax floors.

Any carpenter can afford it. Only \$5.00. Does the work of an expensive power machine.

If your dealer doesn't handle the Imperial, we will send one direct upon the receipt of \$5.00.

Isn't This Just the Mortar Mixer You Want?

The Grand Mortar Mixer is always ready to mix and temper mortar at any place. You can take it from one job to another as easily as you can take a wheelbarrow.

It is just as rugged as it looks, being built for long and hard service. The 4 H.P. Engine operates the Grand to its maximum capacity. It will supply 40 to 50 men.

Our catalog tells all about it. Send for our literature.

Hall-Holmes Manufacturing Co.

241 Oak Street, Jackson, Michigan

CONCRETE FOR PERMANENCE

Simplicity is the Keynote

Low charging and consequent simplicity of this machine is the keynote of its efficiency. Its construction does away with the use of complicated side loaders, the drum being charged at its base direct from wheelbarrows from a platform only 24" high. This feature alone means a greater output and reduces the weight of the machine about one-third, enabling it to be moved along the work as it progresses by a few workmen, thereby requiring concrete to be placed with the least handling.

The semi-automatic discharge is controlled from either end of the drum, allowing the entire batch to be discharged direct into forms or a wheelbarrow load at a time. The arrangement of the mixing blades insures quick and thorough mix.

"The Standard" Low Charging

The illustration in the lower right hand corner is from actual photograph of discharge side of "The Standard" mixing mortar for bricklayers. This outfit mixed all of the concrete for the foundation walls of the same structure. "The Standard" will successfully mix cement and lime mortars and plasters at a saving over the old method, but what is more important for brickwork when using this well tempered machine-mixed mortar the men will lay from 10% to 20% more brick.

"The Standard" is built in capacities of from 3 to 40 cu. ft. of unmixed material per batch, mounted with gasoline, steam or electric power.

Low Charging "The Standard" Way Saves One-third in Your Operating Costs

If you are interested in concrete mixers write for Catalog No. 48-7, which describes "The Standard" Low Charging Concrete Mixer in detail.

and Practically Wear-proof, too

THERE are Cortright roofs that have been in successful use for over twenty-five years, and which today have apparently as many more years ahead of them.

Cortright Metal Shingles

are made of red, green or galvanized tin plate and "tight" coated galvanized sheets. They are as easily laid as wood shingles. When down they form a fireproof, stormproof, weatherproof and practically wearproof roof, which needs only an occasional coat of paint to retain these original qualities indefinitely.

Builders all over the country are recommending them, because they make satisfied customers.

We have some special inducements that will interest any builder. Write now for particulars.

Cortright Metal Roofing Co.

Philadelphia and
Chicago

When you are asked about a fire-proof roofing, recommend

J-M Transite Asbestos Shingles

It is alarming to note the thousands of buildings throughout the country with inflammable roofs, each a waiting victim of a stray spark from its own or a neighbor's chimney.

More and more attention is being devoted to safe roofing materials that have all the flexibility of treatment of the more hazardous types.

J-M Transite Asbestos Shingles solve that problem. They are absolutely fire-proof, because they are made of indestructible materials—Asbestos (rock) fibre and cement (rock).

They actually toughen with age and will not crack, rot, split or warp under the most severe climatic conditions.

Made in two thicknesses, in three shapes and several sizes, and with rough or smooth edges—thus affording a great variety of effects in application.

J-M Transite Asbestos Shingles are examined, approved and labelled by the Underwriters' Laboratories, Inc., under the direction of the National Board of Fire Underwriters. Laid American Method, they are given Class "B" rating. Laid French Method, they are given Class "C" rating.

J-M Transite Shingles are furnished in three soft tones—Indian Red, Mottled Brown and Cement Gray.

Ask for literature showing where and how the shingles have been used.

Steel "Stitches" Every Few Inches

Columns which have staves simply glued together will surely open up. Columns which have any kind of a lock-joint are liable to open up. Columns which are glued under hydraulic pressure, where the staves are locked with a double V joint and sewed with cold rolled steel staples every few inches of their entire length *cannot* open up. And this is the way "Steel-Sewed" Columns are always made. Catalog explains the construction and shows many beautiful illustrations. Write for it.

AMERICAN COLUMN CO., Battle Creek, Mich.

OAK FLOORING "AMERICA'S Best Flooring"

Landlords and builders offering houses for sale or for rent command the highest of rentals and hence, the highest class of tenants. They always emphasize OAK FLOORING in their ads in newspapers.

$\frac{3}{8}$ " OAK FLOORING offers a beautiful and very economical floor at a low cost. It is the ideal flooring for laying over old floors in churches and homes. When laid, it has all the appearance of $1\frac{1}{2}$ " stock. $\frac{3}{8}$ " is made in $1\frac{1}{2}$ " face and 2" face.

Contractors and carpenters find it very profitable in soliciting the laying of $\frac{3}{8}$ " OAK FLOORING in old homes during slack periods. Any carpenter, exercising a little care, can lay OAK FLOORING successfully. 95% of modern houses now have OAK Floors. OAK FLOORING is always considered the very best kind of investment.

All reputable lumber dealers sell OAK FLOORING.

Write for Booklet—"America's Best Flooring."

A Convincing Demonstration of North Carolina Pine Utility

The above is an excellent illustration of the North Carolina Pine Bungalow, a full size 8-room house, built as an exhibit, at the Country Life Permanent Exposition, Grand Central Terminal, New York City.

It is built throughout, from ground to roof, of North Carolina Pine, and, as it stands, constitutes a more powerful argument for the rare beauty and sterling quality of this wood than any words could possibly convey.

When you visit New York, we invite you to inspect this delightful example of comfort, refinement and architectural perfection. You will find it of distinct and practical helpfulness. No admission fee is charged and no obligation incurred.

Write for our Free Reference Book B, which tells more about this splendid wood. A postal will bring it.

Photo by Mary H. Northend, Salem, Mass.

JOHN WARD HOUSE
at Salem, Mass. Built in 1684.

Words could not portray the lasting qualities of White Pine as graphically as this remarkable photograph. The exact date of the unpainted, weather-beaten siding is not known, but it is certain that the siding on the main portion of the house is from 150 to 200 years old, and stands now as originally built, with practically no repairs. The siding on the lean-to is of a considerably later date, but it will be noted that there is no appreciable difference between it and the siding on the main portion of the house. Both are in splendid condition today and good for service for many years to come.

FOR the outside covering of a building exposed to the attack of time and weather, no other wood gives such long and satisfactory service as

WHITE PINE

Every carpenter knows that from his own experience. But every carpenter does not know that he can get White Pine today, for in some way the impression has gained footing that the supply of White Pine is practically exhausted.

The fact is — White Pine is still abundantly available today, as it always has been, in all grades and in any quantities desired, and can be purchased in all markets at reasonable prices, when considering its value as a structural wood.

If the Lumber Dealers supplying the material for those for whom you are building are at any time unable to furnish it, we would appreciate the opportunity of being helpful in securing it.

A Free Magazine for Contractors

The first issue of the bi-monthly architectural White Pine Magazine has been mailed to contractors. Every issue will be full of valuable and helpful information for contractors and builders.

If this magazine does not reach you, kindly advise and we will be pleased to place your name on our mailing list.

Walls finished with Cabot's Old Virginia White
Roof finished with Cabot's Creosote Stain
"We are using the same stains on other houses with equally satisfactory results."—Herbert Foltz, Architect, Indianapolis

A New Style in Country Houses

Our leading architects are now designing a new and dignified type of country-house, along fine old Colonial lines. The roof is shingled, and large shingles, in single or double courses, cover the sides. The roof shingles are stained in moss green, tile red or slate gray tones of

Cabot's Creosote Stains

and the sides with

Cabot's Old Virginia White

which is as cool and brilliant and soft as new whitewash, and as lasting as paint. The stains are rich and handsome, and the combination is harmonious and appropriate.

Cabot's Quilt

Makes houses warmer in winter and cooler in summer. The U. S. Bureau of Standards' tests proved it the most efficient heat insulator, even better than cork board. As a sound-deadener it is equally efficient.

You can get Cabot's Stains and Quilt all over the country. Send for samples and names of nearest agents.

Section of Outside Wall of House, Showing Wool Between Studding.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

U. S. Mineral Wool Co.

NEW YORK, JULY, 1916

A Stucco-Coated Frame Residence

A Well Considered Plan to Meet the Requirements of a Physician—Details of Construction

THE design which forms the basis of the present article represents the home of a physician on Long Island, N. Y., and embodies features of arrangement of special interest to those having to do with the construction of dwellings of this nature. Noticeable features of the external treatment include the broad veranda, extending en-

tering the main hall through the vestibule one finds at the left and separated by folding doors the office of the physician-owner, measuring 8 ft. 8 in. x 12 ft. in size. Opening from it at the rear is a lavatory with a medicine cabinet and lighted by an outside window immediately over the washbasin. Just at the left of the vestibule door and opening

Residence of Dr. Ernest Goode at Bayside, Flushing, N. Y.—Architect, Geo. J. Hardway

tirely across the front of the building, the massive columns supporting it, the gambrel roof with its protruding dormers, which break the roof surface and the outside chimney of cobblestones.

The floor plans presented on another page show a compact and well-considered arrangement. En-

tering the main hall through the vestibule one finds at the left and separated by folding doors the office of the physician-owner, measuring 8 ft. 8 in. x 12 ft. in size. Opening from it at the rear is a lavatory with a medicine cabinet and lighted by an outside window immediately over the washbasin. Just at the left of the vestibule door and opening

Miscellaneous Constructive Details of a Stucco-Coated Frame Residence

with its beam ceiling, the striking feature being the open fireplace built of split field stone with cement hearth. Beyond the living room and communicating with it through an open colonnade is the dining room, the walls of which are finished in slatted panels 6 ft. high, extending to the plate shelf. Communication between the dining room and kitchen is established through a well-equipped pantry lighted by an outside window. In one corner of the pantry near this window is the space for the refrigerator. The kitchen requires no chimney connection, owing to the fact that a gas range is used for cooking purposes.

On the second floor are four sleeping rooms and bathroom, this being so located as to result in an economy of installation of plumbing fixtures.

The foundation walls are of concrete mixed in

around openings for dormers. The floor joists are stiffened with $1\frac{1}{8}$ x 2 in. herringbone cross-bridging, and the frame of the house is diagonally braced with 2 x 4 in. stuff cut in between the studs. The floor joists of the porch decks are 2 x 8 in., also spaced 16 in. on centers.

The exterior frame of the building is covered with 8 x $\frac{7}{8}$ in. matched and surfaced spruce boards laid diagonally, cut on the bevel on bearings and double-face nailed at each bearing. To the sheathing boards is fastened metal lath to which the cement stucco coating is applied. The roof rafters carry 1 x 2 in. shingle strips to which are nailed 16 in. cedar shingles exposed 5 in. to the weather on the sharp pitches and 4 in. to the weather on the flat pitches. The ridges are covered with shingles laid Boston style woven.

A Stucco-Coated Frame Residence—View in the Dining Room Looking Toward the Casement Doors Leading to the Pergola at the Rear

the proportion of one part Portland cement to five parts coarse gravel and sharp grit sand.

The framing timbers are of spruce, the sills being 4 x 6 in. and the center beam or girder 6 x 8 in., all halved and spiked together on corners and joinings and supported on Acme columns with iron caps and bases.

The first and second floor joists are 2 x 10 in., and the third floor joists 2 x 8 in., all spaced 16 in. on centers. They are doubled under partitions and around openings for stairs, chimney, etc., using stirrup irons for headers and trimmers.

The studs are 2 x 4 in. spaced 16 in. on centers, tripled at corners and doubled around openings with truss over openings more than 4 ft. wide. The plates are 2 x 4 in. doubled and the rafters are 2 x 6 in. spaced 16 in. on centers and doubled

The porch columns are slatted up on circular forms covered with metal lath and finished in cement, painted white. The floors of the porches are of concrete laid on a cinder base and marked off in areas about 2 ft. square. The porch ceilings are laid with $\frac{1}{2}$ x $2\frac{1}{2}$ in. face cypress ceiling and finished with $\frac{7}{8}$ x 2 in. mold at the intersections. The bedroom floors over the porches are thoroughly packed with mineral wool and made airtight.

The cellar, which extends under the entire building, has a floor of concrete 4 in. thick. In the cellar is located the laundry with a set of Alberene soapstone wash trays, 28 x 28 in., on galvanized iron stands, and a gas laundry stove. There is also space for the hot water boiler and the water heater, a fuel bin and a room for fruit and vegetables.

The chimney is of brick laid up in lime and ce-

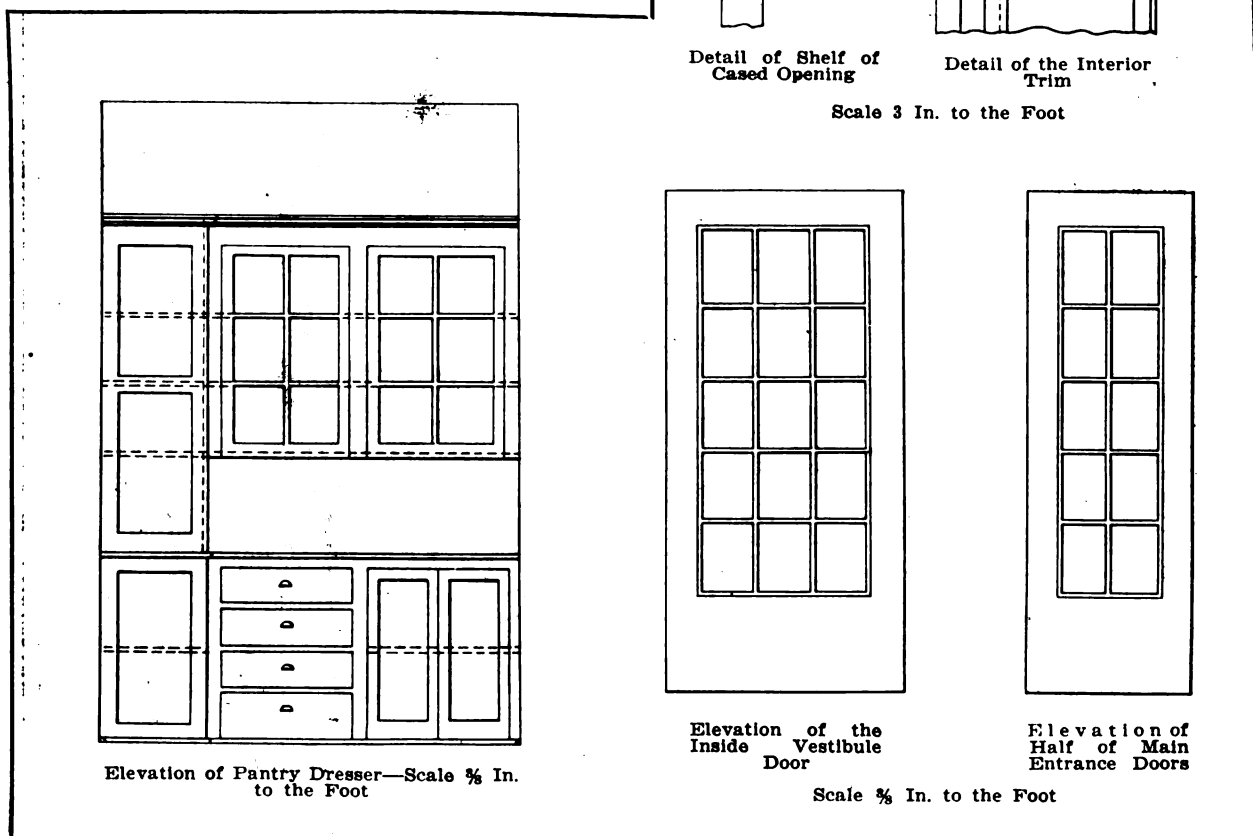

ment mortar and with all exterior joints neatly struck. The exterior exposed surfaces are built up with cobblestones and all flues have terra cotta linings extending from the bottom to the top of the chimney. An idea of the appearance of the chimney may be obtained from inspection of one of the small halftone pictures near the end of this article.

All walls and ceilings of the rooms on the first and second floors are plastered with two coats of King's Windsor Cement mortar and finished with a white coat of King's Windsor Cement, all applied to spruce lath. The walls of both bathroom and kitchen are covered 5 ft. high with metal lath and plastered with King's Windsor Cement. The finish coat is of Keene's white cement laid off in the kitchen in imitation of 3 x 6 in. tile.

The window sash are 1 3/8 in. white pine glazed with double strength American glass, balanced with weights and hung with Silver Lake cord over pulleys. French windows have 1 3/4 in. sash hinged at side and finished with bronzed butts and fastenings. All outside finish, corner boards, casings, mold-

finish 7/8 x 4 3/4 in., terminating with a molded cap. The treads of the stairs are 1 1/8 in. thick, with molded nosings, and the risers are 7/8 in. thick. The strings are 1 1/8 in. and all are housed together, thoroughly wedged, blocked and glued.

The balance of the finish is No. 1 whitewood of the same design and the doors are of birch. The

Miscellaneous Constructive Details of a Stucco-Coated Frame Residence

ings, porch work, exposed rafters and hanging rafter pergola are of cypress.

The floors of the kitchen and pantry are 7/8 x 2 1/2 in. matched maple flooring; those of the second story are of 7/8 x 2 1/2 in. face edge grain North Carolina pine laid on a diagonal sub-floor, while the third story floors are of 3-in. North Carolina pine, blind nailed.

The balance of the first story floors are double, the sub-floors consisting of 6 x 7/8 in. surfaced spruce flooring, laid diagonally, and over which is laid parquet flooring of oak.

The finish of the office, living room, dining room, hall and stairs is oak with a plain single member

finish in the kitchen and the third story is cypress.

The doors throughout are of the five cross-panel variety, and are 1 3/8 in. thick.

The soffits of all overhanging eaves are ceiled with cypress ceiling.

The side walls of the bathroom are covered with 6-in. glazed tile, with sanitary cove, while the floor is laid with 1 1/8-in. vitreous octagon tile. The bathroom equipment consists of an enameled iron lavatory, 22 x 33 in. in size, and resting on an oval pedestal, a 5 1/2-ft. roll rim enameled tub with nickel-plated fittings, and a vitreous china syphon closet of Standard make.

On the third floor is a service lavatory, 22 x 22

in. in size, of enameled iron. In the kitchen is a 20 x 30-in. enameled iron flat rim sink with compression faucets and nickel-plated strainer. In the basement is a wash-down water closet, and in the laundry is a 16 x 16 x 6 in. cast iron slop sink, with strainer and cast iron trap.

All interior oak finish was given a Flemish stain,

A Stucco-Coated Frame Residence—End View Showing the Outside Cobblestone Chimney

while all interior cypress received one coat of shellac and two coats of varnish. All interior white-wood finish was given four coats of flat white one-half zinc and one-half Atlantic white lead finish. The white cement tile of the bathroom and kitchen were given two coats of "Superior White Enamel," over one coat of flat white "Jap-a-lac." All wood-work in the basement received two coats of lead and oil paint.

All exterior woodwork not otherwise specified received two coats of lead and oil paint after the priming coat. The ceilings of the porches were finished with a coat of bleached shellac and two coats of exterior varnish. The shingles of the roof were dipped 10 in. in Cabot's shingle stain before being laid, and they were given a brush coat when the house was finished. The stucco finish received two coats of Cabot's stucco stain. All tin and iron work was given two coats of lead and oil paint after the priming coat.

The house is piped for gas and wired for electric lights in accordance with the rules of the Board of Underwriters. In the lower hall are three way-switches to control upper hall and vice versa; also a switch in the kitchen to control one light in the basement and a switch to control one porch light. In the kitchen is a 4-point enunciator with drops indicating side door, rear door and upper hall; also a buzzer with push in the dining room floor.

The house is heated by a Richardson & Boynton hot water boiler of sufficient size to maintain a temperature of 70 deg. in zero weather. The pipes supplying the radiators upon the first floor run in the partitions and are covered with heavy asbestos.

The residence here shown is that of Dr. Ernest W. Goode, at Bayside, Flushing, N. Y., and was erected in accordance with plans and specifications prepared by George J. Hardway, architect, 347 Fifth Avenue, New York City, and the work of construction was carried out under his supervision.

Romanesque Architecture

In a lecture on "The Architecture of Portugal" delivered not long since before the London Architectural Association, W. H. Ward of the Royal Institute of British Architects pointed out that the earliest examples of Romanesque architecture are naturally found in the north, and consist of an exceedingly simple and rude type of churches of the eleventh and twelfth centuries, with rectangular naves and chancels and occasionally a northern porch. Among other things he said:

"After the foundation of the cathedral of Santiago de Compostella, which was probably modeled on S. Sernin at Toulouse, a more developed basilican plan, with a transept projecting beyond the aisles and apses on the east side of it, became established as the national type, varied in a few of the more important later Gothic churches, such as the cathedral of Lisbon, by a chevet with radiating chapels. An admirable example of the Romanesque style, though dating from quite the close of the twelfth century, is the old cathedral, or *Se Ve Velha*, at Coimbra, with its austere fortress-like exterior almost unpierced by windows and crowned by battlements, and its long, dimly lit nave, culminating in the glory of an apse rich in carving and gilding. All the light comes from the high west window and two in the domical lantern at the intersection, which, externally, is still clothed with a mosaic of self-colored tiles. Internally, the aisle walls retain the patterned tile lining which has been stripped from the piers during a recent 'restoration.' The piers have half-round engaged shafts with capitals of Byzantine character. There is no clerestory, and the barrel vault of the nave is buttressed by half-barrel vaults over the quadripartite aisle vaults.

The Fireplace and Seat at the End of the Living Room

The three apses of the old cathedral are enriched with alter-pieces, probably the work of a colony of Flemish artists, who were employed by Manoel the Fortunate. The central one is in wood, and consists of exuberant Late Gothic canopy work gilded on a blue ground. Those in the side apses are of stone, and of the Early Renaissance, executed by Flemings or Frenchmen. The beautiful font near the west

end appears to be the work of Jean de Rouen—a Frenchman who came to Portugal about 1521, after having worked upon the monument of Cardinal of Amboise at Rouen.

"The transition from Romanesque to Gothic has its finest example in Portugal—as it has in London—in a church of the Knights Templars. This circular, or, rather polygonal, church at Thomar was built about 1165, and therefore probably earlier than the still fully-round-arched cathedral at Coimbra. The most important building of Early Pointed architecture in Portugal is contemporary with the last two. This is the great Cistercian Abbey Church at Alcobaça, founded in 1165, and finished 1211, and begun at least by Frenchmen.

"The influence of Northern Gothic was for a long time very slight in Portugal, and the thirteenth century, which was such a splendid building age in northern Europe, was almost barren here. Most of the earlier Pointed buildings date only from the fourteenth century. To this period belong many of the beautiful cloisters which offer one of the great charms of Portuguese churches.

"The fine church of Sta Clara at Coimbra, now half-silted up by the floods of the Mondego, is another example of fourteenth century building, which, from its massiveness and simplicity, and the absence of tracery, looks as if it belonged to the thirteenth, or even the twelfth. Much, too, of the picturesque castle of Leiria and its beautiful ruined chapel was built in the fourteenth century by King Denis the Laborer, who earned his name by his unremitting efforts to reclaim large tracts of waste land and plant the sand dunes. One of the first symptoms of Portuguese Gothic getting abreast of that of other countries is to be found in two beautiful altar tombs at Alcobaça, made about 1390, almost certainly by foreign, and probably by French, craftsmen. They are the tombs of Dom Pedro I and his mistress, Inez de Castro, who was murdered in the garden near Coimbra."

Compressive Strength of Portland Cement Mortars and Concrete

A publication has just been issued by the Bureau of Standards, Department of Commerce, on the "Compressive Strength of Portland Cement Mortars and Concretes," which will be of interest to contractors and engineers, and, in fact, to all users of cement.

Concrete differs from most structural materials in that it is not manufactured at a mill or plant according to chemical formula, under the observation of skilled specialists, subject to rigid inspection and test and such control as to produce a uniformly homogeneous product; nor is the process of manufacture completed in a few hours or days, as in the case of steel products. Furthermore, concrete is made from materials obtained from sources differing widely in characteristics which affect its quality. The proportions of the ingredients, the amount of water used in mixing, the thoroughness of mixing, the manner of placing, the atmospheric temperature and humidity, exposure to sun, rain and wind, immersion in fresh or sea water, all affect the quality of the concrete.

All these matters are discussed in the Bureau's

publication which contains the results of some 20,000 tests. The general effect of variation in the methods of preparing the concrete is shown, and suggestions are given as to the proper methods to follow to obtain the best quality of concrete.

Many users of cement believe that the strength of concrete is entirely dependent upon the quantity of cement used in the mixture. This is not true, as a mixture lean in cement but properly made may have much greater strength than a rich mixture improperly prepared.

While there are not a great many failures of concrete structure, the majority of those which do occur are due to careless methods of preparing and placing the concrete, or ignorance of the effect of variable treatment. Most of the concrete used in building construction work to-day is mixed with an excessive quantity of water which permits of economic transportation from the mixing plant to the forms by means of shutes and troughs, but this excess of water may result in reducing the strength 50 per cent or more from that which could be obtained by using a lesser quantity of water.

The paper states that certain generally accepted methods of testing aggregates and proportioning mixtures are incorrect and suggests methods of selecting concrete aggregates, proportioning the mixture, mixing, placing and curing.

Copies of the publication known as *Technologic* paper No. 58, may be obtained free upon request to the Bureau of Standards, Washington, D. C.

Implement Sheds for the Farm

An attractively covered and amply illustrated pamphlet on Implement Sheds, written by Prof. K. J. T. Ekblaw of the College of Agriculture of the University of Illinois, is the first of a series of Bulletins on farm buildings being prepared by construction engineers for the National Lumber Manufacturers' Association, the series of nine in all on various buildings about the farm being so prepared that they can be bound in a single volume if the farmer wishes to preserve them for future reference.

The publication on Implement Sheds, like the others which will follow it, goes deeply into the question of how to construct buildings for the farm of sufficient strength and durability to prove in the highest degree economical for the builder.

The author, in addition to his technical suggestions, lays down as a general proposition the advisability of painting the farm buildings, for preservation against weather, insects, or other destructive agencies, as well as to give the farm a prosperous appearance. He says also that an implement shed can be erected in such a manner as to be simple, artistic, and utilitarian. His pamphlet gives hints for the erection of open, simple, two-story and wide inclosed types. It is published by the National Lumber Manufacturers' Association, Chicago, Ill., and copies are sent free on request.

The Rotch traveling scholarship has been awarded to R. T. Walker, a Boston architect, who will receive \$1,500 annually for two years to defray expenses of a tour abroad for the study of architecture. The test consisted of a design for a concert hall. A second prize of \$75 was awarded to H. Moise.

Some Aspects of Modern Shingling*

The Professional Shingler and His Work—Handling the Shingles—Splitting of Wide Shingles

By EDWARD H. CRUSSELL

WE have already stated that the professional shingler often prefers to get right on to the roof instead of working the first courses from a scaffold, and Fig. 15 is a photo showing one of these fellows just commencing his job. It will perhaps be noticed that he breaks open his bundles as he uses them, but that is only because he is expecting some help on the job, and each man will be paid for the bundles he lays.

There has been considerable discussion in the past regarding the speed of the professional shingler and the quality of his work, and while disclaiming any desire or intention to start an argument, the writer would yet like to be permitted to turn aside from the main subject long enough to say a few words upon this much-discussed topic. Let me begin

whereabouts is at present unknown and whose very name has been forgotten.

First, as to speed. I have seen two men on the same job—one a professional shingler, the other a carpenter—each put on 8,000 shingles in ten hours. This is the best performance I have seen, but I know positively that it is nothing like a record, and can be and frequently is beaten. The shingles were of redwood, fastened with 3d common nails. They were laid under my supervision, and the work had to be first class. Rows straight, two nails to every shingle, the joints broken at least 1 in., and all shingles split that were 8 in. or more in width.

There are many people who, never having seen the professional shingler at work, refuse to believe the stories of his speed and accomplishments. A

Fig. 15—A Shingler Just Starting Work on a Roof

Fig. 16—Method of Holding the Shingles by the Workman

Some Aspects of Modern Shingling—The Professional Shingler

by saying that I have nothing either to gain or lose in this matter, and that if I did not feel sure my readers (or at least those who are acquainted with my previous writings) would take my statements at face value I would sidestep this part of my subject altogether. It certainly would be foolish for any writer to risk whatever small reputation he might have for veracity and accuracy for no other purpose than the boosting of some nail-driving expert whose

favorite method of those who attempt to disprove the statements is to first figure how many nails are required to nail a certain number of shingles, and then, calculating one nail per second, prove by figures that "it can't be done."

The chief thing wrong with this method of argument is the fact that comparatively few people have any real idea of the length of one second and of what may be accomplished in that length of time by one who is really trying. Counting at ordinary talk-

*Copyrighted, 1916. Edward H. Crussell.

ing speed it is easily possible to count one two three four, to the second and *anyone* who uses a hammer in his daily work ought to be able to strike light blows at least that fast—two blows to the nail and two nails to the second.

Another argument offered is that the professional's work is not fully nailed, one nail to two

Some Aspects of Modern Shingling—Fig. 17—Showing That Wide Shingles Do Not Always Split After Laying

shingles, and so forth. Nailing is the least of the professional's worries; he carries his nails in his mouth and has an educated tongue, with which he can push two nails at a time, point foremost, from between his lips as fast as he is able to drive them. He has practised this so often and does it so automatically that if for any purpose he needs an extra nail you will always find him using two.

This is not exaggeration, but a sober fact. The entire process of bringing two nails from the mouth and driving them with four successive blows of the hatchet is such a mechanical one that if he should drive one nail into a shingle and then drop the other instead of reaching for one nail, as you or I might, he takes the two already protruding from his lips and drives them with exactly the same motions as he would if the one nail was not already in place. Almost invariably the professional shingler's work is both faster and better than that of the carpenter, as any unprejudiced person would naturally expect it to be.

Now why have I gone aside to discuss this matter? Because if we approach the solving of any problem with an "It can't be done" attitude we have already invited failure, while if we can first get ourselves to believe that it *has* been done, and then assume that what one man has done another can do, the biggest portion of the problem is already solved. If therefore (this is for the younger readers) you wish to speed up your shingling abilities, commence by believing that what has been written concerning the professional shingler in the foregoing is true.

Let us return to our main subject and see if we can discover what advantages the fellow with a gauge on his hatchet, carrying six or seven courses at once, has over the fellow using one of the other methods. The first saving, of course, is in the lesser need of chalking the line. The next is in walking backward and forward across the roof. But the biggest saving of all and the one most frequently overlooked is the ease with which he is able to place his shingles and keep the joints broken. This is because he has as many places to lay any shingle as he is carrying courses, and it would be a queer shingle that would not fit in one of them. The man carrying a single course has only one place to lay

his shingle, and if it doesn't fit he must exchange it for another or trim it to size.

For the actual handling of the shingles there are different methods used, even by the professionals. Some prefer to take the shingles one or two at a time from between the roof boards, selecting the correct width as they do so. Others take each small package from between the roof boards as they come to it and lay it across their lap, as in Fig. 16. In this latter method pressing the shingles edgewise against the thigh will discover the widest one, and this is laid on the bottom course, then the next widest is laid on the second course, and so on.

To keep the courses straight the far corner of the shingle about to be laid is gauged with the hatchet from the course below, while the near corner is kept in line with the shingle already laid in the same course.

The adjustment is made almost instantly and automatically, and the hatchet is then turned over so that the head of it rests on the shingle and holds it in place, while the left hand goes for nails. The outer edge of the left hand now rests on the shingle and holds it so that the hatchet may be lifted. Between the thumb and forefinger of this hand are held the two nails, a slight distance apart, the outer nail already over the place where it is to be driven; as soon as the first nail has been started the hand moves with the other nail to its appointed place. All the motions are as automatic and as certain as those of a piano player, and, as already stated, the two nails are driven with four blows of the hammer about as fast as you can count rat-tat—rat-tat.

No great difficulty is made of the splitting of wide shingles. The shingle is usually placed as if it was not to be split; two nails are driven into that half of it nearest the workman, the further edge is then lifted with the left hand and a tap with the hatchet splits the shingle. The second half is then moved over a little to make a joint and two more nails are driven into it.

The slight extra width made by splitting a shingle is sometimes taken advantage of and used

Fig. 18—Another Section of the Same Roof as That Shown in Fig. 17

for increasing the width so as to give a little more lap to the joint, when, had it not been for the extra width required the shingle would not have been split.

The splitting of wide shingles when laying them is an item that has received some consideration in the past. The idea seems to be that if they are not split when laid they will split afterward and may split directly over a joint and so cause a leak. That wide shingles do not always split after they are laid is pretty well proven by the photo Fig. 17.

The shingles in this picture had been on about five years when one day the roof caught fire from a defective flue. When repairing the roof the attention of the writer was drawn to the number of wide shingles in it and to the fact that apparently they had no more tendency to split than the narrow ones had.

Every shingle marked X in the photo is 12 in. or more in width, as may be proven by comparing them with the 2-ft. rule shown open on the roof, and not all of the wide shingles have been marked. The two shingles marked O had new fractures, proving that they had been broken either by the firemen or by the workman doing the repairing. The exposed portion of the one shown at the left consisted entirely of cross grain and knot, and this shingle should never have been laid. Fig. 18 shows another portion of the same roof, merely to prove that the wide shingles without splits were not confined to one small section of it.

Since seeing this roof the writer leans to the opinion that the chief advantage obtained by split-

ting the shingles is about the same as that gained by using narrow, rather than wide, flooring, viz.: more nails and the swelling and shrinking divided amongst a greater number of joints.

In those parts where there is a wet and a dry season, great care must be exercised in spacing the shingles. Those laid in the summer, when they are very dry, need to be spaced so that they may not swell tight and buckle up when the winter rains appear. On the other hand, those laid when they are very dry, need to be spaced so that they may not swell tight and buckle up when the winter rains appear. On the other hand, those laid when they are very wet, must be laid close and require judicious nailing in order that the long months of summer sunshine may not open up the roof and make it a sieve. Of course shingles, when perfectly dry, should not be laid close in any climate, but only those who have lived where the spring and fall rains are five months apart have any idea of how exceedingly dry shingles, and shingle roofs, may become.

(To be continued)

A Farm House for a Small Family

A Design Prepared to Meet Requirements of the Southern Climate—Sleeping Porch a Feature

THE design of farm house here illustrated and described represents the results of extensive surveys in the South to determine the household needs of families with reference to local agriculture, climate and domestic help. The materials selected are those commonly used in that section of the country, and in the development of the plan

portant rooms. The dresser or china closet, as it may be termed, opens into both rooms and results in the saving of a great many steps between the two, owing to the fact that after meals dishes may be passed through on the wide counter shelf to the kitchen, where they are washed at the sink placed in close proximity and amply lighted by the double

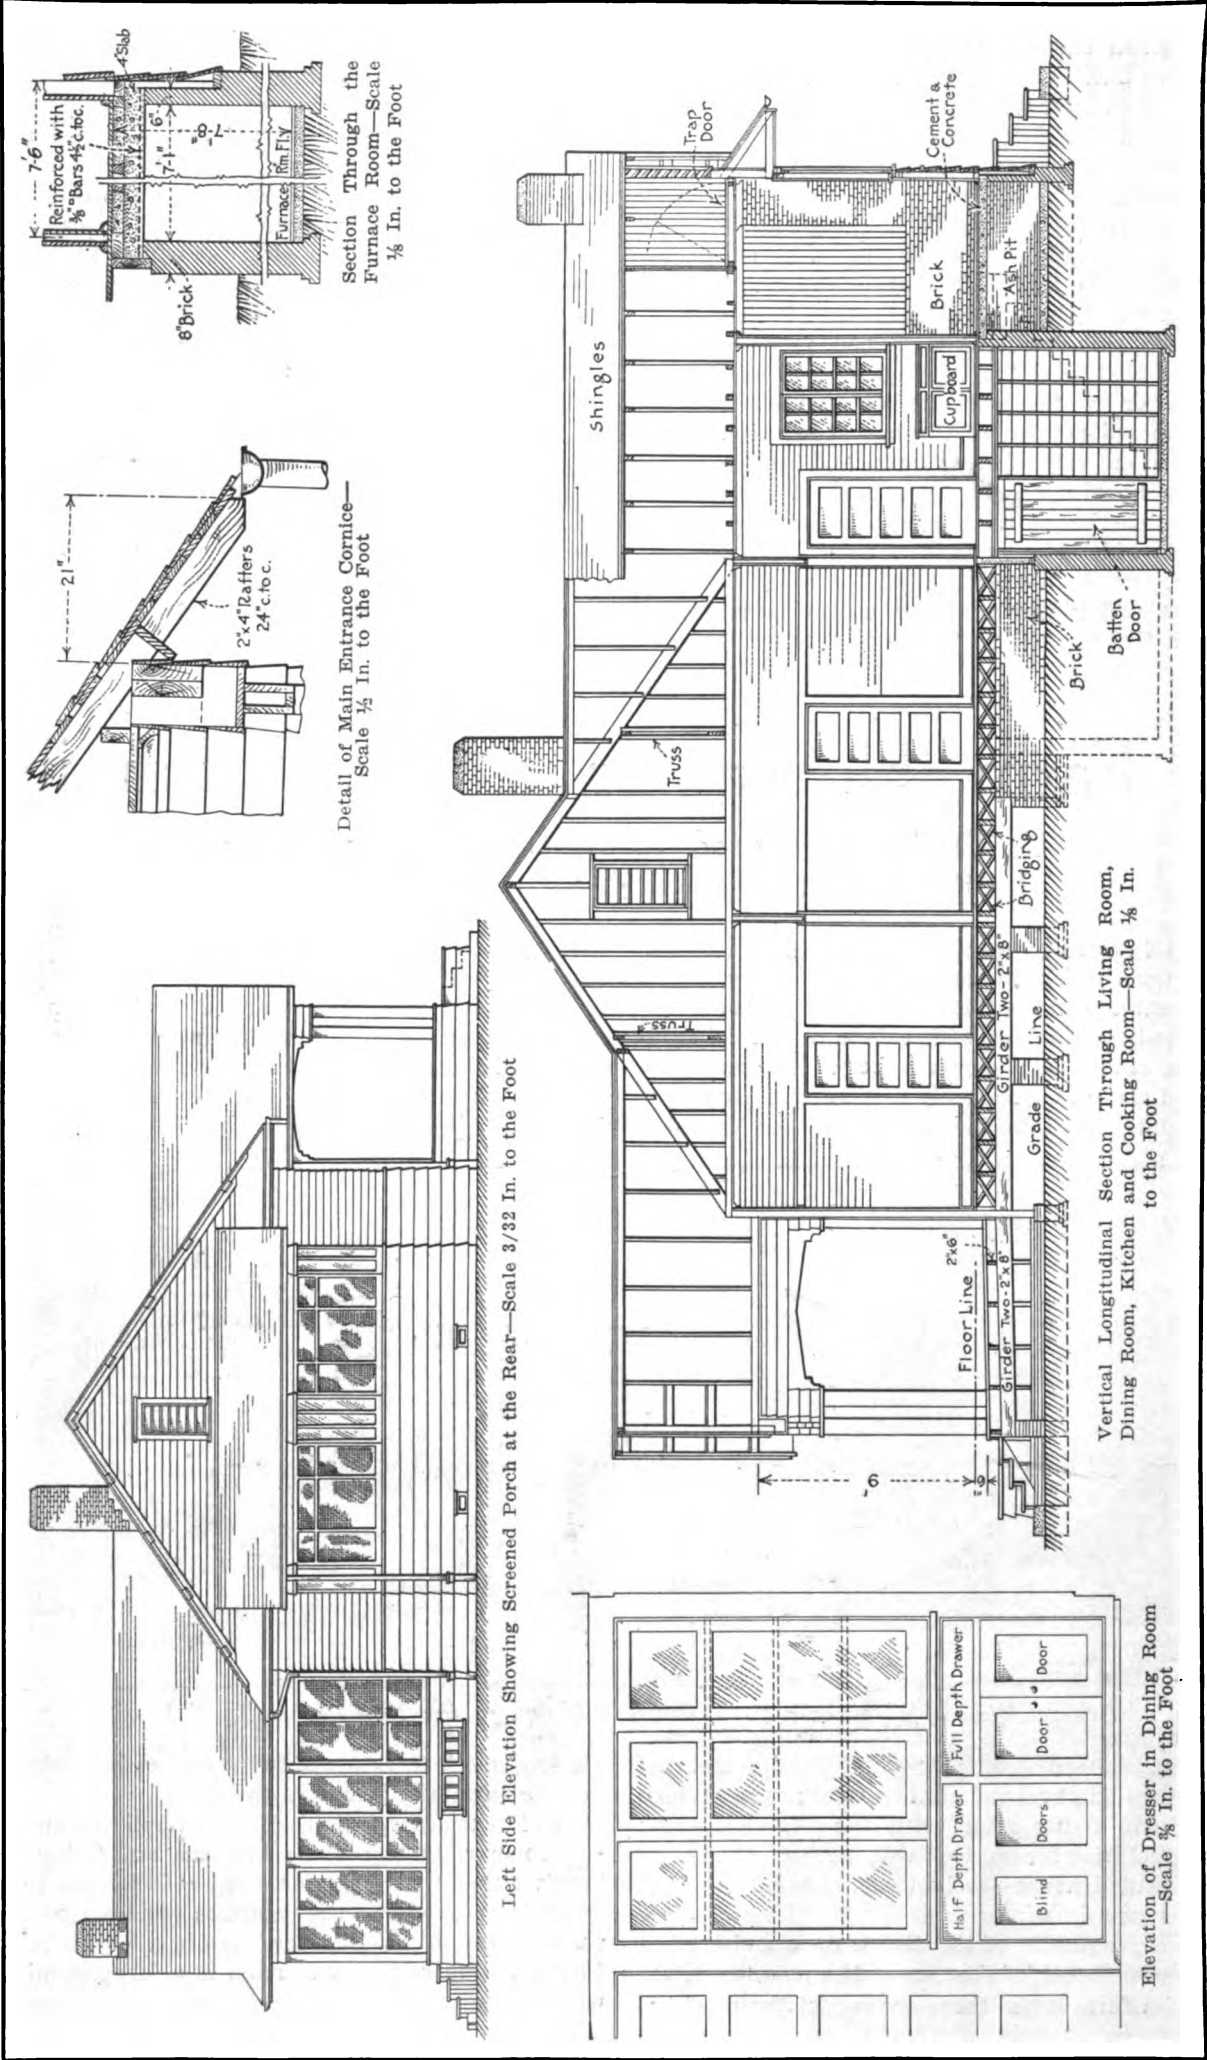

General View of a Southern Farm House Adapted to the Needs of a Small Family

the aim primarily was to provide, first, a cool and convenient kitchen and dining room; second, bedrooms and living room with the best exposure; third, facilities for outdoor sleeping, and fourth, an easily heated house—cool in summer and yet with sunny rooms in winter.

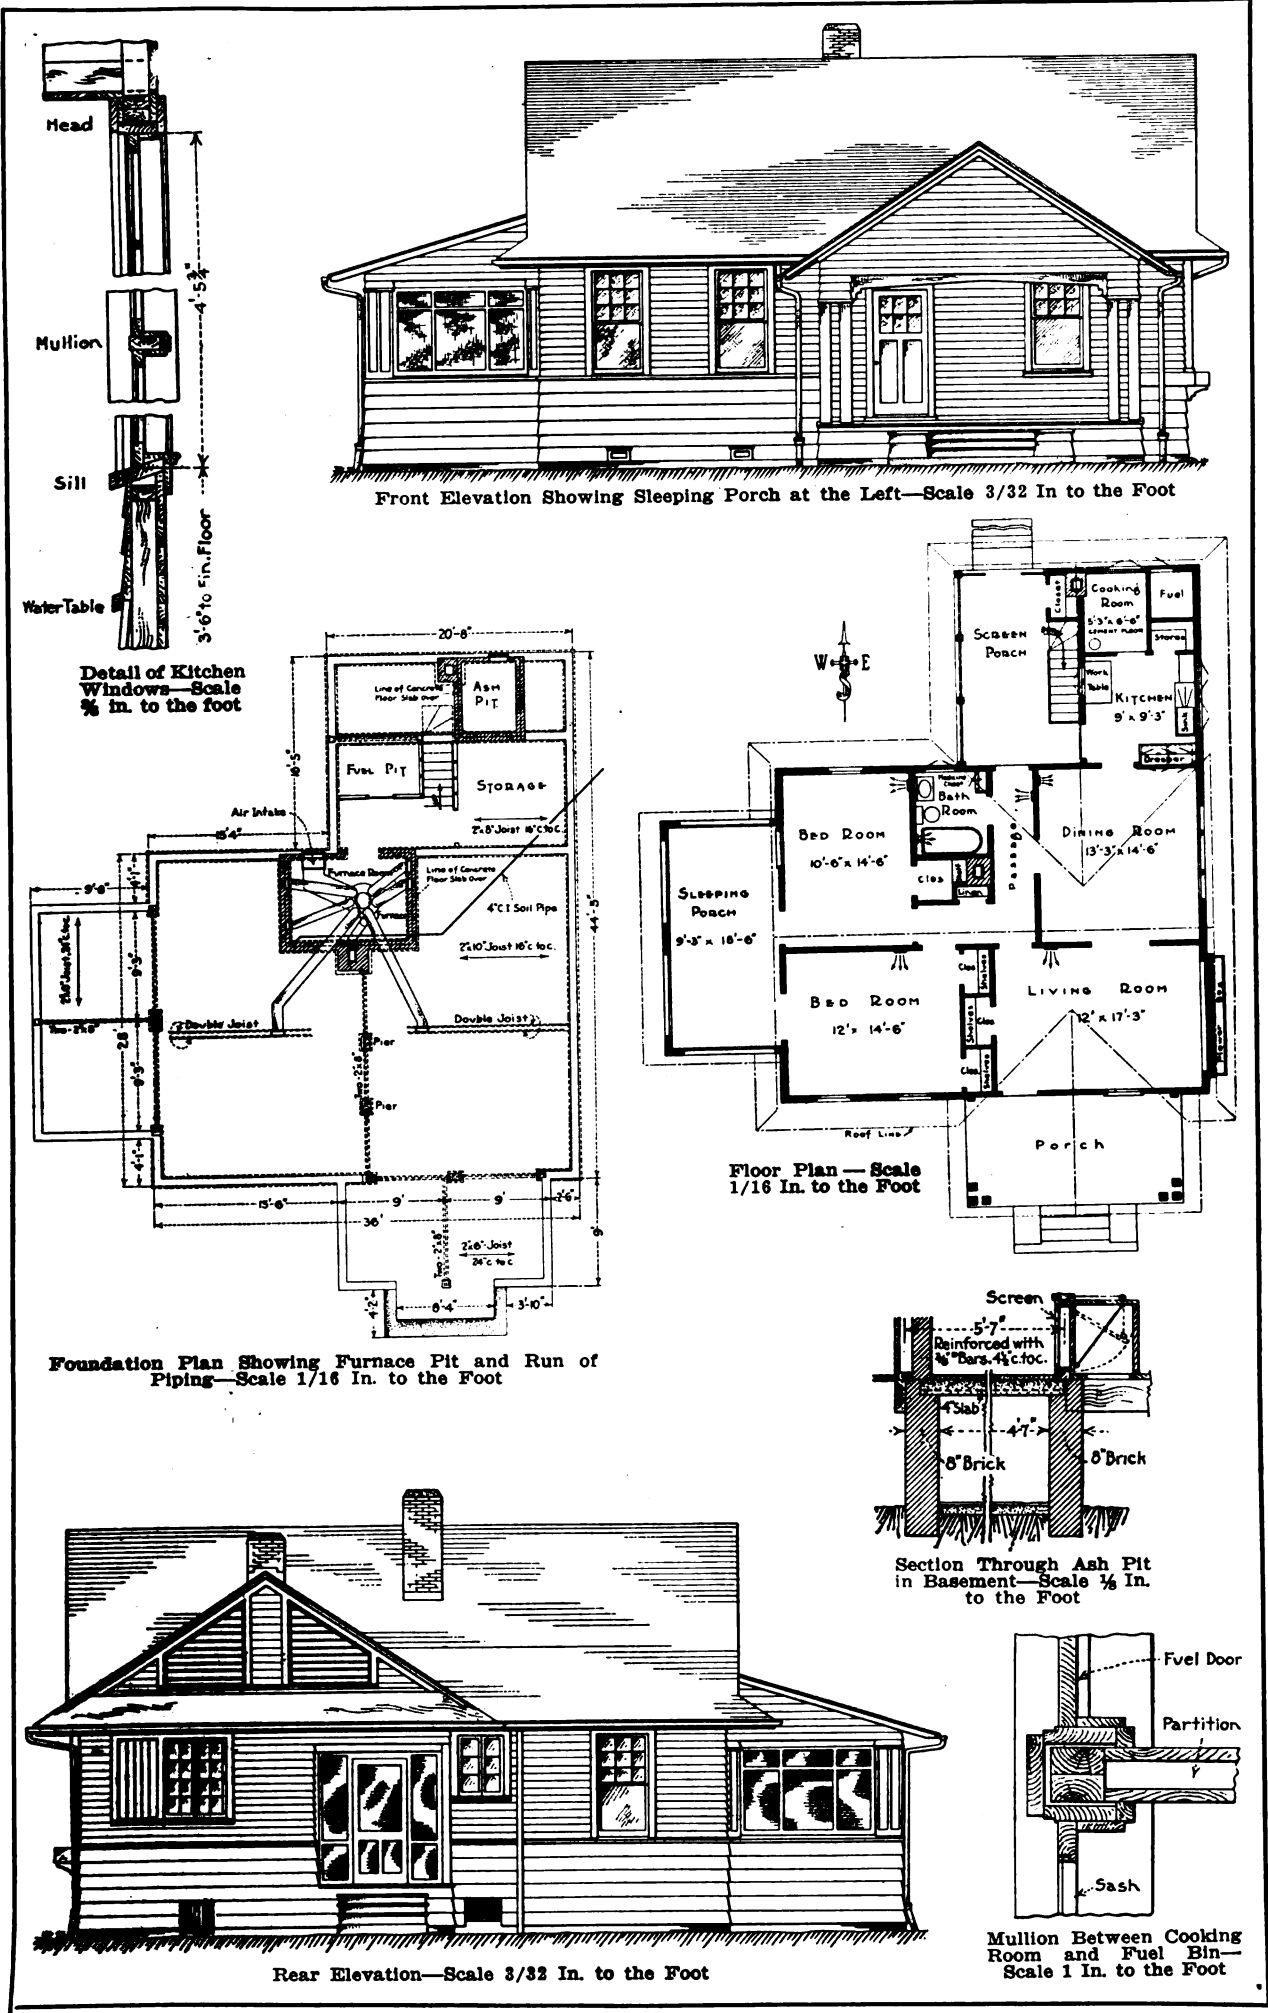

The arrangement of the dining room and kitchen constitutes the chief feature of the plan, as in the case of a farm house these are two of the most im-

portant rooms. The dresser or china closet, as it may be termed, opens into both rooms and results in the saving of a great many steps between the two, owing to the fact that after meals dishes may be passed through on the wide counter shelf to the kitchen, where they are washed at the sink placed in close proximity and amply lighted by the double

window, and then returned to the china closet where they are available from either side. The kitchen is well lighted, conveniently arranged and comparatively cool as kitchens go, owing to the fact that the range for cooking is located in a separate room at the rear and the windows on opposite sides of the kitchen permit a cross-draft. In the ceiling of the cook room is a large opening which permits the heat and odors to escape through

A Farm House for a Small Family—Elevation, Longitudinal Section and Miscellaneous Constructive Details

A Farm House for a Small Family—Plans, Elevations and Miscellaneous Constructive Details

a ventilator in the gable. Near the stove, to give light and air, is a double casement window. A grated opening near the floor in the wall between the cook room and the kitchen closet draws air from below the floor and promotes circulation from the floor upward, thus helping to keep the lower part of the room cool. In winter when it is desired to keep the heat in the house the door between the cook room and the kitchen may be kept open and the ventilator and grate closed. The separate cooking room also insures a dining room which is cool and free from odors. The fuel room filled from outside is conveniently at hand, thus obviating carrying in fuel every day.

The living room occupies practically one-half the front of the house and is reached directly from the porch, no vestibule being considered necessary in the Southern climate. Communicating with the living room is a passageway leading directly to the screened porch at the rear. Opening from this passageway at the left are two sleeping rooms and bathroom. At the extreme left and opening out of both bedrooms is the sleeping porch, measuring 9 ft. 3 in. x 9 ft. 6 in.

The position of the bathroom is such that it is readily reached from all parts of the house, and at the same time is accessible from the screened porch without the necessity of passing through any other rooms. The closet opening off the screened porch is intended for rubber coats, boots, etc. As the house shown is designed to meet conditions prevailing in the South no provision was made for "washing up" by the farmhands, as they, as a rule, have their own quarters.

In the basement is located the furnace for heating purposes and the foundation plan clearly indicates the run of the pipes. The heater is placed in a pit beneath the bathroom, and the statement is made that the cost of installation would not greatly exceed that of two chimneys with two open fireplaces which would be necessary to heat all the rooms if open fireplaces were used for heating purposes. The pit is constructed of concrete and is made waterproof. Directly over the heater is a concrete floor slab.

The floor joists under the kitchen are 2 x 8 in. placed 16 in. on centers, while the floor joists for the other rooms are 2 x 10 in., also placed 16 in. on centers. The girder extending from the front wall of the house to the chimney base and supported on piers consists of two 2 x 8's. The joists are doubled under bearing partitions. The joists of the sleeping porch are 2 x 6 in., placed 24 in. on centers.

The exterior frame of the building is covered with clapboards laid 5 in. to the weather, while the 12-in. boards below the belt course are laid 8 in. to the weather. The shingles of the roof are laid 4½ in. to the weather.

This Southern farm house for a small family was designed by M. C. Betts, architect, and the plan was prepared in the Office of Public Roads and Rural Engineering of the United States Department of Agriculture.

The word "architect" is said by the London *Builder* to have first occurred in English in a book by John Shute, published in 1563.

Garages in Private Houses

Automobiles at popular prices and the necessity for housing them in the limited space available in more or less congested districts has caused a builder of Brooklyn, N. Y., to make an interesting innovation in connection with a row of ten attached private houses of brick construction which he is erecting. Instead of building the garages in the usual place at the back of the lot he has constructed them in the houses themselves. To enable him to do this, he left, at the rear of the lots, a ten-foot concrete paved driveway from which a driveway somewhat on the style of a railroad siding leads into the basement of each house, where a roomy reinforced concrete fireproofed compartment has been made for the automobile. This arrangement does not interfere with the laundry, heating plant, etc., and has the advantage of leaving a larger area of the yard available for garden purposes.

Production of Abrasives in 1915

The output of natural abrasive materials in 1915 was valued at \$1,662,055, according to figures given out by the United States Geological Survey. Grindstones and like products valued at \$648,479 were produced in Ohio, Michigan and West Virginia. Oilstones, hones, whetstones, scythestones and rubbing stones valued at \$115,175 were produced in Arkansas, Indiana, Ohio, Kentucky and Pennsylvania. Emery to the value of \$31,131 was produced in New York. Tripoli and rotten-stone were produced in Illinois, Missouri, Georgia and Pennsylvania, and diatomaceous earth was produced in California, Connecticut, Maryland, Massachusetts, Nevada, New Hampshire, New York, Oregon, Virginia and Washington. Pumice to the amount of 27,708 short tons, valued at \$63,185, was produced in California, Kansas and Nebraska.

Keep Your Tools Sharp

This is old advice; every woodworker has heard it over and over again—he knows it by rote. But while this may be true, the fact remains that there are certain important lessons which human nature is slow to learn. One of these, and by no means the least, is that chosen for the topic of this article.

Several strong reasons may be urged to show why every self-respecting mechanic, especially the woodworker, should give diligent heed to this simple advice, says a writer in the *Wood-Worker*. First of all, a sharp tool, whether a bench or machine tool, does its work far better than a dull one. Every man who has had experience in handling tools at all knows perfectly well that much more and better work may be turned out by the use of a sharp chisel, a keen-edged plane iron or a well-filed saw than is otherwise possible. A chisel with a razor-like edge will cut its way through a piece of wood almost as easily as through a lump of cheese. In dressing a piece of lumber, a sharp plane does not scrape the surface, leaving it streaky and uneven to the touch (as is usually the case with a dull iron), but leaves the wood clean, smooth and silklike in appearance. If you take a saw in good trim it is simply amazing to see with what ease it eats its

Miscellaneous Constructive Details of a Farm House for a Small Family

way through the lumber. In a word, it is a real pleasure to handle tools that do their work efficiently and well.

When kept in tiptop trim, the teeth of a band saw will eat their way through the wood, even if several inches thick, as easily as if passing through a piece of pasteboard. On the other hand, if the teeth be dull they will just scrape their way through, leaving behind a rough, ragged surface. A dull saw never can produce anything like a clean, smooth cut. To obtain the best results, therefore, in the least amount of time, it always pays to take the best care of one's tools.

The vast majority of mechanics are perfectly familiar with the truth here emphasized, yet every once in a while the expression is heard: "Oh, well, I can't afford the time to sharpen my tools. I must get this job off my hands as quickly as possible." And thus some continue to plod along in a bungling, slipshod fashion, making a botch of their work. Is it any wonder such mechanics are often dubbed "wood butchers?" The name is a most befitting one, because a decent job hardly ever leaves their hands. In the long run it would repay these reckless "butchers" to sacredly devote a share of their time to putting their tools in good cutting order.

Time spent at the grindstone or hone is by no means misspent. As a result their work would prove of far better quality, as well as passing through their hands in less time. In fact, I have found it true in my long years of experience that the difference between a good and poor mechanic is not altogether a matter of superior skill, but is due in part to the better care bestowed by the former on the tools with which he does his work.

The best mechanic I ever knew—a man who could turn out some of the finest work I ever laid eyes upon—was scrupulously careful to keep his cutting tools in first-class condition. He was fairly a crank on this matter; he would neither tolerate a dull tool on his bench, nor allow a fellow-workman to handle either his chisels or gouges. Consequently, when a piece of work was finished and left his bench, it invariably bore the stamp of a masterly hand. All of this goes to prove the importance of the lesson I am striving to impress.

New Building Ordinances of Los Angeles

During the past month or more important changes have been made in the building ordinances of Los Angeles, Cal., the Revision Commission, of which J. J. Backus is president, having recently completed its report after two years of work and filed a report of 70,000 words containing a draft of the proposed ordinance. The latter is intended to codify in comprehensive form and bring up to date the building regulations of the city. No radical departure has been made, as a rule, from the previous ordinance, such changes as are introduced being usually in the direction of economy and saving to the owner, in accordance with the results of experience in other large cities.

An important feature is the new section relating to the construction of hollow tile buildings, the new code permitting the use of hollow terra cotta tile for exterior walls in Class A, B or C buildings outside of certain fire districts, up to 50 ft. or four

stories in height, except that party or bearing division walls may not be of hollow tile. One-story dwellings may be built anywhere with exterior walls of hollow tile, brick or reinforced concrete not less than 4 in. thick, 9 ft. high from floor to plate, with 4 ft. extra for gables; while two-story dwellings may have a 12-in. wall for the first story and a 6-in. wall for the second, of hollow tile, brick or concrete; certain restrictions on the method of construction being included. Hollow cement blocks are permitted in place of hollow tile.

The reinforced concrete section, the first work of the commission, was passed twenty months ago, and has effected a great saving of materials through the raising of the allowable stress on concrete, etc. A comprehensive ordinance relating to fire escapes, standpipes and automatic sprinklers, recommended by the commission earlier in its work, has given satisfaction, and both are included in the new code.

The structural steel and structural engineering provisions have been considerably elaborated and will be of great aid to architects and engineers. One important change is the requirement of fire-proof sash and window frames within certain fire districts, which does away with fire shutters. Requirements for boiler room construction have been made more exacting, and general stairway requirements enlarged upon.

With the report a number of recommendations were submitted, to be codified later if approved by the Council.

New York Society of Architects

The New York Society of Architects held its annual convention on May 16 at the Engineering Societies Building in West Thirty-ninth Street, New York City, when officers for the ensuing year were elected as follows:

<i>President</i>	James Riley Gordon
<i>First Vice-Pres.</i>	Adam E. Fisher
<i>Second Vice-Pres.</i>	Edward W. Loth
<i>Secretary</i>	William T. Towner
<i>Treasurer</i>	Oscar Lowinson
<i>Financial Secy.</i>	Ed. Wehrlein

The present membership is 340, of which nearly 200 were elected during the past year.

Building Operations in Chicago

The volume of building operations for which permits have been issued in Chicago as shown by the report of the city building department for the month of May is 73.45 per cent greater than the same month a year ago. There were 1207 permits issued, with an estimated cost of \$13,707,100, as compared with 786 permits estimated to cost \$7,902,900 in May, 1915. It is the largest May total in the history of the city.

For the five months of the year there has been an increase of 67 per cent, a surprising showing in view of the fact that the totals for 1915 were, with one exception, the largest ever enjoyed by the city.

The interesting as well as disturbing feature of the present year's operations is the fact that the bulk of the permits taken out are for apartment buildings, and furnishes conclusive evidence of the overbuilding being done in this field.

Notable Recent Court Decisions

Determinations as to Architects' and Contractors' Right to Compensation—Time for Filing Lien Statement

BY A. L. H. STREET

AMONG the decisions lately announced by courts of last resort, I find several which hold peculiar interest for architects and builders on account of the common-fact situations presented in the cases adjudicated.

When an owner unjustifiably breaks his part of a building contract by preventing the contracting builder from completing performance, the contractor, if he remains ready and able to perform, may recover damages measured by the profits which he would have been able to have earned if he had been permitted to carry out the contract. So holds the California Supreme Court in the case of *Connell vs. Higgins*. The damages are to be computed according to the excess of the unpaid part of the contract price above the reasonable cost of completing that part of the work which he was prevented from performing.

Under a mechanic's lien statute, requiring a general contractor to file his notice of lien within sixty days following "completion" of the work, where work on a building is abandoned by mutual consent, notice of lien is filed in time by filing within sixty days after the cessation of work is agreed upon, according to the holding of the District Court of Appeal for California, in the case of *Trimlett vs. De Coursey*.

Skill Required of Architects

Rights of an architect to recover for professional services, as against objection by the employing owner that the services were negligently performed, were considered by the Supreme Court of Georgia in the case of *Happ vs. Block*. The court holds that, by accepting employment, an architect impliedly represents to his employer that he possesses sufficient taste, skill and ability to enable him to perform the required services at least ordinarily and reasonably well.

Plaintiff contracted with defendants to prepare plans and specifications for the erection of a four-story building, and to supervise its construction. Part of the agreed lump sum compensation for the work was paid in advance, and it was stipulated that the remainder would be paid on completion of the structure. After completion of the building, defendants accepted it and placed their tenant in possession, but, on it being subsequently ascertained that the basement was insufficient to resist seepage of water, defendants refused to pay the last installment due plaintiff. To his suit, brought to enforce payment, defendants interposed a plea that the defective condition of the basement was

due to plaintiff's negligence and unskillfulness in preparing the plans and in supervising the construction, and further pleaded extra expense in remedying the defects. Under these facts, it was held by the Supreme Court that, defendants having accepted the building, plaintiff was entitled to sue to recover the balance of the unpaid compensation, subject to defendants' right to offset any damages resulting to them as a direct consequence of any negligence or unskillfulness on plaintiff's part, within the general rule above stated.

Effect of Trade Customs

It has become a well-settled rule of law, applicable to building contracts as well as agreements in general, that they will be interpreted in the light of general customs known to the parties, except so far as the express provisions of a contract are inconsistent with a custom invoked.

This rule is recognized in the case of *New Jersey Terra Cotta Company vs. Traves*, decided by the Michigan Supreme Court recently. In this suit the company was awarded recovery on defendant's bond as a building contractor for a balance due for architectural terra cotta sold him. The material proved to be satisfactory to the architect, and no objection was made to the manner in which it was used, but defendant counterclaimed damages on the ground that the material did not comply with the plans and specifications, with reference to which it was furnished. The terra cotta was used chiefly for cornice work, and it is claimed that the plans showed the size and shape of the terra cotta pieces, indicating a comparatively small number of large blocks, which could easily and inexpensively be placed in the walls, but that the material furnished by the company consisted of small blocks of such shape and number as to require extra labor in setting. Under these circumstances, the Supreme Court holds that it was not improper on the trial of the case to receive testimony of architects to show that it was a general custom in connection with contracts of this kind to send the plans to the terra cotta company, or other special material man, and have them adapt their construction to the architect's design, as shown by his plans, they furnishing the detail drawings and working plans, and that such course was followed in this case; that details and working plans were prepared by plaintiff terra cotta company, submitted to the architect, changed in some particulars, according to his directions, and finally approved by him before the terra cotta was made and shipped.

The architect's general plans for the building indicated, for use in the terra cotta cornice, longer and larger blocks than those actually used in the construction, showing them laid upon the wall so

as to project over both sides. But the architect testified that those places did not particularly show the construction—"more the design and size"—and that the indication of large blocks extending the full width was an error in drafting, as terra cotta work was not generally constructed in that way. In the construction, under the specific plans furnished by the company, the outward design and size of the cornice was the same as shown by the general plan, but smaller blocks were used, which did not project into the wall its full width, being braced and held by metal supports. The court concluded:

"Whether there was a custom, its nature and Traves' knowledge of it, and whether the parties contracted with reference to it, were questions opened to inquiry by the conflicting testimony, which fairly raised an issue for the jury. This was not precluded by the stipulation relative to plans, and the general plans furnished, for specifications also were equally binding, and details to be approved by the architect were required by the specifications. This is in harmony with the custom sought to be proved in explanation of the contract, rather than in exclusion of it."

Performance by Contractor

In the case of Giberson vs. Fink, the California District Court of Appeal decided several important rules, which apply to nearly every building contract. As to time of performance, it is held that if the agreement specifies no time the work must be completed within a reasonable time, and what is a reasonable time depends upon the circumstances under which the work is done in a particular instance. When a time is set for completing a five-room dwelling house, a delay of seven days in finishing the work will not be regarded as unreasonable. "Ordinarily, a provision in a building contract specifying a definite time within which the structure shall be completed is to be construed with reference to the building proper, and that it shall be at the end of such time in such condition as to be ready for occupancy," unless there is some clause in the contract excluding such interpretation. So the court holds that a slight delay in finishing a sidewalk included in a building contract is not a substantial breach on the builder's part where the building proper is ready for occupancy in due time.

As to deviations from the plans and specifications, the court decides that an owner estops himself to complain afterward of a change in location of the building on its lot, or the use of a different kind of material for the foundation from that called for by the contract, where he knows of the departures from the agreement at the time they are being made, and makes no complaint then. And the court further recognizes the just rule that the building cannot be rejected by the owner merely because of some slight omission, such as failure to construct cupboards in a kitchen, where they can be supplied readily without material alteration of the building. It is to be inferred, however, that the owner could demand a deduction from the agreed price to cover such omissions.

The Building Material Dealers' Credit Association is the name of an organization just incorporated at Dayton, Ohio, the purpose of which is stated to be "the exchange of ideas and the general benefit and protection that such bodies usually afford their members in the legitimate conduct of their business."

Primitive Doors and Windows in South Africa

A correspondent in South Africa writing to a recent issue of the *Illustrated Carpenter and Builder* of London, comments as follows on the subject indicated by the above title:

"Window blinds are comparatively unknown in the small villages in the Transvaal and Orange River Colony. This is due to the fact that the windows in the houses vary so much in size and shape that it would not pay to stock any average-sized blinds. Substitutes are used, very often of a very primitive character. In some instances this substitute takes the form of a blanket that is hung over the window. When the sun shifts round to the other side of the house in the afternoon the blanket is transferred accordingly. Amongst the farmers blinds are unknown, as are windows. There are openings, certainly, that can be closed up by closing the shutters, but there is no glass. The shutters are roughly made, and by no means air-tight, but as the Boer moves from one room to another, according to how the wind blows, he does not suffer from draughts.

"The making of these shutters helped the wheelwright and blacksmith, which callings, represented in a single person, were to be found in every agricultural center, to turn to advantage many an hour that would otherwise have been passed in idleness. As a general thing the 'guest room' was the only chamber to be first adorned with these shutters, the rest of the rooms still having to put up with the home-made articles, but by degrees the other rooms rose to the same dignity. The painter sometimes gets a night's shake-down and a shilling to help him on his road by giving the shutters a coat. Failing this, there is always something else for him to do that will tide him over the hours of darkness, for the Boer is fond of vivid coloring.

"The stranger who arrives at a Boer homestead and finds the shutters all up knows at once that there is trouble in the house and passes on. This trouble may not be of a serious nature; it may be that the *vrouw* has burned her hands in baking the bread, or the 'old man,' as the head of every Boer home is called, has a touch of the 'shakes,' a mysterious disease that has nothing to do with malaria, but, whatever the cause, the meaning is plain, and he who should ignore it would have but a chilly reception.

"The door of a Boer homestead is made in two halves. The origin of this is that when the Boers first came into the Transvaal they were subject to more or less constant attacks from the Kaffirs, and the half door was handy. The householder could rest his rifle on it and obtain fairly good cover whilst sniping at the enemy. Old customs live long, and the door 'cut in halves' is still to be met with on almost every farmhouse."

Aroba, a Cocobola Substitute

Aroba is the local and trade name of a West Indian timber which has recently been introduced into the American markets. It is said that the aroba tree occurs in great abundance in Cuba, Jamaica, Trinidad and parts of the Spanish Main and that the wood can easily be supplied in very large quantities. While the wood is employed to some extent in general carpentry work in Cuba and Jamaica, its use is for fence and telegraph posts.

Problems in Geometrical Drawing

Something the Progressive Carpenter and Builder
Will Find Useful in Connection with Their Work

By W. S. WILKIN

WHAT here follows relates to a few problems in geometrical drawing together with polygon scales and a table of lengths per foot run for a rise of from 1 in. to 25 in., all of which I hope may prove interesting to readers of the paper. The sketches show how to use the tables in laying out work with the steel square. Fig. 1 shows an equilateral triangle, which may be laid out as follows. Let ab represent one side. Now with b as center and ab as radius, strike an arc at c ; then with the same radius and a as center, strike another arc intersecting at c . Draw the lines cb and ca and the result is the triangle.

Fig. 2 shows how to draw one line parallel to an-

other. Let ab represent the line, then with any radius and a center anywhere on the line ab as at d , draw the arc as shown; then with the same radius, and any point on the line ab and c as center, draw another arc. Now draw the line ef tangent to the arcs as shown and it will be parallel to ab . If the lines must be a given distance apart take that distance as a radius when drawing the arcs.

Fig. 3 shows a very simple problem, but one which comes in handy very often. Suppose we wish to divide the line ab into fifteen equal spaces without the use of the dividers. Draw the line bc perpendicular to ab , then take the rule or a rod 15 ft. long if the work is that large, place one end at a and bring it around until the fifteen-mark comes at c .

Mark every inch or every two inches or every foot, according to whatever you are using, as 1, 2, 3, etc. Then draw the perpendicular lines from each of these points. As a result the line ab will be divided as shown at 1', 2', 3', etc. In this way the divisions on the line ac may be taken from the line ab or whichever the case may be.

In Fig. 4 is represented a little problem in proportion done with the steel square. At A we have a beam or lever, as the case may be, with three holes in it as shown. Suppose we wish to make another one and to make the long end 14 in. as shown at B instead of $20\frac{1}{2}$ in. as at A . Suppose also we wish to shorten the short end in proportion so as to have

Problems in Geometrical Drawing—Interesting Solutions for the Builder

other. Let ab represent the line, then with any radius and a center anywhere on the line ab as at d , draw the arc as shown; then with the same radius, and any point on the line ab and c as center, draw another arc. Now draw the line ef tangent to the arcs as shown and it will be parallel to ab . If the lines must be a given distance apart take that distance as a radius when drawing the arcs.

Fig. 3 shows a very simple problem, but one which comes in handy very often. Suppose we wish to divide the line ab into fifteen equal spaces without the use of the dividers. Draw the line bc perpendicular to ab , then take the rule or a rod 15 ft. long if the work is that large, place one end at a and bring it around until the fifteen-mark comes at c .

the same leverage. In Fig. 5 we show how to do it with the steel square.

Take a board as a, b, c, d , and have the edge dc straight. Draw a line square across it as ef . Now measure 14 in. from e to g , which represents the 14-in. end of the lever B of Fig. 4. Next take $20\frac{1}{2}$ in. on the blade of the square which represents the long end of the lever a of Fig. 4 and $13\frac{1}{4}$ in. on the tongue which represents the short end of the lever a , and apply the square as shown in Fig. 5 so that the blade crosses the edge of the board at the 14-in. mark. Now mark the point where the blade crosses the line ef which is about 9 in. from e and represents the short end of the lever B of Fig. 4.

In order that the reader may more clearly grasp

the principle involved, I have measured on the edge of the board $20\frac{1}{2}$ in. as shown, and on the line $e f$ $13\frac{1}{4}$ in. from e , which represents both ends of the lever A . It will be seen that a line drawn from one of these points to the other is parallel with the blade of the square. It will be seen that:

$$e 20\frac{1}{2} : e 14 :: e 13\frac{1}{4} : e g$$

This method is accurate, but, of course, a small drawing is not as accurate as it might be. It should be a little over 9 in.

Suppose now we wish to make another lever 17 in. between two outside holes, as shown at C of Fig. 4, and wish to make it in proportion to the lever A . We must locate the center hole, and to do this make $a b$ 17 in. as in Fig. 6. Next draw $b c$ perpendicular to $a b$. Take a as center and $33\frac{3}{4}$ in. as radius. This is the length of the lever A . Mark at c . Draw a line from a to c . Mark at d $20\frac{1}{2}$ in. from a ; then from d to c will be $13\frac{1}{4}$ in. Draw the line $d e$ parallel to $c b$ and e will be the point for the center hole, which makes the long end about $10\frac{3}{8}$ in. and the short end about $6\frac{5}{8}$, as at C Fig. 4.

In Fig. 7 is indicated a good method of drawing an egg-shaped oval. With o as center and radius

put on by the user with the base and perpendicular—blade and tongue—marked off in inches, etc. The diagonal side is made either by placing little metal attachments, commonly called stair gages, on the blade and tongue, or by using a straight piece called fence, and hereafter I shall speak of it as a fence. By shifting the fence from one position to another on the blade and tongue we can make any right triangle imaginable, but we must know what figures to use in order to obtain the angle desired.

Herewith are presented three tables which I made several years ago, and have found them very handy at times. Tables No. 1 and No. 2 relate to polygon scales, while Table No. 3 gives the length per foot run for a rise from 1 in. to 25 in.

Table No. 1 is a polygon scale for butt joint for regular polygons from three to twelve sides, and according to it take 12 in. on the tongue and the blade will give the cut for five sides. The tongue gives the cut for all the rest. The columns marked "Sides" give the number of sides in the polygon. The next column marked "Central Angle" gives the number of degrees contained in each of the angles formed by drawing lines from the corners of the polygon to the center, as in Fig. 11. This diagram shows one-half of a pentagon, or five-sided figure. The central angle is 72 deg., which is found by dividing 360, the number of degrees in a circle, by the number of sides in the polygon.

In the third column headed "Blade" will be found the number to take on the blade, with 12 on the

Problems in Geometrical Drawing—Various Tables of Special Value to the Builder

equal to half the width of the required oval, draw the circle $a c b a$. Erect the perpendicular $o c$ and draw the lines $a c e$ and $b c d$. Now with b as center and $b a$ as radius, draw the arc $a d$. Next with a as center and the same radius draw the arc $e b$. Again with c as center and $c d$ as radius draw the arc $d e$ which completes the oval.

In order to fully understand the steel square it is necessary to know something about geometry and geometrical drawing, and in this and another article I have, I think, explained enough to give the reader not already familiar with it a fair idea of lines, angles, etc.

The steel square is nothing more or less than a right triangle with the diagonal side left off to be

tongue to give the angle for the butt joint, as shown in Fig. 8. The heel of the square must point toward the outside of the polygon for all except the triangle because for the sides of a triangle forming an acute angle the heel must be turned in.

Fig. 8 represents a hexagon which has six sides. Referring to Table No. 1 we find that for six sides we take 20 25/32 on the blade and 12 on the tongue and the tongue gives the cut for the butt joint, as shown in the drawing.

Now suppose we desire to cut pieces for a pentagon which has five sides, as in Fig. 11. In Table No. 1 we see that for five sides it gives 3 29/32 for the blade; taking this on the blade and 12 on the tongue, the table shows the blade gives the cut for

five sides, as shown at A in Fig. 11. If we wanted to cut on the tongue for five sides we should take about 37 on the blade, and as the blade is only 25 in. long I take 3 29/32 on the blade and cut by it.

It will be seen in Fig. 11, at B, that by taking the same figures as for the butt joint the blade also gives the central angle of 72 deg.; also it will be seen at A in Fig. 10 that by taking the same figures on the square as we used in Fig. 8, the tongue gives the central angle as if we were making a hexagon floor and the joist b ran all the way through. The tongue would give the cut on the joist a to fit against b.

Referring now to Table No. 2 it says take 12 on the tongue and the blade gives the cut for outside, or to miter plate, while the tongue gives the cut for inside or to miter rafter, except per foot run must be taken on the tongue instead of 12. The first column gives the number of sides; the second column, B angle, gives the angle a blade makes with a line or the edge of a board; the third column, T-angle, is the angle between the tongue and the edge of the board, while the fourth column gives the figures to take on the blade for the different polygons.

Suppose it is desired to miter a hexagon. We look in Table No. 2 for six sides and we find 6 15/16

Referring now to Fig. 12 we have 12 on the tongue and 10 1/16 on the blade—the angle for nine sides, according to Table No. 1. The tongue gives an angle of 40 deg., which is the central angle, also the outside angle. The blade gives an angle of 50 deg. between the blade and the horizontal line. The tongue gives an angle of 50 deg. between it and the perpendicular line, while the blade gives an angle of 40 deg. between it and the perpendicular. The four angles together make 180 deg., or two right angles.

This is the case no matter how we apply the square, as will be seen in Fig. 13. We have 12 on the tongue and 6 15/16 on the blade, which gives the butt joint for twelve sides and the miter joint for six sides. The tongue gives an angle of 30 deg. and 60 deg., and the blade gives an angle of 60 deg. and 30 deg.; also the blade makes an angle of 120 deg. from the line on the right as shown, and the tongue makes an angle of 150 deg. from the horizontal line on the left.

The fractions given in all three of the tables are intended to be the nearest thirty-second of an inch and while they may not be perfect they are near enough for most practical purposes and by the use of the tables many angles may be found.

Fig. 6—Another Phase of the Problem in Fig. 4

Fig. 7—Drawing an Egg-Shaped Oval

Fig. 8—A Hexagon

Problems in Geometrical Drawing—Some Solutions of Special Value to the Builder

for the blade and 12 for the tongue: the blade gives the cut as shown in Fig. 9. If we want to put in short floor joists, as at B, Fig. 10, we take the same figures as in Fig. 9, but according to Table No. 2 we cut by the tongue instead of by the blade.

To miter five sides Table No. 2 gives 8 23/32 on the blade and 12 on the tongue. The blade gives the cut, as shown at C in Fig. 11.

The miter cut for an octagon is 4 21/32 on the blade and 12 on the tongue; the B-angle, that is, the angle between the blade and the line on which the square is applied is 67 deg. 30 sec., as shown in Fig. 14, and the T-angle, that is, the angle between the tongue and the line on which the square is applied has 22 deg. 30 sec., as shown; now

$$67^{\circ} 30' + 22^{\circ} 30' = 90^{\circ}$$

or one right angle, and it will be seen all through Table No. 2 that B-angle + T-angle = 90 deg.

In Table No. 1 the central angle is the same as the outside angle, as will be seen at A and B in Figs. 11 and 8, and the angle at A in Fig. 10.

Table No. 3 is very handy for connecting inclined work such as rafters, hoppers, etc. The first column gives the rise per foot run; the next column the length in inches and decimals; the third column the equivalents of the decimals to the nearest thirty-second, and the fourth column gives the gain.

For a rise of 9 in. to the foot the length is 15 in. and the gain is 3 in.; that is, the slope length is 3 in. longer than the run. For a rise of 12 in. to the foot the length is 16.9706 in., or 16 31/32 in., often called 17 in.

If B, Fig. 10, was a rafter with a rise of say 10 in. to the foot and it was to be cut against the hip, Table No. 2 says take the length per foot run on the tongue instead of 12; so we look in Table No. 3 and we find that for 10-in. rise the length is 15 5/8 in., so we take this figure on the tongue and 6 15/16 on the blade and apply, as in Fig. 10 at B.

We cannot always use these tables, for occasionally the rise per foot run is not in even inches and the corner of a building is often an odd angle.

We must then make a drawing of the corner on a board or elsewhere and know how to use the square accordingly.

If the run and rise come out in even numbers Table No. 3 can be used to find the length of the rafters. Suppose, for example, we have a run of 10 ft. and a rise of 8 in. per foot run, then to get the length of rafter we look in the length column in Table No. 3 and find 14.4222 in. as the length per foot run. For a 10-ft. run we have therefore:

$$14.4222 \times 10 = 144.222 \text{ in.}$$

the length of rafter, or 12 ft. 7/32 in.

Drawings Are Not Architecture

We are told on excellent authority that a written play is not a play at all. It is only a book of directions for bringing one into existence. Similarly a set of plans does not constitute an architect's out-

and cabinetmakers, carvers and decorators, workmen of all kinds—whose only aim in life is apparently to deviate from the plans as much as possible. These mechanics can so mutilate and distort a design that the result may be very different from the architect's conception, which remains a dream that the public will never know.

Annual Waste of Wood

According to the Forest Service of the U. S. Department of Agriculture the output of waste in the form of sawdust, shavings, slabs and other wood refuse of the more than 48,000 saw mills in the United States is estimated at 36,000,000 cords per year. Perhaps one-half of this so-called waste product is not, strictly speaking, wasted, but serves a useful purpose as fuel under the boilers. Much of the remaining 18,000,000 cords not only serves no useful purpose, but in most cases is a source of

Problems in Geometrical Drawing—Solutions of Special Value to the Builder

put any more than a copy of his specifications. Like a play, the plans are merely the directions for producing something. A drawing, be it ever so attractive and convincing, is only a promissory note which binds its maker to deliver in the concrete what is stated on its paper face, said Arnold W. Brunner, in an address before the National Institute of Arts and Letters. Sometimes it may be well to pause and consider if the author has sufficient funds in his mental bank to make good.

Like the dramatist, certain forces stand between the architect and his audience. I am told that dramatic authors often find difficulty in maintaining their conception and persuading managers, producers and actors to follow their ideas and faithfully interpret them. The architect has his interpreters, too. Masons and carpenters, plasterers

inconvenience and danger, at the same time costing the mill time and money.

Saw mill waste is disposed of in various ways, and at present the Forest Service is working on the problem of the utilization of the waste in such a way that it will pay for its disposition.

Galvanized corrugated iron in sheets is much used for roofing and as a covering for sides of buildings, walls of inclosures, partitions, etc., in the larger towns of the Dominican Republic.

The fossil coral of the Fiji Islands is said to be the best building stone in the world. When first cut it is almost as soft as cheese, but it solidifies in the air until it is as hard as granite.

Hints for Removing Stains from Wood

How Small Articles May Be Bleached—Directions for Taking Out Weather-Surface Stains

TO bleach stains out of wood a number of points must be observed to make a successful job and to prevent the after-effects from the bleaching materials and chemicals. Soft wood or close-grained woods, such as pine, etc., require bleaching at times as well as hard woods, and the treatment of either of those woods is almost similar. The stains usually required to be bleached out of wood are as follows: Weather or water stains, alkali stains, color stains, particularly aniline stains, dog and cat urine stains, iron rust stains, etc. The bleaching out of rust stains and dog's urine has been difficult and has so far withstood all usually employed methods, but, nevertheless, it is an easy matter.

Hard Woods Difficult to Bleach

The hard woods which are easily affected by the weather by alkalines, etc., and which are difficult to bleach, says a writer in the *Painters' Magazine*, include all woods containing tannic acid in a larger or lesser degree, and include oak, mahogany, cypress, birch, cherry, chestnut, walnut, ash, etc. All sappy or white woods are more easily bleached, such as pine, spruce, hemlock, whitewood, poplar, maple, bass, gum, and similar woods.

As mostly all of the wood to be bleached has some kind of a finish it is of importance to have the finish thoroughly removed before starting the bleaching process. In the case of using a remover containing oil or wax, a final cleaning must be done with soda water or alcohol, to remove all traces of the wax and to allow the bleaching material to affect the wood and to penetrate. As all methods for bleaching wood are based on water-soluble chemicals, it is impossible to avoid the sponging up of the wood or the raising of the fiber of the wood.

How to Bleach Small Articles

To bleach small articles, it is advisable to have a wooden tank made of sufficient size to immerse the articles to be bleached, which also would make a more perfect job and save a good deal of the bleaching material, although this is very low priced. The tank for this purpose must be properly joined. No nails or other iron parts should be used on it, and the joints should be bound with white-lead putty or casein. A porcelain-lined metal tank would also answer the purpose, or a rubber-coated tank would be advisable.

For ordinary bleaching of surface-weather stains the following solution is sufficient: One pound oxalic acid dissolved in one to one and one-half gallons of hot water. For a more deep-rooted stain an addition of strong white vinegar, or still better, acetic acid, is required, and the bleaching liquid should be applied as hot as possible, repeating the application of same until sure that the bleach has gone as deep

into the wood as the stain itself. After bleaching, it is required to thoroughly wash the surface, and an extra sponging off with vinegar is essential.

To bleach aniline stains apply a strong solution of chloride of lime and after a while wash off with clean water, after which apply the oxalic acid method as above given. If the stains do not yield to this treatment, apply a solution of tartaric acid, and treat afterward as above.

Removing Rust Stains

For rust stains the same method is to be used, but in bad cases, instead of using tartaric acid, diluted hydrochloric acid, or a solution of citric acid will do the trick. The chloride of lime method is to be used for dog or cat urine stains. In all cases the oxalic treatment afterward is required.

The methods, therefore, of removing such stains are simple enough, but great care must be observed in the handling of those chemicals, as all of them are more or less dangerously poisonous.

In refinishing the wood, the following is to be strictly observed to make a perfect job, and particularly if the wood has to be filled or stained to avoid a spotted or clouded appearance of the finish. After thoroughly cleaning and drying of the bleached surface, do not sandpaper, but apply a thin coat of shellac which must be pure, greatly reduced with alcohol, about one-half the strength of the regular article used for finishing. Allow twenty-four hours, or as long as possible, for the shellac to dry, after which sandpaper, and only then start the staining, filling or whatever finish is required. The shellac, be it ever so much reduced, will harden the raised fibers of the wood, and by sandpapering (or using steel wool) they will cut the fibers off short, making a perfectly smooth surface; furthermore, the softer parts of the wood will absorb the shellac to some extent, preventing the stain or colored filler to accumulate in those parts more than on other sections of the surface, and will give a more uniform finish. This is particularly important and apparent where cross-cuts of the wood are intended to show a uniform finish or color with the balance of the job. This treatment with shellac is intended for exterior as well as interior work, and is in no way detrimental for the best exterior work, providing the guaranteed pure shellac is used.

Aniline Stains

If aniline stains are not intended to be removed, but it is wished to prevent them from striking through subsequent coating, particularly enamel or paint, etc., the following method is suggested for making stains permanent: Take 1 lb. of green copperas (ferro-sulphide) and dissolve in 1 or 2 gal. of hot water. Add to it one-half the quantity of alum and apply one to two coats of this over the surface.

A Two-Family House of Hollow Tile

Each Apartment Designed to Secure Utmost Privacy
—Stucco Finish—Construction Partially Fireproof

THE interest which builders and architects evince in the subject of the Two-Family House has caused us to present a dwelling of this type as the subject of our colored supplemental plate. The house has been designed for a lot with a frontage of 40 ft. and with the idea in view of compactness in plan, comfort in size and number of rooms, privacy, partial fireproof construction, etc.

According to the specifications of the architect, the foundation walls are to be of concrete, 10 in. thick, supported on footings of the same thickness and extending 6 in. beyond each side of the walls above. All concrete to be mixed in the proportions of one cement, three sand and five of broken stones.

The Framing Timbers

All framing timbers are to be of spruce with girders 4 x 8 in., plates 4 x 4 in., and the first and second floor beams 2 x 10 in., placed 16 in. on centers and braced with 2 x 2-in. cross bridging spaced 5 ft. on centers. The beams will be set on terra cotta slabs 1 in. thick, which are to serve as bearing plates. These slabs are also to be used for working up levels and story heights where the blocks do not work out correctly. All openings are to be spanned by lintels, using special lintel blocks reinforced with bars and concrete. Concrete or hollow tile blocks will be used for the construction of porch and entry columns. The second floor ceiling beams and roof rafters are to be 2 x 8, all placed 20 in. on centers. The interior partitions are to be built up of 2 x 4 studding covered with wood lath and the studs are to be doubled at all openings.

The Exterior Walls

All exterior walls are to be of terra cotta hollow tile blocks, 8 x 12 x 12 in. set in a mortar consisting of one part cement to three of sand, with not more than 10 per cent of the mass by volume of well slacked lime. The tile is to be thoroughly wet before applying the stucco, which is to be two-coat work throughout. The scratch coat is to consist of one part Portland cement, three parts sand and not more than 10 per cent lime putty. It shall be at least a half-inch thick and applied under pressure. The finish coat shall consist of one part cement, two parts sand and shall be 1¼ in. thick.

The roof plates are to be bolted to the hollow tile walls every five feet. The roof is to be covered with sheathing boards over which is to be placed a layer of tarred roofing felt, upon which, in the sloping parts, is to be laid dark green slate exposed 5½ in. to the weather, and in the rear portion tin is to be used, the tin to have a good coat of metal paint before being laid. Leaders for front gutter to be carried down in the hollow tile.

The chimney, which takes care of both the heating systems and the fireplaces in the living rooms, is to be built of brick and have four flues lined with vitrified flue lining.

The exterior woodwork is to be of clear white pine, and all interior trim may be of cypress, pine or birch.

Arrangement of Rooms

An inspection of the floor plans shows that special attention has been given to the privacy of each apartment; each family having its own separate entrance, rear kitchen, separate cellar and yard with entrances thereto, and separate furnace.

Each apartment is entered through a reception room which leads into a good sized living room, the main feature of which is a fireplace. The reception room also opens through French casement doors onto a private porch. The living room is separated from the dining room by a cased opening. The kitchen is reached by way of the pantry, and also from the small hall out of which opens the bath room and sleeping rooms. The refrigerator space is conveniently placed and a private stairway leads to the cellar. A sleeping porch can be reached through French casements from either the kitchen or rear bed room.

The cellar extends under the entire building and is to have a 4-in. concrete floor with a smooth cement finish.

All rooms are to be plastered, the plaster being applied direct to the hollow tile walls as the blocks are arranged to receive it. The living room is to have a sand finish.

All floors are to be brought to a smooth finish, filled and varnished. The living and dining rooms to receive an additional coat of wax.

The Interior Trim

The interior trim is to be stained and finished flat. The living and dining room walls and ceiling are to be tinted, the bed room walls papered and the kitchen and pantry trim to be painted three coats of white flat paint.

All sheet metal work is to be painted on both sides before it is laid and all leaders are to be of galvanized iron.

A good system of plumbing is to be installed with simple fixtures, using a galvanized iron enameled sink and a three-part wash tray of soapstone or enameled iron. All the plumbing is to be exposed, the rough pipes being painted with enamel paint.

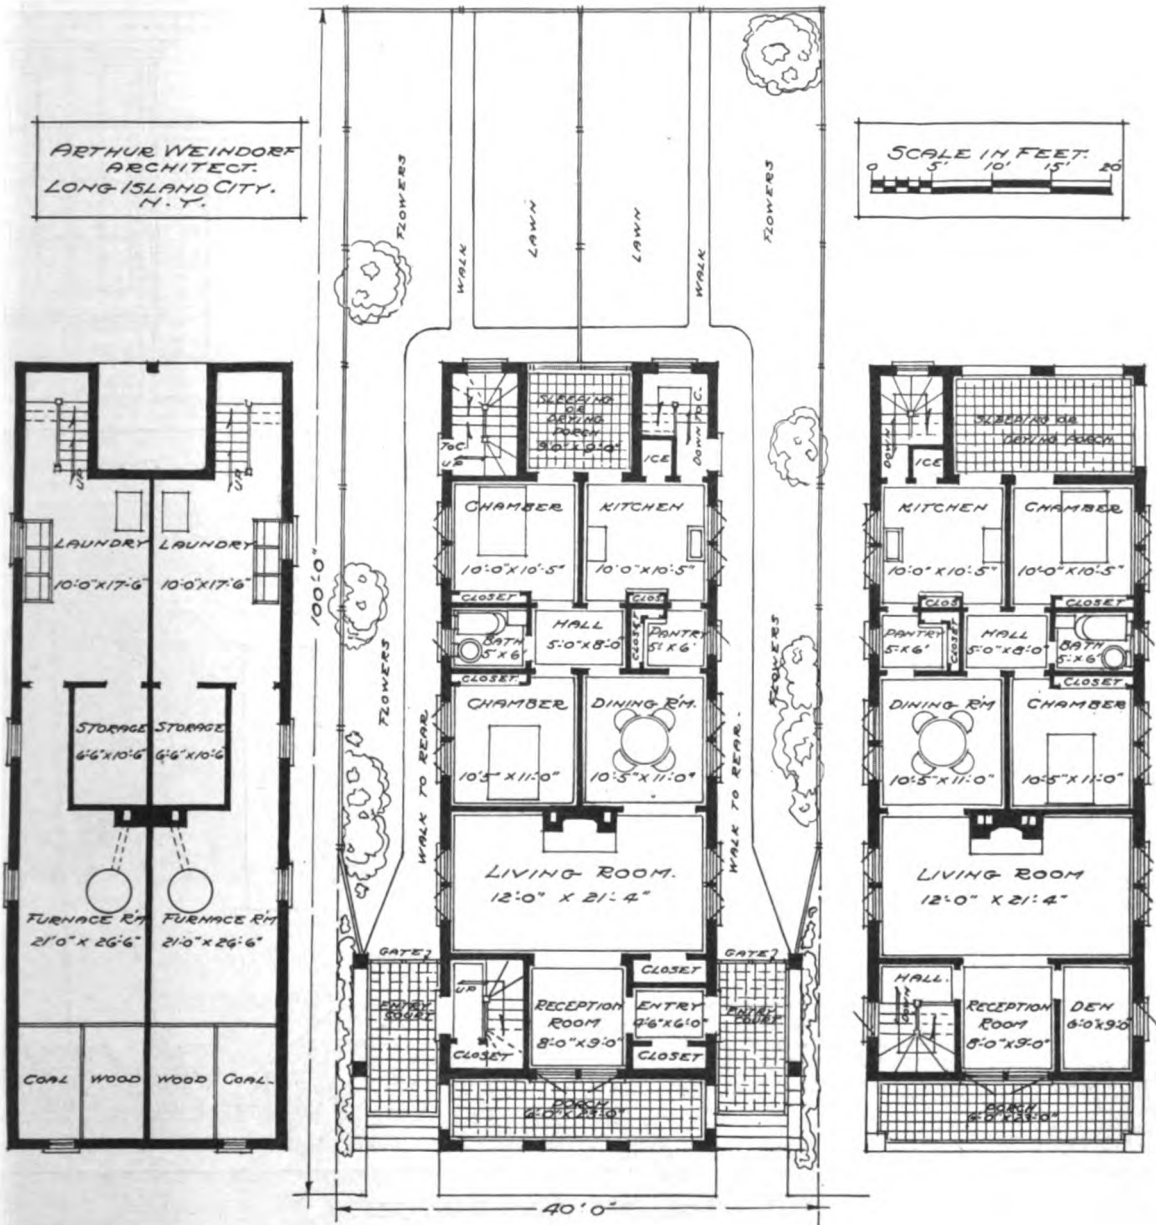

The bathroom is to contain an iron enameled bath tub, the water closet to have a china bowl with hardwood seat and high tank, and the washstand a china bowl and marble top. All exposed pipes are to have a nickel-plated finish. Fixtures are to be

REAR ELEVATION.

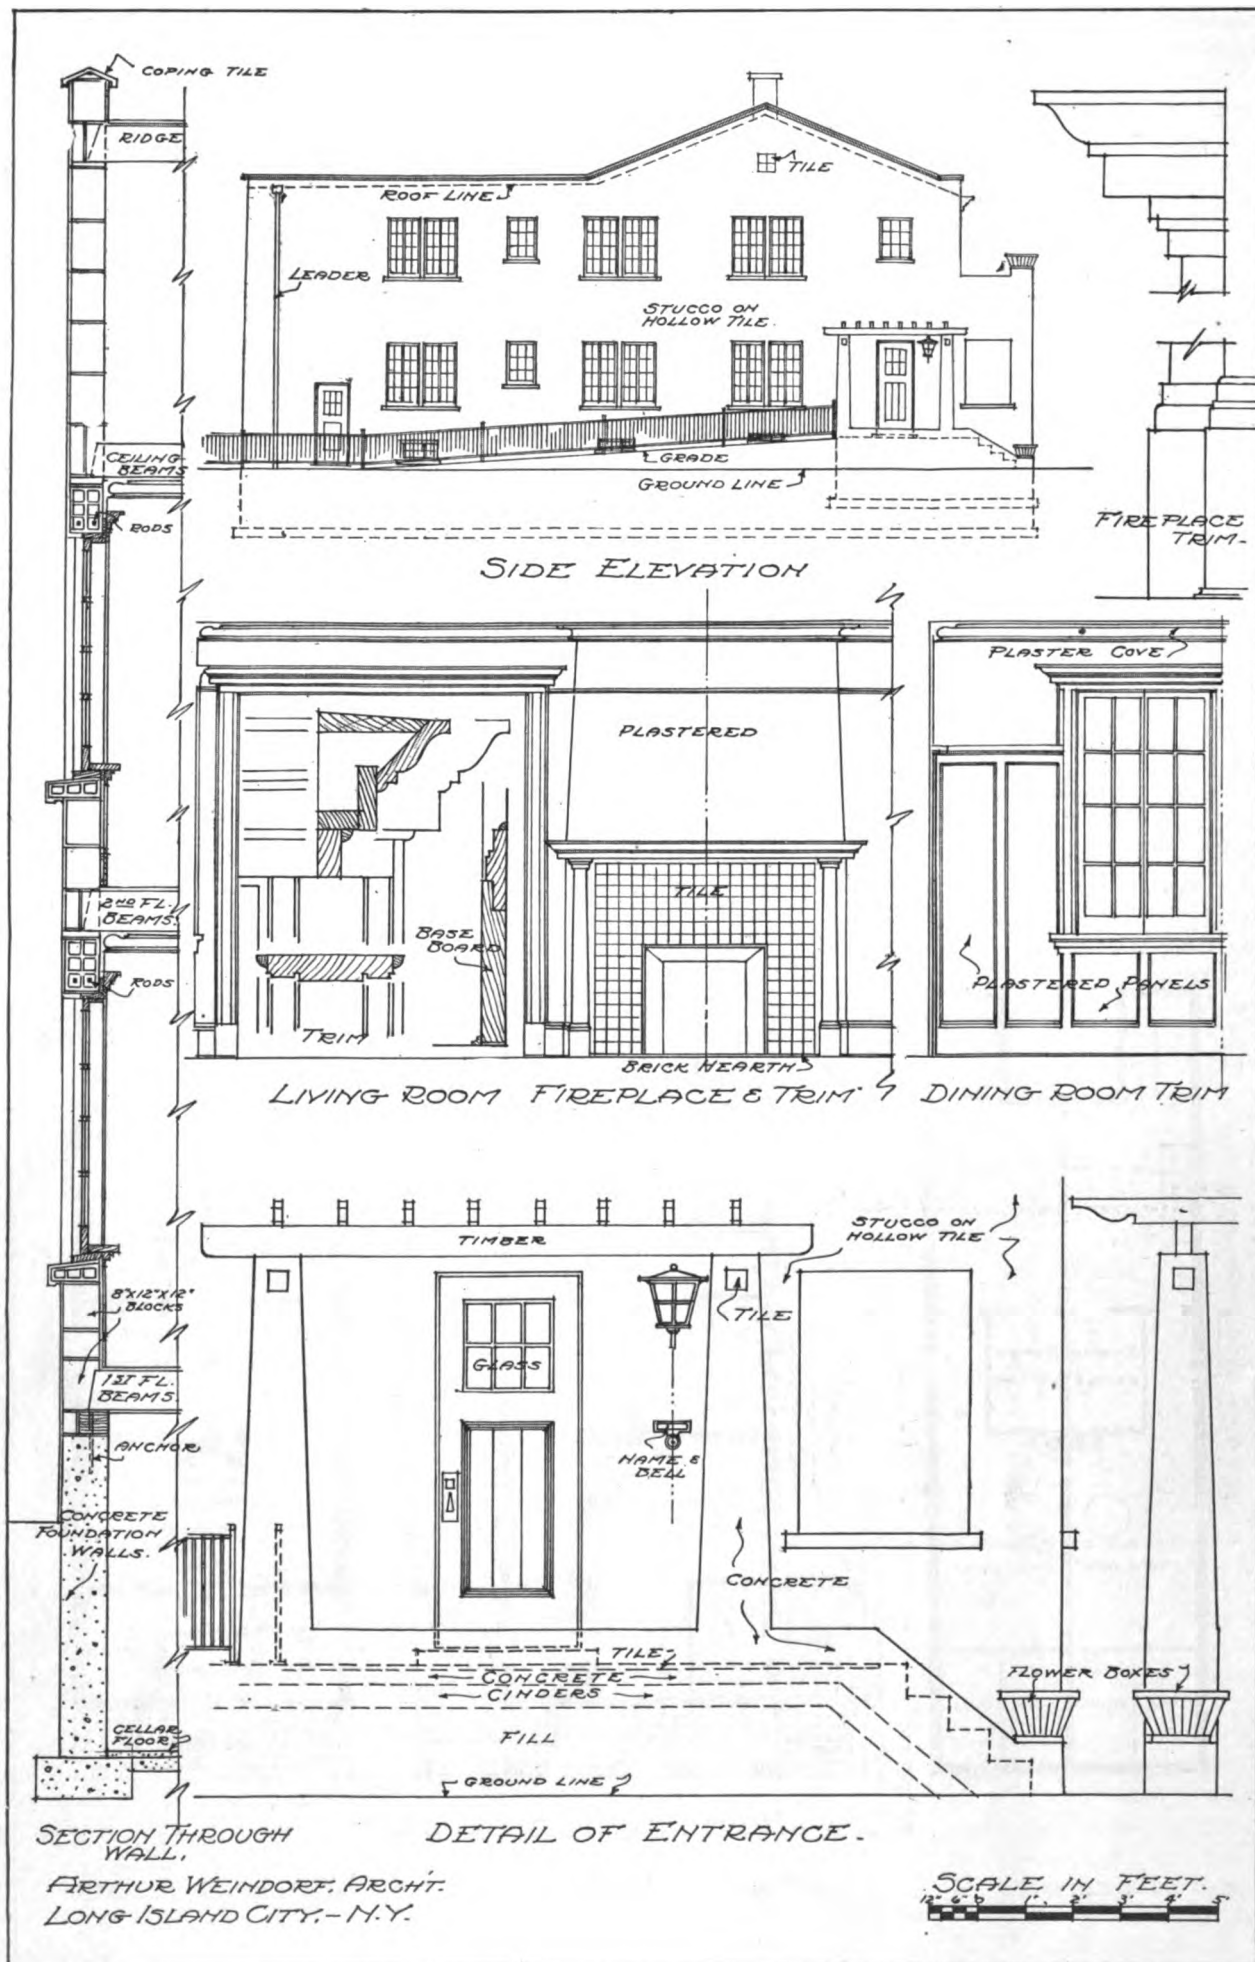

CELLAR

FIRST FLOOR

SECOND FLOOR.

Plans and Elevations of Two-Family House Shown on Colored Supplemental Plate This Month

Miscellaneous Constructive Details of Two-Family House Forming Basis of Supplemental Plate

supplied with hot and cold water, the former being supplied by means of a gas water heater.

The hardware is to be of a neat, plain bronze finish.

The lighting is to be by means of electricity or gas. The living room is to contain two drop pendants, the dining room to have one ceiling light and one side wall light. All other rooms are to have one light each.

Each apartment is to be heated by a steam heating system with radiators located in all rooms excepting the kitchen and it shall be of sufficient size

to properly heat the rooms in zero weather. Cooking will be by gas or electricity.

The architect computes the cubical content of the house as 39,777 cu. ft. and places the unit cost at 20c. per cubic foot.

The total figures of cost include a contractor's profit of 10 per cent, but do not include the cost of lighting fixtures, gas range or gas water heater.

The two-family house here shown was designed by Arthur Weindorf, Long Island City, N. Y., or care of THE BUILDING AGE, 239 West Thirty-ninth Street, New York City.

Arrangement of Sliding Partitions

The Flush Door Partition, Which Is One of the Three Principal Types—Various Details

BY E. J. G. PHILLIPS*

THE best and most substantial method of closing large openings in the flush door partition.

Fig. 20 represents an interior view of one of the new Philadelphia schools in which twenty-four of these partitions are used. The partitions can be arranged so that when opened, the doors are moved back into pockets and completely concealed or the partition may be composed of one stationary door and a number of sliding doors, all when opened occupying a position alongside the stationary door.

In Figs. 21 to 23 are shown floor plans and elevations, the first of which shows a partition in which

tracks for all of the other doors require compound curves to bring the doors into line with the first door. The meeting stiles of smaller doors are usually tongued and grooved, but for the larger doors, metal astragals are generally used. The detail Fig. 24 shows the metal astragal applied to doors 2½ in. thick and also joint for smaller doors.

In school rooms it is common practice to build blackboard panels in the doors.

A small door hinged to the jamb at "K" is used to close the opening into the pocket when the doors

Fig. 20—Good Method of Closing Large Openings is by the Use of Flush Door Partitions as Shown

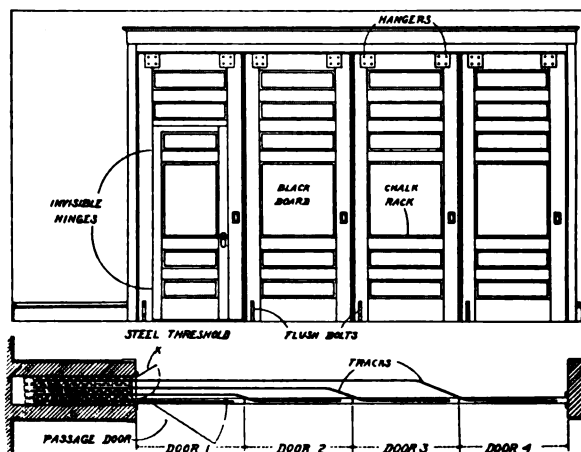

Fig. 21—Plan and Elevation of Partition in Which the Doors Slide Into a Pocket

Arrangement of Sliding Partitions—The Flush Door Type

all of the doors slide into a pocket at one side of the room. The width of the doors is not limited by the equipment, but all of the doors should be the same width except the first and last doors. The outer stiles of these doors should be made slightly wider to allow for the lap over the jamb. By using a wider stile, the appearance of the partition is improved because the exposed parts of all the stiles will be the same width. Each door has its own track, that of door No. 1 being straight, but the

have been withdrawn. It may be arranged to lock to door No. 1 and so prevent any unauthorized person from meddling with the partition. When the doors are moved back into the pocket, the front edge of door No. 1 should stop flush with the jamb, the other doors sliding back far enough to permit the small hinged door to be swung into position and locked to the front edge of the door No. 1. This locks the partition in the open position.

A flush floor bolt should be used at the bottom of each door, at the side farthest from the pocket. Each door should also be provided with a flush pull.

*Engineer Richards-Wilcox Mfg. Company.

The second plan, Fig. 22, illustrates the use of the stationary panel instead of the pocket and is of course similar in size and design to the sliding doors.

The third plan, Fig. 23, illustrates doors sliding toward both sides of the room and obviously either the pocket or the stationary panel may be used.

When it is necessary to provide a means of communication between the rooms separated by the partition, a wicket door should be built in one of the sliding doors, as shown in door 1, of Fig. 21, or preferably in the stationary panel if this is used, as in Fig. 22. A steel bar threshold as previously described, should be used. Hinges, locks and other hardware are similar to that suggested for the service doors under parallel door partitions.

Vertical cross-sections of two styles of overhead

Fig. 24—Detail of Metal Astragal

Arrangement of Sliding Partitions—The Flush Door Type

construction are given in Figs. 25 and 26. These being typical, will vary according to local conditions and they are given only as suggestions. In Fig. 25, the tracks are attached to wood headers and in Fig. 26 steel and concrete construction is shown. Two sizes of tracks are illustrated, either one of which may be used with wood or steel supporting members. The distance from top of doors to header is $5 \frac{1}{16}$ in. and 4 in. The tracks are located on 3-in. centers for any thickness of door up to $2 \frac{1}{2}$ in. For thicker doors the center distance varies an amount equal to the increase in the thickness of the doors.

The track brackets should be attached with through bolts and the header should be cased up in such a manner that access to the nuts may be had, should it be necessary to remove the track. Notice that this is provided for in both cross-

sections shown. The track brackets are generally spaced not to exceed 24-in. centers except for very light doors.

When erecting the track and brackets, care should be used to follow the plans furnished by the manufacturer, showing proper spacing and location of tracks and brackets. Strike a chalk line over the center line of each track and bore the bolt holes on this line through the header. The end brackets are provided with bumper lugs which engage corresponding lugs on the hanger apron or a stop attached to the door. These limit the movement of the doors and stop them in the correct location.

The tracks, as will be noted, are entirely enclosed with steel casings and soffits, excepting narrow slots or openings in the soffits for the pendant bolts of the hangers to travel in. The casings and soffits are attached to the brackets with

Fig. 25—Cross Section Showing the Tracks Attached to Wooden Headers

small machine screws, tapped holes having been provided in the brackets for this purpose and may be finished to match the doors and trim.

Four-wheel hangers for the larger size track or eight-wheel hangers for the smaller size track are suitable for doors weighing up to 600 lbs., but for heavier doors, eight-wheel hangers for the larger size track should be used. These hangers are constructed with knuckle jointed frames in order to take the truck curves easily. The side plates which are attached to the door are designed to reinforce and tie the top rail and stiles of the door together. To get the full advantage of this feature, the stiles should be 7 in. wide. The hangers must be located properly on the door, the distance from the edge of the door to the center of the hanger varying from $8 \frac{1}{2}$ in. to $12 \frac{1}{2}$ in. according to the style hanger used.

These partitions are used as high as 16 or 18 ft., but considering the fact that in moving high doors, the force is applied a considerable distance below the center of the door it is wise to make high doors reasonably wide to overcome any tendency to kick up and bind when moving into position.

If desired the floor guides shown in Fig. 27 may be used. Two rollers are set into the bottom of each door, one directly under the pendant of the door hangers. The guide track is formed of steel wearing strips filled in with $\frac{3}{8}$ -in. hardware flooring between. This may be built in to form a raised threshold or it may be finished flush with the main floor, according to structural conditions. It is essential to locate the curves exactly beneath the curved track above.

The flush door partition, though perfectly

Fig. 26—Detail Showing the Concrete Construction

Fig. 27—Showing Use of Floor Guides

used strictly pure lead, colors and oil. The cause for blistering has been attributed by many painters and laymen alike to early painting in seasons, painting during the hot months of July and August, others to autumn painting, and some to the damp weather and at times to the fog. It is a mistaken idea: all blistering is caused from fat or old paint, foreign to pure or fresh paint.

There are blisters caused by inner dampness from within, priming while building is under construction, wood not thoroughly dry, or wet plaster on the inside, leaks from gutters, and in some cases from pitch and sap, but these are not the most prevalent. If the under coats are not dried, but sticky, or if the work has been painted with a paint that was fat, old oil, mineral oil, fish oil, too much yellow ochre, or any material foreign to linseed oil and lead, the work will blister, notwithstanding the fact that it was done according to

Fig. 28—Plan of Large School, Showing Four Classrooms and Corridor Converted into an Assembly Hall

Arrangement of Sliding Partitions—The Flush Door Type

adapted for the smaller opening, is especially useful for large openings such as occur between two main rooms in public schools or churches. This is well illustrated in Fig. 28 which is a plan of part of a large Connecticut school. Four classrooms and corridor are converted into a large assembly hall by moving six flush door partitions. This is a good example of the efficient use of floor space.

Blistering and Cracking of Paint

There is no class of work that is so annoying and damaging to the painter's reputation, says John W. Luthe, in a paper read before the Master House Painters' and Decorators' International Association of the United States and Canada, as the blistering and cracking of paint on outside work.

Blistering is more prevalent than scaling and cracking, and the cause is not generally understood by customers and painters, many painters assuming responsibility for the blistering, although having

the best paint catechism, pure materials, July, August, or any other month included.

A priming, second or third coat of paint, composed of fresh white-lead and turpentine and oil, applied in just ordinary weather, will not and can not blister, but any old left-over paint, fish oil or petroleum oil, fatty turpentine, or too much yellow ochre, especially the cheap grade, ground in some non-drying oil, will blister after becoming painted over, although the coating was pure white-lead and colors and oil.

Has anyone ever noticed, in opening some of the blisters, that the underneath or the coats that were separated were shiny, glossy, and that the undercoat was mostly of an ochre shade or composed of considerable ochre and black?

For many years the writer's attention has been attracted to store fronts, sash, front doors and trimmings of houses or houses painted in dark colors, especially those shades composed of ochre, black, red and green, all blistered and some parts sticky. Having come in contact with many old-time paint-

ers in years past, and become very familiar with their shop methods and materials used for priming, this same old method is still found to be in use in some of the shops which believe that the older the oil and paint the better the job will be.

Results of Ignorance in Painting

Ignorance in the painting trade has caused more damage than wilful dishonesty, also some blisters to boot. In some of these shops left-overs were put in a container, barrel or tub, a considerable amount of yellow ochre was added, and material for priming would be taken from this mixture.

Any building or parts of it primed with this fat paint or all yellow ochre or any oil foreign to linseed oil will cause the following coats to blister. It is not the priming proper, so to speak, that blisters, it is the last coats. The undercoat being fat or sticky never dries.

When the last coats of paint are dry, the oil well oxidized, and the coating becomes perfectly airtight, the sun beating on this surface heats or boils the undercoat or priming, creating gas; the last coats being air sealed will expand from this gas, separating the last coats from the undercoating, whatever they may be, causing blisters. The above does not apply to some blisters, such as gas or pitch blisters, which are unavoidable.

Cracking of paint in most cases is from an undercoating not dry, and finishing coats too thick, heavy, or too brittle, too much zinc in paints, or mixed paints of an inferior grade. White-lead oil and turpentine can not and will not crack if properly applied and given a reasonable time to dry between coats.

When Cracking of Paint Is Likely to Result

A building that is being repainted with the oil paint in fair condition, and the first coat being applied too heavy or with a shortage of turpentine, and coated with a second coat before the first coat has digested or hardened, cracking will follow on certain parts of the building. Whatever applies to inside work applies to outside, whether paint, enamel or varnish.

Scaling of paint is due to several causes. Priming when the surface is damp or wet, priming materials too flat, cheap mixed paints, dampness from weather, or leaking gutters where water runs down on the inside of siding, such dampness will throw paint off no matter how, when, or what the paint consists of.

On many old houses it has been found that on the first clapboard from the water table or belt, paint is loose or scaling on the lower half or siding; also on lower parts of columns and spindles of porches, the paint was being thrown off, caused from the dampness, the lower edge of the siding being unpainted and water lodging on the water table, giving the unpainted surface a chance to absorb the moisture, causing scaling.

One other annoying part with outside work is that of alligating, which is not cracking. Cracking is where the paint cracks at right angles to the grain of wood. Alligating is when the last coats of paint have shrunk so as to leave the surface to look something like a map in miniature—like a county or township map.

Cracking only to the hard undercoating or good priming, whatever coat or coats there may be, this alligating will take place if at any time a building or surface is repainted and the first coat of paint is too heavily applied or too short in turpentine or old fat color, or too much yellow ochre and followed with strictly pure lead in oil, alligating will take place. The last coat of paint drying from the surface will naturally help to dry the first coat; when the undercoat dries, the upper gives way, and alligating takes place.

Chattanooga's Largest Office Building

What is said to be Chattanooga's largest office building is the twelve-story and basement structure now in course of erection for the Volunteer State Life Insurance Company, the location being in the geographical center of the city and on one of the highest parts of the business section. It is so situated as to have a frontage on three streets.

The foundation is built upon bed rock and has reinforced concrete caissons. The building is of skeleton steel frame construction with curtain walls of brick and tile. All floors are of concrete and tile. The architecture is Italian Renaissance, with the lower three stories of terra cotta and Tennessee marble. The main entrance will have walls and elevator fronts of white marble and floors of light gray Tennessee marble with a border and base of green Georgia marble. The doors in the main lobby will be mahogany. All inner offices will face on a court 50 ft. wide, faced with white vitreous brick. The steel work was erected by the Atlanta Ferro Concrete Company.

Use of Hollow Tile in Oakland Buildings

The City Council of Oakland, Cal., recently passed an ordinance regulating the use of interlocking tile in buildings. This includes interlocking hollow tile under the term, "masonry," and provides for a certain density of material, an ultimate crushing strength of 1500 lb. per square inch, with allowable stress on bearing members of the tile limited to 150 lb. per square inch of net area. It admits tile buildings with incombustible roof covering in Class C, and permits such tile to be used for the construction of exterior and bearing walls in Class C buildings not over three stories high, the walls to be of same thickness as brick walls. Various other provisions are also included, governing usage of hollow tile supporting floors, etc.

According to the report of the Bureau of Statistics and Information of the New York State Department of Labor the percentage of idleness April 15 was 27½ as compared with similar figures for 1915 of 41.2 per cent, for 1914 of 40.2 per cent and for 1913 of 19.6 per cent; the figures covering fifty-nine unions with about 32,000 members.

Built in five months, burned in five hours, and rebuilt in five weeks, is said to be the record of Hopewell, Va.

Design of Beams, Girders and Trusses*

A Series of Articles on the Above Subjects in
Which Only Arithmetic Is Used for the Calculations

BY ERNEST MCCULLOUGH, C.E.

THE stresses in the top and bottom chord of a bowstring truss are found with sufficient accuracy by assuming the truss to be uniformly loaded. The moment divided by the depth gives the maximum stress at the center of the top chord and throughout the lower chord, the formula being

$$T = C = \frac{wl^2}{8d}$$

in which T = total tension,

C = total compression,

l = length in feet,

w = uniform load per lineal foot,

d = depth in feet at center of span.

The chord assumes some of the functions of braces as the ends are approached where the inclination of the chord increases, and the compression is nearly

is a tie it is King Rod truss. At (b) and (c) are shown Queen trusses, these being known by the number of panels into which they are divided, and, like the King truss, being Queen Post or Queen Rod trusses as the verticals may be posts or rods.

In a system of roof framing all longitudinal members are called purlins, and all members extending from the eaves to the ridge are rafters. The top chord of a truss is composed of rafters. Main purlins extend from truss to truss, resting on the joints at the upper ends of verticals. Intermediate rafters rest on the main purlins when the spacing between trusses is considerable, and across the rafters sheathing is placed to carry the roof covering. By so doing all loads are concentrated at the upper ends of the verticals, so the truss rafters (upper chord) are in compression. Sometimes no inter-

Fig. 68—(a) A King Post Truss—B, C and D, Four-, Six- and Eight-Panel Queen Trusses

uniform throughout the length. The compression at any point distant y feet from the center is given by the following formula:

$$C = \sqrt{\left(\frac{wl^2}{8d}\right)^2 + (wy)^2}$$

The stress in the braces increases from the ends to the center as in the case of the Queen truss, and may be figured the same way. The vertical rods at the joints are in tension and the braces are in compression. The center panel is usually as wide as the height, which decreases the angles at which the braces are set as they approach the ends.

Steeply pitched roofs of the Howe truss type may be figured by the method of coefficients when the loads are uniform and symmetrically placed. They may be figured by the cumulative load method or by the shear method when unsymmetrically or irregularly loaded. In Fig. 68 the truss with one vertical is a King truss. When the vertical is a post it is a King Post truss, and when the vertical

mediate rafters are used, the roofing being carried by purlins resting on the joints.

To obtain proper results the sloping rafter of the truss is divided into equal spaces and verticals are dropped to the bottom chord (or tie). Braces extend from the foot of one vertical to the top of another. If, through any error or because it is considered best, intermediate purlins rest on the truss rafters, or the roof is carried directly on these rafters, it will be necessary to design them to carry the bending stress in addition to the direct compression.

In the King truss, Fig. 68 (a), the load, P , when applied at the upper vertex causes no stress in the rod BB . When applied at the lower end the stress is tension and equal to the load. The stress in AB = half the load, so the coefficient = $\frac{1}{2}$. The stress in the horizontal tie rod = half the load

$\times \frac{\text{half the span}}{\text{height}}$, that is

$$T = \frac{P}{2} \times \frac{L}{2d} = \frac{PL}{4d}$$

In the Queen truss the action resembles an arch in that the compressive and tensile stresses increase toward the supports in the rafters and tie, and the stresses in the verticals and diagonals decrease to-

Note in this series of articles no algebra is used. The rules are written in the modern way in the shape of formulas by using letters instead of writing in full words that are often employed. The words for which the letters stand are explained for every formula so that readers may in time understand how to read and comprehend formulas used by other writers. The actual computation is arithmetical and worked examples are given.—Editor.

*Continued from page 63 of the June issue.

ward the supports, for the inclined rafters carry part of the shear. Half of the load on each end panel is carried by the abutments and creates no stress in the truss.

In Fig. 68 (b) a load is assumed to be applied at the upper end of BC . If the load is at the lower end the rod BC carries this load to the rafter at the vertex of the triangle. If the load is applied directly to the rafter at the vertex there is no stress in BC . This will not again be referred to, as it applies to the rod in the end triangle in all trusses. Half the load is carried on AB and half goes down CD to the tie. The load on the top of the truss is increased by the load coming to the tie by the braces CD on both sides of the center, therefore it is $2P$, if the load on a joint is called P . The vertical rod, DD , however, carries only the load at the lower end. This load $2P$ from the top of the truss is carried half way down the truss to the joint and there it has added to it the load $P/2$ of the brace AB ,

this brace therefore carrying a load $= \frac{3P}{2}$. The

tie rod is in tension by an amount $= \frac{3P}{2}$

$\times \frac{\text{half the span}}{\text{height}}$

$$\text{or } T = \frac{3P}{2} \times \frac{L}{2d} = \frac{3PL}{4d}$$

In Fig. 68 (c) the rafter is divided into three equal parts. Each joint carries a load, P . The load on $DC = P/2$; on $DE = 3P/2$; on $EF = 5P/2$. The vertical FF carries $3P$. The rafter AF carries $3P/2$; AD carries $5P/2$; AB carries $3P$. The tie

rod carries at the end a stress $= \frac{3PL}{2d}$. The stress

in the tie rod on the section $TE = \frac{5PL}{4d}$. In actual

practice the tie rod is uniform in size throughout the span.

Tracing the Loads

With the examples given the student should have no trouble tracing the loads on the members of the truss shown at (d).

Each vertical is in tension by an amount equal to the load it carries. Each diagonal member, is in

compression by an amount $= \frac{xL}{d}$

in which x = amount of load on the member,

L = length of member,

d = the vertical height from the bottom to the top of the member, all measurements being on center lines.

The slope of the rafter is constant so the ratio is obtained once by dividing the slant length of the rafter by the height of the truss. The slopes change at each panel for the interior braces, so a ratio must be found for each separately.

Co-efficients for Fink truss, Fan trusses and Pratt trusses with inclined rafters have been cal-

culated for different degrees of slope and for varying numbers of panels, based on uniform symmetrical loads. Tables of these coefficients are given on pages 309-311 of the 1913 edition of the Carnegie Pocket Companion for trusses to be made of steel or wrought iron. Steel is commonly used except when corrosion is a grave danger, in which case wrought iron is preferred. All metal trusses are made of rolled shapes with riveted connections. The trusses illustrated may be a combination of steel rods for tension members and wood for compression members. Fink trusses are very generally used because most of the members are in tension and the struts are short. Partial loading can never cause maximum stresses in the parts of Fink trusses as they may in other forms of trusses.

Roof Loads

For information as to proper roof loads and the effect of wind the student is referred to pages 305-307, 1913 edition Carnegie Pocket Companion. This will also be dealt with in the chapter on Graphic Statics. Usually city ordinances specify that a roof shall be capable of carrying 40 lb. per sq. ft. of horizontal surface in addition to its own weight, this allowing for wind, snow, live load and roofing. Some cities require only 25 lb. and others 30 lb. For a steeply pitched roof 25 lb. is proper, but for a very flat roof the designing load should not be less than 50 lb. per sq. ft. Each joint in a frame carries a load equal to the truss spacing times the panel length multiplied by the load per square foot.

The Signs Used for Stresses

The author mentioned that the positive (+) sign indicates compression and the negative (—) sign indicates tension. This is the way he was taught, and thirty years ago this use of the signs was common with American and British writers. There was a certain mnemonic aid in using the signs thus for compression thickens a body and tension makes it thinner, so the "minus sign" expressed the idea of thinness. In drawings the pieces in compression were indicated by heavy lines and the pieces in tension by light lines.

Continental European writers used the signs in a directly opposite sense for strict mathematical analysis in which careful attention must be paid to the signs of quantities resulted in bringing compression out at the end with a negative sign and tension with a positive sign. The well trained mathematician needs no aid from mnemonics. The result of late years has been to unsettle American and British authors and a reader of modern books must be careful to ascertain just how the signs are used by the author. It is to be hoped that at some not distant day all writers will agree upon a definite use of the signs, but for the purposes of the present work the author believes the mnemonic value, as given above, is too great to be neglected.

The value of the building improvements for which permits were issued in Miami, Fla., in April was over \$500,000, this sum including a ten-story hotel and an eight-story office building.

CORRESPONDENCE

A Department Where Those Interested Can Discuss
Trade Topics—Every Reader is Invited to Participate

Methods of Building Construction

From D. P. Barry, Redford, N. Y.—I did not intend to comment on G. L. McMurphy's ideas of building, but when I read the article of "J. P. W.," Lane, Kansas, I changed my notion. When it comes to Kansas I'm at home. I lived thirteen years in that land of wind and shabby buildings, but we built lots of good structures, too. We were always up-to-date in most things, but often very cheap. I worked about 200 miles west of Lane, though I helped modernize a flouring mill in Junction City and went to school in Manhattan a long time ago. So I shall have to attend to "J. W. P." first. I give in Fig. 1 sketch of the first box sill I helped to make in Kansas. For cheapness nothing can surpass it. A 2 x 4 in. was nailed on the bottom edge of a 2 x 8 in. for each side of the building and the four pieces were then nailed at the corners. The studs were halved as in Fig. 2 and

Fig. 1—A Kansas Box Sill

Fig. 3—A Good Sill, but Inexpensive

sill shown in Fig. 4. A bond piece is bedded in the wall flush with the top and inside edge of the wall; the joists rest on this as well as the tenons; the studs rest on the edge of the 4 x 8 in. For such 2 in. plank as are used in Kansas one would want a double lip nut 1 3/4 in. auger. If I were building in Kansas I should use this sort of sill and would have my dealer or would myself get 3 x 8, 4 x 8 or 10 in. stuff if I needed them. Such a job will do a man more good than 100 tongues. We did this kind of work at Saranc Lake 26 years ago. All the old style joists were framed as in Fig. 5.

I prefer studs full length and get them when I can; but Mr. McMurphy's way is all right if properly done. We do that a lot here. All through this region a standard log is 22 in. diameter at the small end and 13 ft. long. This gives all our lumber 13 ft. long, and if one wanted longer stuff he would have to take his timber to special mills to be sawed. Buildings put up a story at a time stay up here as well as the others.

I prefer sheathing outside and in; if the sheath-

Fig. 2—A Stud for Use in Connection with Fig. 1

Fig. 4—Sills for a Light Timber Frame

Methods of Building Construction—Sketches Submitted by D. P. Barry

spiked to the inside of the 2 x 8 in.; the four outside corner studs could have no spur. The joists rested on the 2 x 4 in.

When I began to build for myself I fired all this, and if I were "J. P. W." I would fire his. If I cannot get timber for sills I use the style shown in Fig. 3. I used it in Kansas. The piece that "J. P. W." nails to the ends of the joists I throw out. Let the joists run to the outside of the sill and spike them to the studs. Between the joists flush with the inside edge of the sill I cut in pieces which hold the joists true and stop rats, mice, vermin and drafts. If two lengths of joists are used I cut these over the joints. This takes joists out of wind and keeps them so.

When I can get no square timber I make the

ing is smooth there is no sense in wasting time lathing diagonal. I had a rough job of inside sheathing that I did not want to fur. I put the lath on vertical without breaking any joints. For such patent plasters as we have here Adamant, Ivory, and Pulp—the lath should be no more than 1 in. wide. If lath were planed the plaster could not be pounded off. Some years ago I was called in to cut a door through a partition in a building built 80 years ago. The partition was made of 2-in. plank set close up edge to edge; the lath were not furred; the mortar was lime. I had to use a cold chisel to dig the mortar off; hitting it with the hammer was like dynamiting ice.

In looking over Mr. McMurphy's early article I find a few things calling for comment. I want a

solid corner post, built up or otherwise. When I have headers to put in requiring special attention I mortise and tenon if of timber; and if of joists I put them in as in Fig. 4. All my steel squares are 18 x 24 in., a 16-in. tongue has no favors with me. I never stud walls or partitions solid. I lay off the sills with extreme care. All the openings are marked for double studs and the plates are laid off from the sills. The studs for corners and openings are doubled full length; the section is raised, the corners nailed, plumbed and braced; the opening studs are plumbed absolutely and nailed.

If I am putting up one story at a time I do not use the method described by Mr. McMurphy. I set the upper story studs on the lower story plate. I am sending a view, Fig. 8, of a frame as I put them up. His Figs. 1, 2 and 3 would not, I fear, find favor here.

Referring to his March article, the best dimensions for saw horses, in my opinion, are 4 x 6 in. 4 x 5 in., 3 x 6 in., 3 x 5 in. in the order named. With the larger size the legs may be of hard wood and put in with an auger. Legs for the smaller

down by pushing each clapboard under the one immediately above.

When I have work to do like his Fig. 6 I do it as in Fig. 6 of the accompanying sketches. This is quickly done and equals draw bore pinning; the joint when everything is glued stays put. In Fig. 7 I show a milled outside door sill and threshold in one piece.

Some Comments on Mortar for Brick Work

From W. H. Hefelfinger, St. Louis, Mo. — Regarding Norman B. Hough's comments on my article on "Mortar for Brick and Stone Masonry," I would say that his criticism seems to be based on my classing magnesia oxide in lime as an impurity, strictly speaking. I realize it is not and stand corrected.

What I meant by taking lime as it comes, was that lime being a product the quality of which depended upon the composition of the limestone before it is burned and the great variation in the composition throughout the country gives us a

Fig. 5—An Old Style Joist

Fig. 7—An Outside Door Sill

Fig. 6—A Mitre Joint

Fig. 8—An Example of Modern Framing

Methods of Building Construction—Sketches Submitted by D. P. Barry

size should be mortised in. One can stand on these comfortably to work. We use his Fig. 3 here but we tongue or groove the ends according as we begin in the center or outside. On floors that are not level this cannot be done and corners must be dressed off as they rise above the opposite pitch.

What he calls "machine clapboards" we call "feather edge"; 4d common nails are all right for those; finish nails pull through the clapboards in this climate. I nail at random 10 to 12 in. apart; 4d are too short for the cedar clapboards we get from the Pacific coast. I never lay clapboards without gaging every one; I use a silk line frequently across the wall. Some persons line the whole wall and begin at the top and clapboard

product of different value in different localities.

Excessive dust due to air slaking was meant in characteristics No. 2.

In the statement that poor limes should not be used in plastering, I meant those limes that are slow slaking, full of small stones and cinders or other impurities which injure the plaster.

Use of Oak Flooring in a Church

From W. L. C., Chicago, Ill.—In looking over the May issue of THE BUILDING AGE I note on page 57 some comments from "Manufacturer," Rochester, N. Y., in regard to the relative merits of $\frac{3}{8}$ in. oak flooring as compared with $\frac{5}{16}$ in. parquetry strip which has no tongue and groove. I cannot

say that I agree with "Manufacturer" in regard to what he says about $\frac{3}{8}$ in. oak flooring. The increased demand for flooring of this nature speaks well for it, but a professional floorlayer may prefer to lay parquetry strips for he has a chance to do it with less cost to himself, and several strips can be laid at a time. The $\frac{3}{8}$ in. oak flooring is nailed through the tongue or blind-nailed and all stock is hand-matched in like manner. When it is laid it has the appearance of heavier stock and makes a satisfactory and economical floor. There are a number of churches in the city of Detroit using $\frac{3}{8}$ in. oak flooring which is giving the best of service.

Elevations Wanted for Floor Plan

From T. T. Carter, Bluefield, W. Va.—I am sending some sketches which may be of interest to "Sawdust," Pasadena, Cal., who asked in the May

Rush Time in the Planing Mill

From John Wavrek, Jr., Pa.—Acting upon the generally accepted hypothesis that it is good policy to prepare for conflict in times of tranquillity, I wish to present a few things for the consideration of co-workers in the planing mill. It is well known to most of us that at certain seasons of the planing mill activities there arises a condition which looms up before the management like some horrid nightmare. I am sure the manager would at that particular period just as soon be with the Allied Armies in the trenches as to stand up before the attack of the various irate contractors clamoring for their inside finish.

The particular period which I have in mind is that which develops with tantalizing certainty each year of the building season when most of the outside work at the different jobs is finished and the contractors are ready for inside work. It is customary for the contractors to devote their energies

Scale 1/16 In. to the Foot

Elevations for Floor Plans—Submitted by T. T. Carter, Bluefield, West Va.

issue for elevations suitable for the floor plans which he presented. I have made a few suggestions in connection with the floor plans, as will readily be seen from inspection of the drawings. The windows are so placed as to give sufficient light and ventilation on both floors and all rooms are private. The gables and cornice are broad, with brackets for supports. In this section of the country this type of residence is very popular.

to all outside work during favorable weather, getting the buildings under roof and generally preparing for that time of the year when the weather conditions are not favorable for outside operations. When that time arrives the demand is for inside work. Although the wise manager anticipates this condition, and in a great measure provides against it, yet it is not possible to foresee to what extent the

condition will develop. There are all kinds of stock goods carried on hand by the planing mills of any importance, but such goods can only be used in the ordinary run of houses and will not be tolerated by the architects in the better class of work. This latter kind can only be gotten out when the details are forwarded to the mill by the architects, and also it is invariably necessary to take measurements of this kind of work on the job after the grounds are placed in position. Some contractors, knowing that this condition of congestion in the mill will arise, endeavor to get ahead of it by ordering the planing mill management to have their men take the measurements before the building is in proper shape for them, and as a consequence mistakes are made. It is never safe to take sizes before the rough plaster coat at least is applied.

It is customary to allow $1\frac{3}{4}$ in. over the size of the stud for door jambs in the regular run of plaster, which is usually $\frac{3}{4}$ in., but it often happens that the plaster projects considerably beyond the grounds and this causes the jamb to be too narrow, or the carpenter must scrape away the surplus in order to use the stock as furnished. If the carpenters object to scraping away the plaster it is likely that the mill will be notified that the jambs were gotten out too narrow. This, to my knowledge, has happened more than a few times. Here there arises a condition which places one "between the devil and the deep sea." Obviously it is not a good plan to have mill work measured up before the job is in shape to do the work right.

The question naturally arises, how can we overcome the congested condition in which the planing mill finds itself when everyone is clamoring for inside finish? For one we might suggest that if the capacity of the mill allows, get more help. Surely this seems an easy solution of the problem but upon deeper thought it is apparent that this is more easily said than accomplished. In the first place the only men obtainable during the rush season would at best be of inferior quality, otherwise they would not be out of a job. On the other hand, it would not be good policy to entice a man from his employment by offering him better wages than he is getting with his present employer.

Another method employed by some concerns is to run their plants overtime. This is a practice which certainly does not pay, as experience has proven. It is a well-known fact that if a man is made to work long hours his efficiency is greatly decreased and unless offered extra inducements he will not consider overtime work for a minute. The conscientious manager has also the welfare of his employees at heart and does not wish to drive them beyond their normal capacity because he knows it will not pay him in the end. In case there are mill men available when the rush period has arrived, it would seem that the proper thing to do would be to give them employment, but with the understanding, of course, that they be the first ones to be laid off when conditions require it.

One of the objections that might be raised against the employment of more help when this rush time is on is that it tends to shorten the work for the regular men, therefore it is not apt to meet with their approval. However, that again depends on the judgment of the manager. If he wishes to run his

plant for profit—and he certainly does not run it for charity—it is incumbent on him to get the most work accomplished in the shortest time possible.

From what has been said it will be seen what an unenviable position the mill manager occupies at times and that his job is indeed no child's play. The various contractors should also take into consideration the fact that their particular job is not the only one on which the planing mill is engaged and they should accordingly be less insistent. It would, perhaps, be a good plan to adopt the suggestions of the men who proposed that in order to avoid rear-end collision of trains, the last car should be eliminated, or, in other words, by making each contractor's work first, there will no last.

I should like very much indeed to hear from some of the other readers of the paper on this subject, as no doubt there are some bright chaps who can study out a good solution of the problem which I have mentioned.

A Convenient Scaffold Bracket

From S. F. A., Boxford, Mass.—In recent issues of the paper there has appeared some little comment in regard to scaffold brackets for use in laying asphalt shingles on the roofs of buildings. I am sending sketches of a folding bracket which will fit any roof and is one which I have used for 8 or 9 years. I find it very satisfactory for the

A Convenient Scaffold Bracket, as Described by "S. F. A.," Boxford, Mass.

purpose and as it costs only \$5 or \$6 per dozen it saves time and labor, and is very economical in the end. The sketches show so clearly the construction of the bracket as well as its application that little description would seem to be necessary. It will, however, be seen that at the upper end of the bracket is an iron plate with three elongated slots through which nails are driven to hold it in place on the roof. At the lower end of the bracket are three pins which are intended to hold the upright supporting the piece on which the plank or platform rests, and which are intended to accommodate the bracket to the pitch of the roof upon which work is to be done. The upper part of the bracket is so made that the nails hold-

ing it in place are covered by the course of shingles directly above and in order to release the bracket it is only necessary to push up on it until the nail heads register with the enlarged portion of the slots when it may be slipped off and the nails will remain covered by the course of shingles as stated. The bracket itself is about 1¼ in. below the shingle butts which give sufficient space to push up and slip off from the nail heads.

Workbench for the Carpenter

From J. F. A., Ossining, N. Y.—I am sending sketches of a workbench which I made for home use and which may possibly be of interest to some of the readers of THE BUILDING AGE. The bench is mortised, tenoned and bolted together in such a way that it can readily be taken apart by simply

indicated in Fig. 4 of the accompanying illustrations. The bench is constructed of red birch with pine back. The ends KK are fastened with stair bolts. Referring to Fig. 2, J is an end panel 22¼ in. deep in the clear. The piece X is put on to level the back and front boards as shown.

Methods of Laying Shingles

From E. M. P., Robbinsdale, Minn.—I have noticed the article in the June issue of the paper entitled "Some Aspects of Modern Shingling," and in my opinion this is a very good contribution for the people who make shingling hatchets, but as to the method of laying shingles, it seems to me that the author has got things twisted; at least so far as I am able to discover in this section of the country. Some twenty or thirty years ago carpenters in this state used a line by which to lay shingles and also a chalk line—sometimes two

Fig. 3—Perspective of One of the Drawers for Nails, Screws, Brads, Etc.

Fig. 4—Drawer for Tools

Figs. 1 and 2—Front and End Elevations of the Carpenter's Workbench, Showing Position of Drawers, Cupboards, etc.
Workbench for the Carpenter as Contributed by "J. F. A.," of Ossining, N. Y.

removing four lag screws, L, and four bolts, I, as shown in Figs. 1 and 2, which represent front and end elevations of the bench. The cabinet is set in loose with two drawers, A and B, shown in the elevation, Fig. 1 and in perspective in Fig. 3. These are used for brads, nails and screws. The other drawers shown in the elevation can be used for tools. Cupboard G is used for set planes, and that marked H can be used for whatever best suits the owner. The drawers marked C, D, E and F are made as in-

chalk line marks—but this method has long since been discarded and the straight-edge used—not the line. Wherever a shingling job is done with a straight-edge every course of shingles is in a perfectly straight line, owing to the fact that the butt of the shingles rests on the edge of the member which is used as a straight-edge. Every course is nailed—something which is occasionally forgotten where a line is used and when two courses are laid at a time. In our experience we have always recommended the straight-edge.

Wall Board for the Summer Cottage

Features of Its Adaptability—How It Can Be Used in New as Well as Old Cottages

WHEN the mercury begins to rise high in the tube and most city folk leave the crowded city for the cooling breezes of the seaside, or for the refreshing restfulness of the mountain woods, the carpenter feels a demand for his services for the erection of summer cottages.

For the average person, the summer cottage must be inexpensive. Usually it is of different construction from the regular frame construction, being lighter in many ways. A weather-proof roof is the essential feature.

Popular Method of Construction

The most popular method of constructing a building of this type is to use cedar post piles for the foundation, hemlock studding and siding without sheathing or paper.

When wall board is not used, the interior treatment generally consists of exposed studding and joists, or, if a smooth wall is desired, shiplap or beaded ceiling is used. Lath and plaster very seldom find a place in the summer cottage because of the increased expense due to the customary out-of-the-way location of these buildings.

The wall board interior treatment is undoubtedly the most satisfactory. It permits of the enjoyment of the exposed timber effect without the disadvantages. It is vastly more attractive than the shiplap or beaded ceiling treatment, which has a very limited field for pleasing decoration. The difficulty and expense of transporting the necessary materials for a lath and plaster treatment puts them beyond popular reach. Then, there is the two to three-week delay waiting for the plaster to dry out sufficiently to make it healthful to occupy the cottage. In winter plaster rapidly deteriorates in unwarmed rooms.

But with wall board it is entirely different. Climatic changes do not noticeably affect it; in the spring it will be found in exactly the same condition as when the cottage was closed up in the fall.

Why Wall Board Is Popular for Summer Houses

What makes wall board so much in demand for summer cottages is its resistance to the passage of heat. Even in hot weather rooms finished with it are cool, which means days of more comfort and nights of restfulness. Yet during those cold spells that seem to come from nowhere in the middle of summer, wall board will keep the rooms snug and cozy, for it is also a non-conductor of cold. On this account the cottage may be occupied earlier in the spring and later in the fall.

The accompanying drawings show complete details that will enable a carpenter to readily erect a wall board finished cottage. Notice in the wall section the wall board panels are placed on the outside of the studding in the manner of sheathing

directly under the clapboards. Thereby a well-insulated wall is secured. The panels of wall board are applied to the ceiling from the top just opposite the common method. The partitions are constructed of 2 x 2 studs nailed on each side of the panels. It is of particular interest to observe the scheme of treating the corners of the wall and partition at the junction with the ceiling.

Of course, there are numbers of other ways to finish a cottage with this material, the ordinary method of nailing the panels to the studding and joists and covering the joints with decorative strips, for instance, but the method illustrated is selected for several good reasons: First, the exposed timber effect is in best keeping with summer cottage architectural style; second, ease and rapidity of application, and third, its inexpensiveness, considering that no decorative strips whatever are required, that no center nailing is necessary and that the nails on the edges need be spaced no closer than 6 in. apart. Also on all partitions one panel takes care of both sides.

Remodeling Old Cottages

If it is desired to remodel an old cottage with exposed timbers, to obtain a smooth wall, the panels of wall board can be applied directly to the studding as in ordinary frame construction. If the walls are already shiplapped it is a very easy matter to apply the board right over it. But if the cottage with the exposed timbers is to be treated so as to produce an interior similar to that explained for new work, the carpenter is referred to the details at the bottom of the illustration.

In applying the board to partitions, the molding on one side is first fastened to the stud. The board is then toe-nailed on, after which the other molding is put on. It is not absolutely necessary to use the quarter-round molding; $\frac{7}{8}$ -in. square strips could be used, with equally attractive results.

Value of a Builders' Exchange to the Building Industry

In discussing the value of a Builders' Exchange to the building industry, A. H. Shank, secretary of the Builders and Traders' Exchange of Grand Rapids, Mich., recently said among other things:

"A Builders and Traders' Exchange is in a very vital way affected by its location and environment. There can be no question that the contractors and material dealers made a wise choice when they decided to have an organization of the building industry of this community. It has meant much to the Builders and Traders' Exchange that it lives in and has done its work in a community where the spirit of organization and co-operation exists to such a large degree.

Wall Board for the Summer Cottage—Details of Construction for New Work and Remodeling

"From the very fact that our life and happiness depends upon our fellow men in like activity and that the men of this city meet it so manfully by their various organizations is an evidence of refinement and culture. On the other hand we may be permitted to say that the Builders and Traders' Exchange has contributed largely to the growth of this city. Of course it has helped in a material way, yet that has not been its chief contribution. It has played its part in the civic, social and business progress of the city. We shall cherish the hope that the future may strengthen the bond between the building public of this city and the Builders' Exchange that the men who organized and are maintaining this organization for better building and a more beautiful city will be appreciated for their contribution to our civic life. This bond is now consecrated by the memory of several years of service and sacrifice. If it is true that the entire building industry is profoundly concerned in the expanding influence of the Builders and Traders' Exchange this city must in a special sense feel an interest in its growth and prosperity.

"The past of the Builders' Exchange is secure. Its achievements are written in a large and fine way in the minds of the men who have made up the great building industry of our city and state. It has rendered a great enduring service to the building public of this city and state. This service has affected every phase of the industry from point of view of the cost of a building to that of ethical practice by those interested. The building public of Grand Rapids owes a debt of gratitude to their Builders and Traders' Exchange in view of its many achievements for better buildings and a more beautiful city. This debt they should repay not merely by expressions of pride but more especially by giving to the members of this Exchange the kind of support that its services to the city entitle it to receive. The building public should support the acknowledged head of the building industry, not as if they were dealing out charity, but as if they were increasing an investment.

"The Builders' Exchange is conscientiously meeting the demand for a higher type of building which is conceded to be the primary function of a modern city. It is not only enriching the knowledge of its membership but is studying the wiser application of that knowledge to the needs of the building public of the city. It is concerning itself with every phase of the building process and existing to serve the needs of the city. This work is going on in an atmosphere devoted to the highest ideals of moral and ethical practice.

"The Builders' Exchange does guarantee to the building public that any work intrusted to its members will be executed with honesty and integrity and urges on all men who contemplate building to insist that their material be furnished by and done by a man who has the Builders' Exchange guarantee."

A bill empowering the Board of Estimate and Apportionment to regulate the height and size of buildings in building zones in New York City has been signed by Governor Whitman. This bill makes possible the restriction of specified areas for factory purposes, etc.

Forethought in Building

It is a good plan when starting to build new premises to think of the changes which are likely to be made on the site and round about. How an owner profited by his forethought in this direction is told in the *Scientific American*. He believed that a business street running on a stiff grade would have to be lowered sooner or later, and so when he built at Los Angeles two hotels of concrete and masonry, he provided for this contingency.

The buildings were provided with ground floors that were set about 16 ft. below the level of the sidewalk. These were not mere basements, but carefully planned quarters for business purposes, and for years these quarters have been awaiting the change in grade which has just taken place.

Broadway for a block or so leading to the North Broadway tunnel was cut down from a 6 to 3 per cent grade, involving a drop of 20 ft. at the portal of the bore and a lowering of the tunnel; and before the hotels mentioned, the cut amounted to about 16 ft., the estimated distance when building was begun some years ago.

When the steam shovel began operations it would have been necessary to make extensive changes in most structures: new foundations would be required, the underpinning of the walls would be needful and in general the rebuilding would be so extensive as to disarrange the business of the hotels and drive out the guests.

In this case, however, the work had been done in advance so skilfully that little alteration was required. When excavating began on the street, a trench before one of the hotels had been already dug and workmen were engaged in surfacing the concrete walls which had been left rough, while they were below the surface. Then when the street and sidewalk were dug away by the steam shovel, the building was disclosed with a main floor added, and it was all ready for occupancy.

The Cement Industry in 1915

The shipments of natural cement in 1915 were, according to statistics compiled by Ernest F. Burchard of the United States Geological Survey, 750,863 barrels, valued at \$358,627, being a decrease in quantity, as compared with 1914, of 422 barrels and an increase in value of \$7,257. Shipments of puzzolan cement in 1915 were 42,678 barrels, valued at \$39,801, a decrease in quantity of 25,633 barrels and in value of \$23,557 compared with 1914.

Tests of Reinforced Concrete Flat Slab Structure

There has just been issued from the press by the Engineering Experiment Station of the University of Illinois what is known as "Bulletin No. 84" and relating to the tests which have been made by it to determine the action on concrete and reinforcing steel in floor slabs of the flat slab type of building construction. The data obtained have been analyzed, with the result that many new facts of interest and importance to designers and builders of concrete flat slab structure have been developed. The matter has been compiled by Prof. A. N. Talbot and W. A. Slater.

The Garage for the Private Car

A Well Designed Example with Some Unusual Features of Convenience—Details of Construction

THE phenomenal development of the automobile business which the country is witnessing is reflected in a measure in the impetus which has been given to garage construction, more especially perhaps that for the private cars of the suburbanite and the dweller in the rural districts. At the present day the car of whatever size serves for the purpose of transit for the business man, whether it be to and from commuting stations in the country, or to and from the city itself. It is at the same time a family utility which is more and more being appreciated, and a garage for its proper housing becomes at once a necessity on the part of the owner. That they are of varied design and construction goes without saying, for these features

grade with red Pennsylvania pressed brick above. The sill is anchored to the foundation walls with angle irons.

The exterior frame is covered with 10-in. cypress clapboards stained a silver gray. The trim is white pine painted white.

The roof is of shingles stained green, with hanging gutters carried to the drain. It will be seen that 3 x 8 in. beam ends are used over the main door in "pergola effect."

The main floor of the garage provides room for two cars, with workbench, lockers for robes, clothing, etc., and a tool cabinet, all as indicated on the plan and in the detail sketch. In the portion where the robes are kept three round broom handles are

Garage and Residence of Mr. H. L. Condé at Syracuse, N. Y., Both Being Designed by Him and Erected Under His Personal Supervision

depend in large measure upon the number of cars the garage is intended to contain, and whether it is purposed to embody in connection therewith living accommodations for the chauffeur.

As being of interest in this connection we present herewith a picture and floor plan of the garage referred to at the close of the leading article in the April issue of the paper, entitled "A Cleverly Planned Syracuse Dwelling." The garage is built on a side hill, which permits an entrance in front at grade, as shown in the accompanying picture, also an entrance to the cellar at grade in the rear.

The foundation walls are of cement blocks below

used for the robe racks. Doors are provided for both the tire and robe compartments.

Electric plugs are conveniently placed for attaching extension lights for repair work. There are trapdoors in the floor at points where the cars rest, so as to facilitate any repair work that may be necessary. This, of course, saves crawling under the cars when this sort of work is to be done. The floor is of cement and is pitched to the drain outlet.

The main doors are 1 $\frac{3}{4}$ in. pine and measure 7 ft. 9 in. x 8 ft. 1 in. They are provided with 18 lights, each measuring 8 x 10 in., the arrangement being as shown in the picture.

There are five windows on the main floor, thus affording ample daylight, which is a very important factor. All windows swing in, being hinged at the top. The doors slide on overhead track, Richards-Wilcox ball-bearing hangers and locks being used.

Narrow stairs are provided which lead to the cellar and also to the dove cote in the attic. A sliding door closes the stairway opening to the cellar when the stairs are not in use.

Several large windows in the rear wall of the cellar provide ample light and ventilation for the chicken room, which is equipped with nests, roosts, etc. This room also has flue connection with the chimney for using a brooder or incubator. The heater room is also in the cellar.

The attic is used for a dove cote and has a large window in the rear for ventilation and an outside in-closed shelf at the rear for confined birds. Openings in the front provide for other or "home" birds.

Front Elevation—Scale $\frac{1}{8}$ In. to the Foot

Floor Plan—Scale $\frac{1}{8}$ In. to the Foot

The Garage for the Private Car—Plan, Elevations and Detail of Lockers and Tool Cabinet

The electric lights are so arranged that they can be turned on or off from the house or garage, and there is a light provided over the doorway.

The garage is that of H. L. Condé, No. 22 The Hartson, Syracuse, N. Y., and was erected from plans prepared by him.

The town of San Fernando, Cal., has just passed a comprehensive building ordinance, prescribing fire limits, providing for inspection and permits, and setting definite standards for various classes of construction, etc.

Some Hints on Stippling

The process called stippling consists simply of pounding the wet finishing coat gently and regularly all over with what looks like a large clothes brush. The stippling brush is about 3 in. x 6 in., and has long bristles.

A new, clean duster will do for stippling also. The object in stippling is to remove all brush marks and produce a uniform surface.

When a wall is to be stippled, says *Carter Times*, mix the last coat with half boiled oil and half

Side (Left) Elevation—
Scale $\frac{1}{8}$ In. to the Foot

Elevation of Lockers and Tool Cabinet at Rear End of Garage—Scale $\frac{1}{8}$ In. to the Foot

turpentine, rather thick, and add a little japan drier. The paint sets quickly, and it is usual to work two men on a job, one to brush on the paint and one to follow closely with the stippling brush.

Use a 4-in flat brush and apply a full coat quickly, covering the surface as well as possible without any effort to avoid brush marks and lay on the paint evenly. The stippler will distribute the paint evenly and eradicate the brush marks.

Do not miss stippling any places and do not stipple the same place twice. Do not allow the edge of a stretch to set.

Construction of Old English Roofs

Conclusion of the Lecture by the British Architect, Arthur Keen, Commenced in the June Issue

OUR English carpenter was a man of remarkable initiative, and he was ever experimenting with new forms and methods. He realized early that the form of the stone arch might be adopted in woodwork, and he did adopt it freely and fearlessly, taking care to throw the ultimate thrust as low down as possible, because the walls that carried his work were high and were not strengthened much by buttresses. The arched form is not merely very pleasing in itself, but the ribs of timber, that form the arch, tie and bind into one solid construction the principal rafter, the wall pieces, and the cellar beam if there is one, near the apex of the roof, so that they are as if cut out of one piece of wood unbending and without thrust.

A modern timber roof truss depends entirely on two great factors: one, that timber cannot stretch, and the other that, used in short lengths, it cannot bend. The modern method was not used, as far as I know, in medieval England, although in France it was adopted freely in forming the roofs of the cathedrals, and the wonderful timber fleches that adorn the crossing of some of the French cathedrals and tower up 120 ft. or more clear above the roof were carried by timber trusses formed on the principle that we now employ. The fleche at Amiens covered with lead and weighing an enormous amount is fully 150 ft. high, and stands above a roof that is 160 ft. high off the floor and there it has stood for four centuries.

The Hammer-Beam Roof

One of the most skilful contrivances of the medieval carpenter was the hammer-beam roof. In the early trussed rafter roofs there was, as I have pointed out, a triangle at the foot of the rafter which resisted outward pressure or spreading of the roof. In a hammer-beam roof this triangle becomes much larger—it projects boldly out from the wall, and is upheld by a slanting prop or brace jutting out from a wall post below. The triangle thus supported becomes immovable, and the roof therefore cannot push the walls outward. This method, once established, was recognized as a triumphant success, and it was used in the most fearless manner with all kinds of developments and modifications. The splendid possibilities of decorative treatment that it offered were seen at once and full advantage was taken of them, while the possibilities of interchange and variety among the many parts that composed the truss gave the opportunity forever fresh treatment. If you go through the Norfolk churches you realize that the same carpenter must have worked in many of them and yet the roofs are never alike. In some the arched ribs go right up to the top, in others they meet under a richly ornamented collar beam; sometimes the hammer-beam is long and sometimes short. And

the carved and molded work takes endless forms—saints and kings are carved on the wall posts, angles on the ends of the beams and along the cornices. Carved crestings adorned the cross beams; bosses and battlement-carved leaves in the spandrils and splendid color decoration make these roofs a marvel and a glory.

Timber Roof of Westminster Hall

The finest construction of this class that we have, and altogether the most wonderful timber roof ever made, is the one at Westminster Hall, and a strange thing about it is that it was the first roof of its sort to be made—not merely the first with the great arched rib running up through the whole construction, but the first hammer-beam roof. The work of re-roofing Westminster Hall was begun in 1395, the materials having been got together during two years previously. An interesting commentary on the social conditions of the time is to be noted in the fact that Godmeston, the clerk of the work, was authorized to take the necessary masons, carpenters and laborers required wherever found, and to arrest and imprison those who resisted. The mason was also to “arrest” carmen, horses and carts, and ships and mariners for conveying the stone.

The same system is shown by the fabric rolls to have been in operation in the building of Westminster Abbey in Henry III's reign, and it hardly bears out the theory of enthusiastic Churchmen who believe that the great works of medieval times were built by the monk's themselves out of sheer devotion and love, and without remuneration, although they have never told us how the monks learned their craft. Westminster Hall was built in the reign of William Rufus in 1097, and the original roof was in two or more spans, probably three. The walls were raised 2 ft. in Richard II's reign in preparation for the present roof. There are contemporary documents that give particulars of the purchase and carriage of materials, and all the arrangements for executing the work. The span between the walls is 69 ft., and the principals are 20 ft. from center to center. The complexity of the construction, combined with the huge size of the oak timbers used in it, makes the roof an amazing production. For instance, the great collar beam of each truss is a huge log of oak 38 ft. long and more than 2 ft. deep, and it had to be got into position 66 ft. above the floor.

Everything else is on a similarly huge scale, and one stands astonished at the courage and resource showed by these old carpenters who could not only conceive such a thing, but who carried it out with such accuracy and precision of workmanship that they might almost have been handling the stuff on a bench in a workshop. The mere constructive and executive problem was stupendous, but these men

looked far beyond this side of their task; they were artists, and they made their work so beautiful that one does not know which to admire more, its constructional sufficiency or the beauty of its appearance.

The decorative work is of the finest kind, and the great sculptured angels bearing shields at the ends of the hammer-beams are some of the most perfect carved work in wood that I have ever seen.

Another roof that is interesting to dwellers in London is that at Eltham Palace, monumental in its size and the richness of its detail. It is not as sound in its design as the Westminster one, and it has failed a good deal. Neglect has played havoc with it, but it has now been taken in hand by the Office of Works, and will no doubt go on for many a year. The roof dates from the fifteenth century.

Cracking and Discoloration in Stucco Surfaces

The application of a sand-finish stucco that will not crack or discolor is a problem that has perplexed many a builder and the views of such an authority on the subject as William M. Kinney, engineer for the Universal Portland Cement Company, presented in a recent issue of *Concrete*, cannot fail to prove of interest to building contractors in all parts of the country.

He states that checking and cracking of a sand-finished stucco surface can be minimized by careful attention to details but discoloration is a matter which it is harder to overcome. It is a far more difficult matter to prevent discoloration on sand-finished surfaces than on surfaces which are given a rough-cast finish. The latter can be applied rapidly enough to complete the whole side of a house in a day's time and when once applied, needs no further manipulation. A sand finish, on the other hand, requires more time and smaller areas must be gone over in obtaining the proper texture, so that the chance for discoloration is greatly increased. Although much depends upon the use of a properly proportioned mixture, the result is largely a matter of manipulation. A great deal depends upon the skill and thoroughness displayed by the workmen. The manner in which the workmen trowel the surface will influence the color. Sometimes different shades may be seen similar to those noticeable on the surface of a newly completed sidewalk, half of which has been finished from one side and half from the other.

Overworking and overtroweling of a sand finish will bring too much of the fine material to the surface and, as in the case of sidewalks and floors, will cause trouble through checking and cracking. Overrichness of mixture is another cause of trouble and we believe that for a sand-finished stucco surface, the finish coat should generally be mixed in proportion of 1 sack of cement to $2\frac{1}{2}$ of fine aggregate.

One experienced plasterer has suggested that when the finish has been applied, floated and troweled, the workman go over the surface after the finish has begun to harden, using a float covered with soft carpet or felt, in order to even up the appearance of the wall both as to texture and color. In this way he believes surface checking can be overcome, and the chance of discoloration greatly lessened.

Hot sun or winds produce rapid drying of stucco

surfaces, which results in checking to a considerable extent; under such conditions the surface should be protected by hanging wet blankets in front of the wall and keeping them wet for several days, or by spraying the wall with water frequently after it has hardened sufficiently to prevent injury.

In discussing the same problem, J. M. Gibson of the Clinton Wire Cloth Company also contributes some interesting information. He says that outside stucco should never finish less than 1 in. thick. That allows $\frac{3}{8}$ in. for a scratch coat, $\frac{3}{8}$ in. for a brown coat and $\frac{1}{4}$ in. for the finish coat.

The utmost care should be exercised in selecting the sand for stucco; it must be absolutely free from loam or any organic matter. Not only will dirty sand prevent the proper curing of cement, but it will discolor the fresh coat. Sand used in stuccoing should be clean, coarse and angular, the cement of the best brands obtainable, and if lime putty is used, it should be well seasoned and not to exceed 10 per cent. The best hair binder or fiber should be used in the scratch coat, but it is not necessary in the brown coat. Before applying one coat on another the preceding coat should be scarified, scratched and thoroughly dampened so as to prevent the absorption of water from the new coating.

In applying the finish coat, to obtain what is known as a sand finish, a slight excess of sand is used in the mixture, and the plaster is not allowed to get very wet. The sand should be large-grained and coarse.

It is not well to trowel the external coat too much, as it is apt to cause the plaster to crack and scale off. All cement surfaces will ultimately develop incipient cracking or hair-cracks. In a rough-sand finish these cracks do not show except on close examination.

If the above specifications are followed, good workmanship and absolutely the best of materials are used with a special emphasis on clean, coarse sand, there should be no trouble in obtaining a stucco exterior which will become more beautiful as time goes on.

A Unique Broadway Building

When the new subways were planned in lower Broadway, New York City, it was necessary to demolish the southern half of the old historic Astor House at Broadway and Vesey Street, leaving the northern half with the main entrance intact. Now the section of the old Astor House which formed the entrance is to be utilized as the site of a one-story structure with a façade of marble and to be used as a cigar store. The plans have been prepared by architect Frederick Putnam Platt, 1123 Broadway, New York City.

Bricklayers were the highest paid men in the building industry in Michigan during 1915, according to figures just made public by Labor Commissioner James V. Cunningham.

The largest tree in the United States is said to be the "Mother of the Forest," a giant redwood in the Calaveras big tree grove in California. It is supposed to contain 140,619 board feet of lumber.

Sewage Disposal for Isolated Houses

A Concrete Plant Involving the Septic Tank— Some Details of Construction—The Sand Filter

By H. COLIN CAMPBELL

FOR a long time cesspools were considered the only solution of the sewage problem for isolated country homes and on the farm. In view of the possible contamination of streams by house wastes the practice of discharging such wastes into streams is not to be considered for a moment. A cesspool, even though tight and closed at the top, possesses many drawbacks, one of which is the disposing and handling of its contents when the cesspool must be cleaned; also, if the construction is not watertight, the liquids will seep through into surrounding soil, and may in that way contaminate well water.

Probably the most efficient and practical solution of the isolated house sewage problem is a properly constructed septic tank, such as is detailed in Figs. 1, 2 and 3. This tank is designed to operate wholly along natural lines; that is, no chemicals are used, reliance for efficiency being based upon the development and action of bacteria, which act upon the sewage in a natural way to liquefy solids and semi-solids, and to otherwise purify the effluent.

A septic tank should be located not nearer than 50 ft. to the residence (100 ft. would be better), and the pipe carrying the sewage from the house to the tank should have a fall of at least 1 to 40.

maintained at a fixed point, 6 in. below the top of the tank, the automatic outlet being at the right of this chamber and discharging over a 4-in. reinforced concrete weir wall to the sand filter in the right-hand compartment.

The accompanying design is based on the assumption that if the first or sedimentation chamber is 4 ft. long, it will take care of 50 gal. of sewage for each member of a household of six persons daily.

Fig. 1—Plan View of the Septic Tank

Fig. 2—Section on Line B-B of the Plan

Sewage Disposal for Isolated Houses

A grease trap should be installed to separate grease from the kitchen sink waste before the sewage enters the tank, so as to prevent clogging the tank with grease. Sewage enters through a 4-in. inlet shown at the upper left-hand corner, the incoming flow first being deflected by a 2-in. baffle board of reinforced concrete, and the current being further modified by three current breakers immediately below the baffle board at the intake. This method keeps the liquid in the first or sedimentation chamber as nearly motionless as possible, this being necessary to prevent disturbing the scum on the surface, which is essential to the growth and activity of the bacteria that modify the sewage in this compartment. Surface level of contents is always

If a family of eight is to be served, the length "A" should be 5 ft. It is assumed that one day will be required for liquids to pass through the sedimentation chamber under the baffle and over the weir upon the sand filter. The 1-in. x 6-in. current breakers are set in such a position that they will break up eddies and currents caused by the rush of incoming sewage. These boards are secured in position by toe-nailing at the ends to small pieces of lumber set into the walls when concrete is being placed.

The length of this tank should be increased 1 ft. for each additional person to be accommodated in the household. The method of construction is simple. If the ground is hard and firm, and the ex-

cavation made with reasonable care, no outside forms will be necessary, and concrete may be placed between the earth and inside forms, which are built box-like. After the reinforced concrete walls and partitions have been constructed, a "floor" form is then built underneath the desired level of the reinforced concrete top. This top or cover slab should be cast in separate pieces made to fit snugly when put in place, and provide for a manhole opening to allow access to each chamber. After the concrete is thoroughly hardened the manhole covers are lifted, the wood forms knocked down, and the boards removed from the manholes.

The baffle wall extends down from the cover slab a distance of about 1 ft. 6 in., and is 3 in. thick. It has a width equal to that of the inside width of the tanks (3 ft.), and is strengthened by means of $\frac{1}{4}$ -in. reinforcing rods, spaced 6 in., center to center, both vertically and horizontally.

Between the two chambers there is a weir or dividing wall 4 in. thick, extending from the floor to within 6 in. of the cover slab. This wall is provided with a lip so that the sewage cannot trickles along the wall but will pass through the sand filter. This lip is reinforced by bonding the ends of the

the ends of the slab and the side walls, as the slab is made of lesser width than the chamber to permit easy removal.

The effect of perforating this slab is to cause the filtered sewage to be sprinkled upon the gravel filter below; and, as it falls, it passes through an 18-in. air space, which is ventilated by means of air shafts at opposite sides of the structure. A difference of at least 8 ft. in height of these air shafts is advisable so as to create as much draft in the upper portion of the gravel filter chamber as possible. A ventilator placed upon the taller shaft will also assist to this end.

The gravel in the lower filter should be screened and well cleaned before placing, as it is desirable that the sewage be freely aerated as it passes downward toward the tile which drains the plant. Air which enters by means of this tile also serves to supply air to the gravel bed.

A "quaky" mixture, consisting of one sack of Portland cement, $2\frac{1}{2}$ cu. ft. of clean, coarse sand (all passing a $\frac{1}{4}$ -in. sieve), and 4 cu. ft. of screened gravel or crushed stone, varying in size from $\frac{1}{4}$ in. to 1 in., should be used for all of this concrete construction. Concrete should be well spaded next to

the forms to give the concrete a smooth, dense surface. The size of reinforcing rods and their spacing and location are all shown on the design in such a manner that there need be no doubt as to these features of construction.

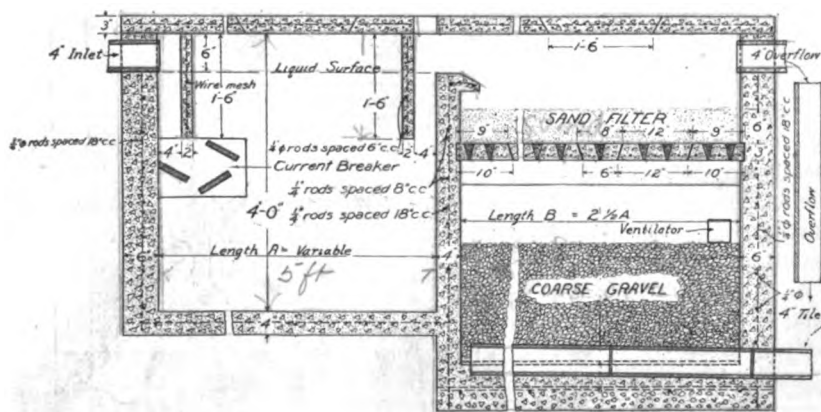

The sand filter should be cleaned out once each year, this being the only portion of the tank which requires cleaning and attention after once put in operation. Tanks of this design have been built and operated during the past three years, and prove that the theory of operation and results attained are practicable and most satisfactory.

If the natural slope of the ground permits of dropping the entire septic tank slightly below the surface,

flower beds or lawn may be made to cover site so that the ventilators will be the only portion of the construction appearing above ground.

A word of caution should be given to those persons who are inclined to accept any design as meeting septic tank requirements. Many of the designs offered are nothing but cesspools built in two compartments, in both of which the sewage remains at constant level and passes through and out of the tanks in a continuous trickling flow without having undergone the changes or modifications intended by nature to render the discharge practically harmless, as results in a well designed septic tank. Of course, the effluent must be distributed by means of tile sub-irrigation laterals that will allow nitrification of the discharge when scattered through a considerable area of soil.

One of the ways in which wood flour is utilized is in making composition flooring. The species of wood most used for making the floor are spruce, white pine and poplar.

Sewage Disposal for Isolated Houses. Fig. 3—Vertical Longitudinal Section on Line AA of the Plan

vertical rods in the weir wall at right angles to it and by one horizontal rod near the edge of the lip.

As will be seen by an examination of Fig. 2, the sand filter is 6 in. deep and two and one-half times the length of the sedimentation chamber. It is supported by a 3-in. concrete slab, 35 in. wide, divided into three sections reinforced with $\frac{1}{4}$ -in. round steel rods, and contains a large number of conical perforations. These are made in the slab by setting conical pieces of wood into the concrete before it has had time to harden in the form. When the slabs are placed, these perforations are filled with small irregular-shaped pebbles to prevent the sand from passing through to the gravel filter below. A 3-in. ledge projecting from the side wall serves as a support. The three sections permit easy removal in case it is desired to secure access to the gravel filter.

To prevent liquids that are to be filtered from running along the side wall, two end pieces of the above slab are set in shallow niches, in which clay has previously been daubed to form a tight joint. Clay may also be used to fill the opening between

Current News of Builders' Exchanges

Various Matters of Special Interest to Members of Building Organizations Throughout the Country

Building Exhibit of Detroit Exchange

THE Builders' and Traders' Exchange of Detroit, Mich., formally opened to the public on June 1 its permanent building exposition on the fourth floor of the new portion of the Penobscot Building. More than 5000 special invitations were issued, including those to members of the Board of Commerce, Detroit Real Estate Board, Employers' Association, local architects, public officials, etc.

The color note of the interior trim and furniture was mahogany, each of the sixty displays having a gold lettered mahogany sign over it, giving the name of the exhibitor and the product manufactured.

Some of the exhibits were decidedly clever. The Lumbermen's Association had two miniature houses, complete in exterior detail with glass windows, trees and lawns made of real moss, etc. The Brick Manufacturers' Association showed a small house built of brick and tile, with wood trim. There was also on display a large number of stoves, ranges, furnaces, fireless cookers, built-in cabinets, refrigerators, incinerators, panelled doors and also marble, mosaic and artificial marble exhibits, etc.

On the opening day a public reception was held from 11 a. m. to 10 p. m., during which light refreshments were served. Music was furnished throughout the afternoon by a good orchestra.

The Exchange quarters were decorated with palms and cut flowers were given as souvenirs to the ladies.

The members will hold their annual outing this year at Put-in-Bay on Wednesday, June 28.

Outing of Flint Exchange

The Builders' and Traders' Exchange of Flint, Mich., enjoyed their first annual outing as an organization on June 1, when they went to Detroit to attend the formal opening of the Permanent Building Exposition of the Builders' and Traders' Exchange of that city. A special car was chartered and the arrangements were such that the enjoyment and comfort of those who participated were carefully considered. The committee having charge of the arrangements for the trip were President Smith, A. R. Dubois, James A. Gable and Harold Roe.

At the bi-monthly meetings of the Flint Exchange special topics of interest are discussed, and at one of the recent meetings an interesting talk was given along technical lines regarding paints, oils and varnishes by Harold Roe of the well-known firm of Barnea & Roe. At another meeting a talk was given by Mr. Vandenburg on "Building Materials."

New Home of Minneapolis Builders' Exchange

The members and officials of The Builders' Exchange of Minneapolis, Minn., are considering the scheme of erecting an imposing structure especially designed to meet the varied requirements of the organization. The prime movers in the enterprise are E. E. Leighton, James Ralph, James Leck and Edward Nordbloom, who constitute the committee appointed for the purpose. This committee is being substantially aided by President Walter Thorp of the Exchange and Secretary Eugene Young.

It is understood that the idea of the committee is to have one floor of the building devoted to offices of members of the Builders' Exchange, each to have direct telephone connection with the switchboard of the Exchange. It is intended to have the entire top floor

occupied by exhibits of builders' materials of all kinds, this location being selected owing to the opportunity for effective natural lighting by means of extended skylights in the roof.

Annual Election of Portland Builders' Exchange

The members of the Builders' Exchange of Portland, Ore., held their annual meeting May 3, when the following directors were chosen to serve for the ensuing year: J. S. Seed, R. A. Hume, Oscar Wayman, James Griggs, W. H. Chambers, R. F. Arndt, Frank Stebinger, E. E. Gilmer, A. J. Bingham, Thomas Muir and F. L. Le Doux.

At a meeting held the week previous reports were presented by President Seed, Manager O. G. Hughson and other offices of the Exchange. That meeting is said to have been the largest and most enthusiastic which has occurred in the history of the organization.

Lynn Master Carpenters' Association

The new quarters of the Master Carpenters' Association of Lynn, Mass., were formally opened on the evening of May 25, when it is said every master builder of the city was present. A committee was chosen to arrange for an outing for June 24, and officers for the ensuing year were elected as follows:

President.....John J. MacDonald
Vice-President.....William Timmins
Treasurer.....L. D. Litch
Financial Secretary.....Joseph G. Fadden
Recording Secretary.....George Shattuck
Reading Clerk.....George H. E. A. Davis

The meeting submitted for discussion the no-strike-no-lockout agreement between the Master Builders and organized labor, which had previously been adopted by the Carpenters' District Council and by the main body of the Building Trades Council.

New Exchange at Little Rock

The leading concerns in Little Rock, Ark., to the number of fifty-three, held a meeting at the Masonic Temple Building on the evening of May 23, when the Builders' Exchange was organized with the following officers:

President.....William Peterson
First Vice-President.....Charles Mackey
Second Vice-President.....Charles Faubel
Secretary.....H. D. Ream
Treasurer.....J. T. Hornibrook

The officers, together with representatives of all allied trades, including general contractors, carpenters, painters, plasterers, tanners, decorators, roofers, electricians, cement workers, etc., will constitute a Board of Directors to have general supervision of the affairs of the exchange.

Buffalo Exchange Gives a Unique Dinner

The members of the Builders' Association Exchange of Buffalo, N. Y., recently enjoyed a rather unique affair, which was known as a Dungeon Dinner. This did not necessarily mean that the members ate their dinner in a dungeon, but rather, that clad in chefs' white aprons and caps and seated at individual tables made of boxes covered with white cloth, they consumed large quantities of juicy beefsteak, and during the progress

of the meal were treated to a cabaret show of high quality. The committee having charge of the affair were heartily congratulated upon the success with which the program had been carried to completion, and members are looking forward to something more of the same sort in the not very distant future.

Election of Los Angeles Exchange

The Builders' Exchange of Los Angeles, Cal., held its annual election May 19, this being the first under the new plan of organization, by which members are classified according to trades. Two tickets were in the field and the election resulted as follows:

President.....J. H. Bean
First Vice-President.....M. A. Burns
Second Vice-President.....W. R. Simons
Treasurer.....John Griffin
Secretary and Manager.....Walter Risk

The vote cast was unusually large. It was also voted to empower the Board of Directors to confer honorary membership upon individuals, firms or corporations in any line of business, such membership having previously been limited to architects.

The new officers were installed at the annual banquet, held June 15, at the Hotel Stowell.

Meeting of San Francisco Exchange

The Builders' Exchange of San Francisco, Cal., had quite a spirited annual election, and while the nominations for directors included a number of new names, in whose behalf some campaigning had been done, most of the old guard were re-elected. Those chosen were: H. Maundrell, J. D. McGilvray, Jr., E. J. Brandon, C. W. Withington, Alex. Mennie, R. J. H. Forbes, William Hayes, F. P. Fisher, E. S. Rainey, Henry Jacks and George F. Forderer.

The Exchange lost a popular member in the recent death of John W. Miller, a prominent contractor of the city for many years. He was associated with the erection of numerous buildings, including the Merchants' Exchange, the French Hospital and the Golden Gate Park Museum.

Election of Saskatoon Builders' Exchange

At the recent annual meeting of the Saskatoon Builders' Exchange, District of Saskatchewan, Canada, the following officers were elected:

President.....James Priel
First Vice-President.....A. W. Cassidy
Second Vice-President.....A. E. Richardson
Treasurer.....Andrew Rutherford
Secretary.....M. R. Pout

It is interesting to note that this is the fifth term for Mr. Priel as president. In reviewing the work for the year, Secretary M. R. Pout stated among other things that in Canada "the outlook for the present year is brighter than it has been for some time."

New Officers of Toronto Builders' Exchange

At the recent annual meeting of the Builders' Exchange of Toronto, Canada, the following officers were elected:

President.....S. R. Hughes
First Vice-President.....W. E. Dillon
Second Vice-President.....Walter Davidson
Treasurer.....John Aldridge

Arthur E. Flower, Secretary for the past three years, was tendered the hearty thanks of the retiring officers for his efficient work during 1915.

Coming Outing of Pawtucket Exchange

Arrangements are under way for the first annual outing of the Builders' and Traders' Exchange of Pawtucket, R. I., on July 19. Luncheon will be served at noon and at 4 o'clock the clambake will be opened.

The annual outing of the Master Builders' Association, which is now combined with the Exchange, has always been an event that local contractors and builders

have looked forward to with keen pleasure, for without exception a good time has been provided. So every member of the Exchange is planning to attend this season's outing.

New Publications

Modern Plumbing Illustrated. By R. M. Starbuck, 407 pages, size 7½ x 10½ inches. Fifty-eight full-page plates. Bound in cloth. Published by the Norman W. Henley Publishing Company. Price, \$4.

This is the third edition of a book which was designed to cover as far as possible the entire field of plumbing. It takes up not only plumbing as practised in towns and cities under strict plumbing regulations, but plumbing construction under conditions obtaining in country districts, where the problems which arise are often of an entirely different nature since there may be no public regulation of sanitary work.

Many readers have at different times expressed a desire to know more about the subjects which are explained in this book, and they will therefore find much valuable material to interest them. The author treats lucidly of the construction and use of cesspools, construction and action of the septic tank, automatic sewage siphons, underground disposal of partially purified sewage, pneumatic systems of water supply, hydraulic and double-acting rams, pumps, water supply by siphonage, pumping by windmill, hot water supply, protection of pipes against freezing, the softening of hard water for domestic purposes, etc.

Bungalows. By Henry H. Saylor. 209 pages; size, 7½ x 10¼ in. Illustrated by photographs and plans. Bound in cloth. Published by McBride, Nast & Co. Price, \$2.00.

The bungalow, now so popular as a summer home with those who desire to spend the warmer months of the year untrammelled by the artificialities of city life, possesses artistic possibilities worthy the trained attention of any builder or architect. Its characteristic rural air is not generally obtainable without careful study of existing types in various parts of the country. The book under review, now in its second edition, aims to provide material which will facilitate a proper planning and building of these attractive homes. Numerous photographic views depict the exteriors and interiors of many typical examples, accompanied by plans of the more characteristic.

A chapter entitled "The Fireplace" describes the construction and proper proportions of the integral parts of an open fireplace. The use and equipment for acetylene gas, electricity and gasoline vapor as individual plants in connection with the lighting problem are also briefly described. A chapter entitled "Water Supply" tells of some of the more common ways of obtaining water when there is no main to be tapped. Septic tank construction is treated of in the chapter on "Sewage Disposal," while instructive material of architectural interest is contained in the chapters on "Bungalow Types," which explain the types best suited to certain locations. Other chapters deal with "The Plan," "Foundations," "Wall Materials," "Roofing Ma-

terials," "Interior Finish," "Furnishing" and "Planting," the last named chapter describing what flowers to plant so as to secure blossoms of one kind or another from early spring to late autumn.

Practical Cost Keeping for Contractors. By Frank R. Walker, 273 pages, size 4½ x 7. Illustrated by 159 cost sheets, etc. Bound in cloth. Published by the author. Price, \$2.

It is a matter of vital necessity for any man engaged in business to keep an accurate account of expenses and especially is it so for the builder or contractor, who must verify his estimates and know the exact cost of every item if he is to make a success of his work. He will make mistakes of course, but he has no desire to take a chance on making the same mistake over and over. It has been said that a man's success is built up of mistakes, but naturally these mistakes must be known and remedied if fortune is to smile on the ambitious man.

The book under review has been written by a man who has kept time on many jobs and who has had much experience in collecting and compiling cost data on different classes of construction work. The book is therefore the result of actual practice,

not theory alone. The author considers that costs should be stated in the quantity of each class of work a man will perform per hour or per day and not in dollars and cents, for it is well known that costs in money vary considerably according to the locality in which the work may be done.

The purpose of the book is to impart to contractors, timekeepers, superintendents and foremen the essentials of accurate cost keeping and to give the methods to be employed by which the maximum results may be obtained with a minimum of labor in bookkeeping. For this reason all the forms and blanks that may be required on any job or in the contractor's office are said by the author to be illustrated and described. In each instance the origin, together with all steps necessary to gather and compute the data from checking the time, subdividing the different classes of labor and arriving at a basis for satisfactory units, are explained, tending to make the costs reliable and dependable. There are also given estimate sheets, estimate summary sheets, daily construction and material reports, labor cost records, material cost records, etc., together with the special forms required for hollow tile fireproofing, rough carpentry, masonry, electrical work, painting, as well as a large number of other subjects.

Brief Review of the Building Situation

Building Operations for May in 137 Cities Show
an Increase of 25½ per Cent Over May, 1915

THE building season is now in full swing, and activities in all parts of the country show a gratifying increase in the volume of building operations as compared with the corresponding period a year ago. The most important gains are found in the cities of the Middle and Southern States, although reports from all sections indicate that work is proceeding upon a large scale, relatively speaking. While the high prices of many of the materials entering into building construction have caused important projects to be held up, the great volume of building in the way of dwelling construction throughout the country is more than enough to offset this.

In the Eastern States, reports from fifty-two cities show an increase in the value of building operations for which permits were issued in May, as compared with the same month a year ago, of 14.42 per cent. Important in this connection is the amount of new construction work projected in Greater New York, all boroughs, excepting the Bronx, showing appreciable gains as compared with last year. In Manhattan, for example, plans for twenty-nine tenement houses were filed estimated to cost \$3,273,000, against sixteen in May last year costing \$2,106,000; three hotels costing \$11,012,000, as against none last year; five office buildings costing \$1,750,000, as against none last year, and five store and loft buildings costing \$356,000, as against three last year costing \$710,000. The total for Manhattan of all construction work for which permits were taken out in this borough was \$18,346,772, as against \$14,378,327 in May, 1915.

An examination of the accompanying table will show appreciable gains to have occurred in Philadelphia, Pittsburgh, New Bedford, New Britain, Springfield, Albany, Hartford, Holyoke, Utica and Worcester. Many of the increases are due in part to the extensions which are being made to industrial plants and also to the erection of dwellings to provide housing accommodations for the workmen and their families.

Worcester	871,102	556,860

From the middle section of the country come reports from thirty-nine cities, of which twenty-four show increases and fifteen decreases, with a resultant gain of 37.23 per cent. In the list reporting Chicago stands pre-eminent with an increase in the amount of construction projected of over 70 per cent. Reference to the figures for the month of May will be found more in detail in another column. Other cities showing important increases are Detroit, Duluth, Fort Wayne, Indianapolis, Kansas City, Minneapolis, Toledo and Youngstown. The heavy falling off in the operations in Cleveland, as compared with a year ago, is due in part to the increased cost of construction, but the difference in figures is due more particularly to the fact that in May, 1915, a permit was issued for a hotel to cost \$1,000,000, and for a large number of apartment houses involving an estimated outlay of \$2,500,000.

CITIES IN MIDDLE STATES

	May, 1916	May, 1915

In the extreme Western section of the country, embracing the territory west of Denver, reports from seventeen cities show a gain of practically 22 per cent. There are only three of the seventeen cities reporting which show decreases, these being Berkeley, San José and Stockton. The others indicate gratifying increases as compared with last year at this season.

Hydrated Lime for Stucco and Plaster Work

Hydrated lime is often added to the mortar for stucco and plaster work. In using hydrated lime for stucco work the Portland Cement Association suggests the following rules:

1. Mix with 10 parts of Portland cement, 1 part hydrated lime, dry-measured by volume.
2. Add dry, clean sand in proportions 1 part of cement lime mixture to 2 parts sand.
3. Turn until mixture is of uniform color.
4. Add necessary water to make stiff plaster.
5. For first coat on wire or lath add 1 lb. of good cow hair for each bag of Portland cement.

Hydrated lime in stucco and plaster makes cement mortar work more easily.

Obituaries

W. B. Bennett, a prominent building contractor of Pittsburgh, Pa., died at his home in that city on June 11 at the age of 61. He was born in West Fairfield, Pa., going to Pittsburgh in 1884. Many handsome residences and several public buildings in that locality stand to his credit. He was a member of the Master Builders' Association of Pittsburgh.

Charles H. Beckwith, one of the better-known contractors of western Massachusetts, died June 6 at his home in Pittsfield, Mass., at the age of 56. About twenty years ago he went from Chicopee to Pittsfield and was foreman for some years with Dodge & Devanney, at that time the largest contracting firm in the city. When it dissolved partnership, Mr. Beckwith engaged in business with D. H. Pike under the firm name of Beckwith & Pike, executing many large contracts and building some of the finer residences and public buildings in that part of the State.

Mr. Beckwith was a member of the Master Builders' Association, being instrumental in its organization at the time of the building troubles in Pittsfield several years ago.

Bennett H. Hibbard, the largest building contractor of New Britain, Conn., died at his home in that city on June 6. He was born in Torrington, Conn., in 1854, but passed most of his life in New Britain. As head of the B. H. Hibbard Company he was engaged in the mason business, and erected some of the principal buildings in that city. He was interested in the trap rock quarry business and until lately was also engaged in brick manufacturing.

MEDUSA WATERPROOFING

This Medusa Waterproofing Booklet Is Yours for the Asking

It's full of ideas that will help you on your next concrete job. It shows how MEDUSA WATERPROOFING has been successfully used in the construction of tunnels, reservoirs, municipal water works, United States Government structures, silos, feeding floors, basements, block houses and in many other building operations. It shows what successful contractors think of Medusa Waterproofing as a means for making concrete absolutely damp-proof—and for keeping it that way *permanently*. In addition it contains articles on waterproofing by men who know the subject thoroughly. You will find this booklet not only helpful but extremely interesting. Write for it today and profit by the experience of others.

MEDUSA IS THE *ORIGINAL* WATERPROOFING

Medusa Waterproofing is endorsed by the best contractors and engineers everywhere. It never "falls down" on the job. It is the original Waterproofing for concrete—and it gives the results that you want—the kind that help your reputation as a builder. Medusa Waterproofing comes in powder and paste form. *Samples sent on request.*

MEDUSA WATERPROOFED CEMENT is a combination of Medusa Cement and Medusa Waterproofing—mixed in the proper proportions at our own factory. It is made for the convenience of contractors who do not want to do the mixing themselves.

If you are interested in Waterproofing—or if you want to learn something about it, cut out the attached coupon *now*, and the Medusa booklet will be sent to you post haste.

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Artistic Effects in Concrete Construction

There is now rapidly approaching completion in two of the small parks under the jurisdiction of the Chicago South Park Commissioners, two groups of recreation buildings, and in connection with which more artistic effects have been attained in the molded concrete surface of the structures than has probably heretofore been accomplished in this kind of work. The unique feature of the construction is a rough surface in which fluted pilasters and a wide ornamental cornice of classic Doric design has been cast without showing the impression of the forms, thus giving the entire exterior walls a monolithic effect of remarkably pleasing and harmonious appearance. This style of construction was first introduced about ten years ago by the South Park Commissioners in conjunction with B. H. Burnham, a well-known architect of that city, since which time it has been developed by the commissioners until they have been able to produce the remarkably artistic features of the present structure.

The main group of buildings as shown in Fig. 1 is of cruciform shape, the length of which is 310 ft. and the

main floor, below which the side walls are faced with white enameled brick.

The balcony and main floors are of concrete construction with concrete base and maple floor finish in gymnasiums and double floor maple finish in the balconies.

At the end of the building opposite the women's gymnasium is that for men, the inside dimensions being 46 ft. x 83 ft. 9 in. There are small rooms for apparatus at the sides of the outer ends on both first and second floors. The general design is similar to the women's gymnasium with balcony extending around three sides. In the middle section of the group of buildings are the shower baths and lockers for the men and the women, the showers being arranged in the center of the building and separated by a central wall. Light and ventilation are provided through the medium of a very high ceiling with lantern light and passages adjacent to the showers covered with wire glass ceiling and a wire glass roof.

At the end of the main group of buildings in the rear of the men's gymnasium is a large open-air swimming

Fig. 1—General View of Group of South Park Recreation Buildings in Chicago in Connection with Which Unusually Artistic Effects in the Molded Concrete Surfaces Have Been Attained

width of the central portion 146½ ft. At the main or band plaza end of the structure is an entrance vestibule 15 x 21 ft., with men's and women's toilets and cloak rooms at the side, and stairways leading to the second floor. The vestibule leads to the women's gymnasium and assembly hall, which is 46 ft. x 79 ft. 10 in. with a stage 23 ft. by 17 ft. equipped with large dressing rooms in the rear at the end next to the center of the building. At the sides of the stage are passageways leading from the assembly hall to the men's and women's lockers located at the center of the group of buildings. On the second floor at the center of the entrance front is a large club room, and at its ends are wide stair halls connecting with the balcony extending around three sides of the assembly hall. At the ends of this balcony on both sides of the hall opposite the stage are small club rooms. The women's gymnasium is 24 ft. high at the sides and 39 ft. at the center, the roof being carried by open construction steel trusses supporting wood purlins and rafters. The entire structure is roofed with green Spanish tile. The balcony is 12 ft. above the

pool, a power house and a service yard. The pool is surrounded by an ornamental brick and concrete walk with long concrete benches, and is connected with the locker and dressing rooms in the main group of buildings by asphalt walks on both sides. The pool is 130 ft. long, 60 ft. wide and divided into two sections. The shallow end is 60 x 80 ft., and is designed for a water depth of 2 ft. at one end, tapering 4½ ft. at the other. The deep end is designed for a uniform water depth of 8 ft. The walls and entire floor of the pool are faced with white enameled tile.

The standard thickness of the walls of the buildings, not considering pilasters and cornice, is 18 in., composed of a 4-in. tile center dry mixed with 7 in. of concrete on the outside and 7 in. of wet mixed concrete on the inside. The dry mixed concrete is composed of two parts cement, three parts torpedo sand and nine parts broken stone which will pass through rings ¼ to ½ in. in diameter. The interior side of the wall is composed of regular wet mixed 1:3:6 concrete. The walls were built in 8-in. layers, the tile being placed first, then the

surface concrete and the wet mixed concrete on the inside of the wall last. In placing the surface concrete it was tamped very hard for a width of about 5 in. next to the tile and very little at the front. By using very small stone of nearly uniform size and a dry mix tamped in this manner, it was possible to crowd the concrete forward into the molded design of the forms, thus bringing out every detail of the design and presenting a uniform rough exterior finish. In mixing the concrete for the surface only about one-third the quantity of water was used as for the wet mixed interior part of the wall. It is said that the inspectors of the South Park Commissioners attribute the artistic results obtained in placing concrete in this manner to the uniform small size of the stone, great care in securing evenly mixed concrete of uniform moisture and the skill in tamping, to crowd the concrete forward into the molded designs of the forms. All concrete used in this group of buildings was mixed in a half-yard "Standard" low-charging mixer made by the Standard

of sizes calculated to meet these requirements is made by the F. C. Sheldon Slate Company, Granville, N. Y., who furnish the material in green and purple slates, some of which fade on exposure to warm brown and buffs, while others retain their original color, and unfading slates of rustic gray, light and dark green, and light and dark mottled purple in any proportions desired. The company states that it will be glad to make suggestions and to furnish blueprints, lay-outs and samples upon request. Suggestions for specifications, lay-outs on residences and public buildings, and details of Sheldon's graduation "A" for a 25-ft. rafter are also given. Names of recent examples of the application of Sheldon's slates are contained in another folder.

Unique Tests of Cabot's Quilt

Probably the most unique tests of an insulating material which have come to the notice of the trade in recent years were those to which Cabot's quilt was subjected in connection with buildings erected by explorer Donald D. McMillan at Etah, North Greenland, and those put up by Captain Scott in connection with his Antarctic expedition. In Fig. 2 is shown a house built by explorer McMillan in North Greenland, the picture clearly indicating the manner in which the quilt was applied to the walls during construction, while in Fig. 3 is presented a picture of the completed house nearly buried in the snow. The house was 34 ft. square, contained eight rooms on the ground floor, and was fitted with ten windows. Cabot's quilt was used as a sheathing all over the outside of the building, and the explorer states, in a letter written to a friend in Boston, that he not only did not suffer from the cold but many times the house was uncomfortably warm. In the

Unique Tests of Cabot's Quilt—Fig. 2—Appearance of the Building During Construction Erected by Explorer McMillan in North Greenland

Scale & Supply Company, Chicago, the mixer being placed at the ground level about the center, close to the side of the main group of buildings and most of the concrete delivered in barrows from this position. The point is made that this mixer is particularly adapted for this class of construction, since it has a large open end, which permits the inspector to watch the concrete during the entire mixing operation and obtaining more uniform concrete with the amount of water varied as required than would otherwise be possible.

The general contract for the construction work was in the hands of The John J. Brittan Co., 1401 Fort Dearborn Bldg., Chicago, Ill., which makes a specialty of concrete work of this character. The buildings were designed and their erection supervised by the Engineering Department of the South Park Commissioners under the direction of Chief Engineer Lynn White. Assistant Engineer J. D. Barber was in immediate charge of the work on both groups of buildings.

The "Old English" Style of Slate Roofing

Attractive or novel roof effects are always of architectural interest, therefore a folder just off the press entitled "Sheldon's Old English Slate," will cause more than passing attention. The Old English style of slate roofing, as illustrated on the cover of this folder, breaks up the checkerboard effect and relieves the "slick" appearance of ordinary slate roofs. The method consists of using slates decreasing in thickness from eaves to ridge, which give textural effect and perspective; using slates decreasing in size from eaves to ridge, which relieves the monotony of equal rectangles and adds to perspective; using slates of random widths, which breaks up vertical and diagonal line effect. Slate

Fig. 3—The Building After Completion and Partially Buried in the Snow

case of the shelter huts of the Scott Antarctic expedition the sides of the building were covered with double boarding inside and outside the frames, with a layer of the quilt between each pair of boardings. The roof had a single layer of matched boarding inside, but the outside was covered with sheathing boards driven close together, then a layer of two-ply "Ruberoid," then a layer of quilted seaweed, then a second covering of matched boarding, and finally a layer of linoleum. Upon the return of the survivors of the Scott expedition a letter was received by Samuel Cabot, Boston, Mass., from Commander Edward G. R. Evans stating that the patent quilting proved highly satisfactory and was thoroughly efficient. These tests cannot fail to prove interesting to builders everywhere, demonstrating, as they do, the insulating qualities of the material in question and proving that it is equally effective in keeping out the heat as well as the cold. The maker states that roofs lined with the quilt render the rooms below more comfortable than would otherwise be the case.

Coulson Store Front Construction

A new catalog which is being sent out by J. W. Coulson & Company, 107 West Spring Street, Columbus, Ohio, illustrates and describes in detail the Coulson patent store-front construction, which is referred to as being complete in every respect and adaptable to any store front, large or small, expensive or inexpensive. The illustrations are of liberal proportions, so that the various details of construction are clearly indicated. A special feature of the construction is the ventilating system, which allows the circulation of air in the show windows, preventing sweat and frost from forming on the glass, providing the inside inclosures are properly built and allow no warm air to enter from the store room. The ventilating tubes in the sill also act as drainage outlets for any moisture on the inside surface of the glass occasioned by condensation or in washing the windows. At the top of the transom bar are drainage openings to take care of any moisture on the inside surface of the transom glass. Among the many illustrations presented are a number showing display windows constructed in accordance with the Coulson system. Accompanying the catalog is a large blueprint giving details of the Coulson store-front construction.

Stewart Simple Heating Plant

A simple heating plant of the pipeless variety and which is said to work equally well in connection with new or old buildings of every kind, is the "Stewart,"

Fig. 4—General View of the Stewart Simple Heating Plant.

made by Fuller & Warren, Troy, N. Y. The plant consists of an ordinary furnace provided with one large supply pipe in the center for hot air. The register in the floor is placed directly over the furnace and on either side is a supply or cold air duct, the arrangement being such as to maintain a circulation of air throughout the house, provided, of course, the doors in the various rooms are left open. One particular advantage of this type of furnace, the makers state, is that the cold air may be taken from an exposed place like the hall near the front door, or other equally cold location. Furthermore, if it is desired to run a special pipe to any particularly cold portion of the house, or to a room, as for example the bathroom, it can easily be done. A furnace of this kind is usually placed in the basement as near the center of the house as possible, and the statement is made that the "Stewart" is easy and economical to install. A front view is given in Fig. 4.

Kaustine Sanitary Equipment

Under the above title there has just been issued from the press by the Kaustine Company, Inc., Buffalo, N. Y., a handsome catalog, designated as "E," which illustrates and describes the sanitary equipment manufactured by the company, and which is referred to as affording "practical sewage disposal without water or sewer." Among the early pages is a bird's-eye view of the manufacturing facilities of the company, accompanied by reference to what is designated as "a notable sanitary achievement." Reference is made to a few of the larger uses to which the Kaustine system may be applied, and numerous halftone engravings relate to buildings in which the company's equipment has been installed. The functions and principles of operation of the Kaustine system are set forth in comprehensive style, and the various features are illustrated in a way to command the attention of the architect, the builder and especially the house owner. There are blueprint suggestions for toilet-room additions and various plans for installations. These blueprint pages are bound in with the others and partake of the nature of illustrations. Everything pertaining to the Kaustine system is illustrated and described in a comprehensive manner, and at the end of the catalog is a guarantee which the company furnishes in connection with its equipment.

New Sales Offices of the Kohler Company

That progressive business ability and quality in the manufacture of Enameled Plumbing Ware is a characteristic of the Kohler Company, Kohler, Wis., is indicated by the opening of three additional sales offices at 1010 Chemical Building, St. Louis, Mo., with J. W. Keicher as manager; at 892 Van Nuys Building, Los Angeles, Cal., with Garland Mitchell as manager; and at 703 Mason Building, Houston, Tex., with J. H. Inman as manager.

Protecting and Decorating Concrete, Brick and Stucco Surfaces

Some very interesting information relative to the protection and decoration of concrete, cement, brick and stucco surfaces is contained within the covers of an attractively illustrated pamphlet of twenty-four pages which is being distributed among architects, builders and others interested by Wadsworth, Howland & Co., Inc., Boston, Mass. The primary object of the little work is to present an exposition of the merits of the "Original Bay State Brick and Cement Coating" made from a special white base carried in volatile oils which evaporate upon application. The statement is made that when applied the coating incorporates itself as a part of the material, resisting dampness and thus affording protection to the surface to which it is applied, and waterproofs the walls. The Bay State Coating is made in various colors, and is said to beautify the structure without destroying the distinctive feature of the cement. There are various reasons presented why the builder should use this Bay State Brick and Cement Coating, and the numerous halftone engravings used to illustrate the publication relate to some of the many buildings in connection with which the company's product has been used. These cover a wide range of structures, running all the way from the private residence up to the factory building and grain elevator, and among buildings so treated. Those of our readers who are the concluding pages is a list of some of the many interested in the subject can obtain a copy of the pamphlet upon application to the address given above.

Beamed Ceilings of Sheet Metal

One of the attractive features of interior treatment of modern dwellings at the present day is the beamed ceiling, this being more often found perhaps in the dining room than in other parts of the house, although it is by no means confined to a single room. It is not always that the beams are of wood, because sheet metal is now well adapted to this purpose and numerous very interesting examples of its utilization for this purpose

(Continued on page 82.)

THE PERFECT BOND

effected by COMPOSITE METAL LATH is one reason why it is so widely specified and used by prominent architects, contractors and builders.

Composite Metal Lath

is a strong, closely woven, flexible webbing of wire covered with baked brick-clay. It can be used to advantage in place of wire or expanded metal lath wherever these materials are required.

Advantages

It is a well-known fact that plaster or stucco makes a perfect bond with brick. By using **COMPOSITE METAL LATH** this clinch with the plaster or stucco is secured.

Failure due to rust is avoided because the "bricklets" and the plaster form a composite slab. This is firmly fixed to the studs, beams or supports by stapling the "bricklets," which form part of the indestructible slab itself, and are not dependent upon the wire for permanence. The uniform expansion and contraction of such a slab is insured—hence cracks are avoided. By using this material expensive form work is entirely eliminated.

COMPOSITE METAL LATH is economical—there is practically no waste of material as the plaster will not "push through." It requires less plaster and a 3 to 1 mixture can be used to better advantage than 2 to 1.

Free Samples and data covering any special use for which this lath may be desired by you, will be gladly sent upon application

THE COMPOSITE METAL LATH COMPANY

New York City

Fiberlic for Walls and Ceilings

THE principle of wall board construction is right. The question for YOU to determine is, what are the NECESSARY ELEMENTS to produce the best results.

It is not only the fibres, but the way the fibres are prepared that YOU must consider.

The fibres of the ROOT of the tree or plant are the strongest fibres. This is universal knowledge—a scientific fact.

The fibres of ROOT with the starchy and other vegetable matters taken out by a chemical cleaning process are the strongest and purest fibres—another scientific fact.

FIBERLIC WALL BOARD made from a ROOT reduced to pure fibre by a chemical cleaning process constitutes the NECESSARY ELEMENTS.

FIBERLIC averages from 25% to 100% stronger than wall boards made from mechanically prepared fibres that still contain their original vegetable matter.

Write for Fiberlic Wall Board samples and compare them with wall board made from the mechanically prepared fibres and prove for yourself the above facts.

THE FIBERLIC COMPANY
CAMDEN, NEW JERSEY

NEW and distinctive markings have been adopted for the sides of all packages of Dutch Boy white lead. Instant identification of this reliable paint material is now easy.

Each black steel keg has the familiar figure of the Dutch Boy Painter and our guaranty on the side in brilliant orange. In addition, the words DUTCH BOY WHITE LEAD, in large legible type, appear between two bright orange stripes as shown in the illustration.

NATIONAL LEAD COMPANY

Pittsburgh (National Lead & Oil Co.)

might be cited, one being presented in Fig. 5 of the illustrations, which shows the appearance of such a beamed ceiling in the living room of a residence in New Brunswick, N. J. The house was built about six years ago, the plaster had broken down and it

Fig. 5—Showing Beam Ceiling of Sheet Metal in Living Room of a Residence

was decided to put in a metal ceiling as shown. This was found so satisfactory that the owner decided to install metal ceilings in the entrance hall and in the parlor. In constructing a sheet metal ceiling of this

nature the side and end edges are hidden in grooves of the adjoining pieces so that few joints or nails are visible, the nailing being in the covered flanges. The beamed ceiling here shown was installed by Northrop, Coburn & Dodge, 43 Cherry Street, New York City, and the finish is such as to give a wood effect. We understand this ceiling is made only to order and that it can be put up directly to wood or flat tile arches or to old plaster ceilings. Furring strips may be used if desired, but they are absolutely necessary only around the wall line. The steel ceiling is in itself fire-retarding and if an asbestos lining is used above it, protection is afforded to any wood construction that is above.

Yaeger Concrete Mixers

Within the covers of an attractively printed catalog of thirty-six pages, profusely illustrated with well-executed half-tone engravings, are set forth the merits of the leading lines of concrete mixers made by the Yaeger Machine Company, 216 West Rich Street, Columbus, Ohio. The company states that a close study of the field of demand showed that what the trade really wanted was a dependable mixer that would handle an ordinary size batch and at the same time give a reasonable daily output at a saving of time and labor. The result of this investigation is the "Big-an-Little" mixer, which has proven very popular with building contractors on all kinds of work. The claim is made that it fills all the requirements of the user and is giving great satisfaction. So great was the demand for this type

(Continued on page 84.)

Forty Contractors

who have used hundreds of Hess Welded Steel furnaces all over the United States have recently written us letters telling of their experience and satisfaction with *Hess furnaces* and with our system of dealing direct from factory to contractor and consumer.

The HESS Welded Steel Pipeless Furnace. No horizontal pipes nor air ducts in cellar.

When you need another furnace, secure our estimate and free plan showing how to lay out a furnace system. Write now while you think of it; a postal card will do.

We Have Published These Letters

with several hundred more from other customers, in a small booklet. Without one word from us, this booklet will convince you that *Hess furnaces* are in a class by themselves as a heating proposition.

The contractor and the consumer are safeguarded, not only by guarantees, but by a *trial plan* which holds back the purchase price until the furnace is tested out to the customer's satisfaction. The expense is reduced and limited by the "direct from factory" purchase, which cuts out middlemen's profit and expenses.

Tim Trundle's Wheelbarrow Philosophy

"MEN who buy Barrows mostly fergit that a wheelbarrow is more than somethin' fer a man to push.

"They miss the hull point of the thing, which is that a barrow is not only a tool to work with but is the only thing there is by which the man's work is MEASURED.

"One man delivers ten barrow loads an hour and the fellow next to him only eight, from the same pile over the same wheelin' boards, to the same place. The 8-load man is worth only four-fifths as much as the 10-load man.

"And by the same token, a Sterling Barrow will make it easy for a man to do his ten-an-hour stint, while the same man, totin' the same stuff the same distance with common barrows would sweat his shirt and tire his muscles, to deliver eight barrow-loads.

"See what I mean by a barrow bein' a measure of a man's day's work, as well as a tool to work with? A certain number of tons or yards or thousands has to be carried a certain distance on every contract—the measure of all that stuff is the wheelbarrow-load.

"By bein' so much better balanced, and by runnin' so easy on its self-lubricated fiber bushings the Sterling Barrow invited every man to carry bigger loads, carry 'em faster and carry more of 'em than he'd do with ordinary barrows.

"This isn't jest theory; it's boiled-down experience from studyin' a thousand jobs.

"Isn't it good sense, then, to invest jest a little more in the cost of Barrows, if they will give you so many more ten-miles on every job?

"Why, man, the increased work done the first week will, like-as-not, pay twice the difference in cost between a Sterling and a bum barrow. And after that, the bigger workin'-ability of the Sterling is all 'velvet' on a dozen or a hundred other jobs.

"Next time you buy Barrows DON'T think of them as only two sticks, two legs, a tray and a wheel."

—Tim Trundle

that the company decided to reproduce the "Big-an-Little" in a larger size, known as the Yaeger Big Mixer. The catalog under review illustrates and describes the latest models of these mixers, and a copy of it will be sent to any interested reader of this paper who may make application for it.

The Indestructible Roof

Under the above title there has just been issued from the press a very attractive publication of 72 pages, profusely illustrated with line and halftone engravings relating to the reinforced cement tile made by the Federal Cement Tile Company, 905-907 Fort Dearborn Building, Chicago, Ill. This tile, it is pointed out, is not a novelty but the result of many years of practical experience in the field of tile manufacture, and the catalog under review is devoted to the presentation of the necessary details required to aid those interested in roof construction. The claim is made that this tile "has for its important component part the highest grade of Portland cement utilized in conjunction with other ingredients, producing through chemical reaction a material that is impervious to the severest elements." It is stated that "it is not affected by heat, cold, fire or water; that time only strengthens it, and noxious gases only tend to harden it." One of the most important improvements over the former method of manufacture is the system of reinforcement. The metal is so imbedded in the tile as to be thoroughly concealed. A tile covers an exposed surface 4 ft. long by 2 ft. wide and is $\frac{3}{8}$ in. thick. It requires $12\frac{1}{2}$ tiles to cover a square, that is 100 sq. ft., laid on a purlin spacing of 48 in. The parts interlock and are self-adjusting, thus providing in every way for expansion, contraction and vibration. The color is said to be a permanent red and no painting is required. The halftone illustrations relate to buildings in connection with which the company's product has been used.

Millers Falls Handbook for Mechanics

A handbook for mechanics, which contains a great deal of information that every mechanic needs, whether he be a carpenter, a metal worker or machinist, and which has been compiled and edited by Edward R. Markham, an instructor in machine-shop practice in the Rindge Technical School, Cambridge, Mass., has just been issued by the Millers Falls Company, 105 River Street, Millers Falls, Mass. The book is of handy size to fit the pocket, being $4\frac{1}{2}$ x 7 in., and has sixty-four pages. It contains valuable tables and is illustrated with diagrams wherever such are necessary. It treats with such subjects as "How to figure board measure, shingles, paint, stone work and brick work; the weight per foot of wood; wood-staining recipes; putty, cement and glue recipes; the number of nails to a pound; the weight of roofings; the weight and volume of fuels; information on grinding wheels; the coloring of steel and brass; the strength of chains; the weight of round and square iron and steel; the composition of alloys; the tensile strength of boilers; how to figure boiler pressure; how to figure horsepower," and more than fifty other subjects. Lengthy technical descriptions have been purposely omitted from the book, which has been written in language that can be easily understood and contains nothing but solid worth-while facts that can be used in every-day work. Because of the cost of this book, it is not offered for general distribution. A plan, however, has been worked out whereby the dealer can give his customers an opportunity to secure a copy of it. A quantity of folders is provided to the dealer to which is attached a postcard that can be torn off and mailed to the Millers Falls Company, which will forward the "Millers Falls Handbook for Mechanics" with the dealer's name and address printed on the front cover.

The Carter Paint Calculator

Under the above title there has just been issued from the press the fourth edition of a little work of interest to painters and builders. It is of a size convenient to carry in the vest pocket, and within its covers direc-

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

Full Speed Ahead On Those Construction Jobs With the FEDERAL Doing Your Hauling

Materials and tools get to the distant jobs about as easily and quickly as to those nearer headquarters—for distance makes little difference to the Federal. It will enable you to branch out and do distant jobs easily and profitably. One builder hauls an enormous quantity of material by combining quick loading with the speed of the Federal on the road. He provides his two Federals with extra bodies and can transfer a loaded body containing mill products, sash, doors, etc., onto his Federal in less than ten minutes, including the time taken to remove the empty one. He wastes no time in loading. He wastes no time on the road. He hauls big quantities and reaps big returns. And he uses the Federal to do it.

Write us for practical reports showing costs and results of Federals in the building business. Our magazine "Traffic News," illustrating some of the most interesting true stories of Haulage will be sent free upon request.

tions are given for estimating the quantity of paint required, as well as the kind of paint to use for a given purpose; how much paint for a certain building and how much lead and oil and colors are needed to make the paint. It also tells what to do when a job is going wrong, how to estimate quickly the gallon costs as well as much other information along this line. Several pages are given up to harmonious color combinations arranged for ready reference. There are also suggestions for painting cypress, pitch pine and other woods containing a considerable amount of gum or sap. The "Calculator" is published by the Carter White Lead Co., Chicago, Ill., and the price is given as 25 cents.

The "Hero" Pipeless Furnace

Many logical arguments are advanced by the Charles Smith Co., 57 West Lake Street, Chicago, Ill., on behalf of the features of the "Hero" pipeless furnace, attention being called to the fact that the equipment will supply a generous volume of fresh, warm air to the occupants of a cottage or bungalow at less cost for installation than the usual furnace outfit and at the same time will provide all the advantages enjoyed by more pretentious homes. The pipeless furnace is referred to

Fig. 6—The "Hero" Pipeless Furnace

as being superior to a stove and requires less time to set than the installation that involves a series of warm air pipes running to the various registers. The furnace is set directly under a large register face which is placed as near the center of the building as possible. This register is divided into a central heat outlet and an outer circulation return air inlet. The circulation is rapid and complete, reaching all parts of the house which communicate with the room in which the register is installed. The chill of upper quarters is taken off by means of floor register openings made through the ceilings of the heated rooms below. The "Hero" pipeless furnace is made with the fewest possible parts and joints, and the latter are made very secure so that the warm air distributed to all parts of the home may be pure and uncontaminated with gases and smoke. The equipment has a solid, one-piece base and a large ashpit that insures ample draft and perfect combustion. The firepot is deeply corrugated inside and outside alike. This greatly increases its strength and practically doubles its radiating surface, besides adding many years to its durability as compared with a smooth firepot. The firepot has deep cup joints, and the best asbestos furnace cement is used. The fire dome is corrugated in the same manner as the firepot and its surfaces radiate the

(Continued on page 88.)

Can You Stand on One Foot?

Perhaps for a few minutes, but even during this time your balance may be swinging. On two feet you are solid. So it is with "Trouble Saver" Brackets. Notice the two sturdy legs. These brace against each other at the outer end, thus preventing any side motion.

You can erect as many "Trouble Saver" Brackets in five minutes as you can wooden scaffolds in five hours. No nails, no bolts, no nuts—not a screw.

"Trouble Saver" Brackets will prove their worth. We will lend you some for a trial. Write for proposition.

The Steel Scaffolding Company

EvansvilleInd.

Perhaps some of my fellow-workers would prefer the **Oblong Carborundum Combination Bench Stone** to the round.—The difference is only in the shape.—Like every other Carborundum Stone they cut quick and clean—give your tools that keen, smooth, edge—an edge that stands up. Every Carborundum Stone is uniform throughout—it has no soft spots—won't get slick—and it *will cut*.

You'll find the combination stones mighty handy—one side is coarse grit, for bringing the tool to an edge—the other side fine and smooth—to give the tool a keen finished edge—really two good stones in one. You can always rely upon Carborundum Stones.—I know, because I use them.—I find them a tool-kit need—a work-bench necessity;

SOLID DOOR SECTION GLASS DOOR

We take pleasure in calling your attention to the construction of our "No Warp" Sanitary Doors, as illustrated above. They are made in the best manner, having cores formed of thoroughly seasoned laminated Chestnut stiles and rails, cross-framed and doweled together, and covered with 1-8 inch face veneers, and **WILL NOT WARP OR TWIST.**

We recommend them in all cases where sanitary doors are desired, and guarantee them for one year against defects due to the use of improper material or defective workmanship.

Manufactured by
HYDE-MURPHY COMPANY, Ridgway, Pa.

New York Office,
10 East 43d St. Pittsburgh Office,
Liberty Bank Bldg.

direct heat from the fire. It is made high enough to provide ample room for free combustion and still it catches the direct heat from the fire. In the radiator the products of combustion pass from the center to the lower section of the radiator at the back, then forward on both sides to the front, where they pass to the upper section and back to the smoke outlet. Thus an extremely long fire travel is assured and on account of its peculiar construction all the hot gases are utilized. The "Hero" furnace is made in all the sizes adapted to residence work. The company will be glad to co-operate with contractors and builders to the point of giving the best advice as to the size of equipment that should be used for certain houses and will recommend the best method of installation if a rough sketch of the structure is furnished. Some handsome catalogs, profusely illustrated, have been published, any or all of which may be had on application to the company at the given address.

New Catalog of Starrett Tools

We have received from the L. S. Starrett Company, Athol, Mass., a copy of an attractive publication of 336 pages, illustrating and describing leading lines of mechanics' tools turned out by the company in great profusion. The work is known as "Catalog No. 21," and in compiling it special care has been given to grouping together tools of the same classes and to presenting the facts in regard to the uses of the tools as briefly and as clearly as possible. The catalog is profusely illustrated and contains sixteen more pages than the previous edition, known as "Catalog No. 20." Several of the tools formerly illustrated have been improved in design, and on account of the advance in prices of practically everything used in the manufacture of the tools the company has been compelled to increase many of the prices in the catalog. As the quotations given in Catalog No. 20 are no longer in force, it is essential that the mechanic, in order to note the correct prices, secure a copy of Catalog No. 21. This can be done by direct application to the company at the address given, or from the local hardware dealer. Some of the new tools shown in the new catalog include quick-reading steel rules, drop-forged steel combination squares with metric and English graduations, improved bevel protractors with metric and English graduations, Yankee 1-in. micrometer calipers, hack-saw frames, cutting pliers, pin punches, metric and English folding pocket rules and vernier height gage. There are a number of valuable tables among the closing pages of the catalog and a general and numerical index, all of which will be appreciated by the mechanic into whose hands a copy of the publication may come.

Hints on Slate Roofing

Slate has been in use for a sufficient length of time to have its wearing and fireproof qualities well demonstrated by actual practice, and the familiarity of the trade with the merits of this product therefore render interesting any information in regard to the laying of slate. Material prepared along these lines is to be found in an illustrated booklet entitled "Slate Roofing," now being sent out by the Bangor Slate Mining Co., Bangor, Pa. Within its covers are to be found tables and information concerning the various sizes of slate, their exposure to the weather when laid, the number of pieces to each square, the quantity of nails required, also rules for measuring roofs of slate, either plain, or with hips, valleys, gables, etc., together with plan for laying slate, starting and finishing, the necessary strength of building for slate, pitch of roofs and other information concerning slate which is likely to prove of interest. A copy of the booklet may be obtained without charge by any reader upon request to the company named.

The "Archer Special" Concrete Mixer

The most important requirements for a concrete mixer are that it shall be able to mix a rich, uniform batch of concrete of any proportions and that it be portable and easy to load. The "Archer Special" is

(Continued on page 90.)

Stanley Rabbet Plane No. 278

The sides and bottom being square with each other, the plane will lie perfectly flat on either side.

It has an adjustable fence which slides under the bottom, regulating the width of the cut.

It is fitted with two spurs, one on each side, for working across the grain—also an adjustable depth gauge.

As both the fence and the depth gauge can be attached to either side, the plane is suitable for either right or left hand work.

The front part of the plane can be easily detached, thus providing a bull nose plane for working close up into corners or other difficult places. The cutter is one inch wide and is adjustable.

Length over all 6½ inches; weight 2 lbs.

Price Each \$1.75

If you cannot procure same from your hardware dealer, we will be pleased to forward you one, postage prepaid, upon receipt of price

PULLMAN MFG. CO.
8 Industrial St. Rochester, N. Y.

Manufacturers of
Pullman All Steel Unit Sash Balances

said to have been designed to meet these requirements and to secure portability the mixer is built with most of the weight placed over the wheels so that when the platform is raised about three feet the whole machine balances. To aid in this portability, two legs instead of another set of wheels are placed under the platform end of the machine. These legs are also claimed to help reduce vibration, since when four wheeled mixers are used it is often necessary to put wooden blocks or braces under them in order to take up such vibration. The mixing action is secured by the bucket and blade method. The discharge spout is so arranged that the drum can be quickly emptied. The mixer is loaded through a hopper so arranged as to be just the right height to catch under the front end of the wheelbarrow tray and to be as far away from the unloading crew as possible. A feature of the machine is the end discharge which enables it to discharge into the "forms." Another feature, furnished when desired, is a batch hopper and gate, which provides that while the machine is mixing it can be loaded, the gate keeping the unmixed from the mixing material. When the discharge is over, this gate is lifted and the aggregate goes into the hopper so that no time is lost. The mixer frame has all parts riveted together through heavy gusset plates. Bolts with patented absolute lock nuts are used wherever it is impossible to use rivets. The power is furnished by a 3-hp., battery ignition, hopper cooled gasoline engine with a speed of 450 revolutions per minute and running, it is said, on from 1½ to 2 gal. of gasoline a day. Hoist or steel housing are provided when desired. A booklet entitled "The Archer Special" contains interesting illustrations of these machines in use; also descriptions, partial list of users, etc. It may be obtained from Archer Iron Works, 2440 West Thirty-fourth Place, Chicago, Ill.

A Book About Slate

The slate roof of the Saxon Chapel, Bradford-on-Avon, England, is said to be 1000 years old, but the Bangor Slate Association in its comparison of the annual cost of slate with other materials conservatively estimates the life of a slate roof as being 60 years, the cost per year being 16-2/3 cents. A table showing the cost of the popular roofing materials F. O. B., total cost laid in eastern Ohio, approximate life and cost per year is contained in a little work entitled "A Book about Slate" sent out by the Bangor Slate Association and obtainable from J. Bray & Co., East Bangor, Penn. The pamphlet also contains much other interesting information regarding slate and is illustrated by line cuts.

The Bessler Movable Stairway

The Bessler Movable Stairway Company, Akron, Ohio, has just issued an interesting booklet entitled "The Modern Way Up," which tells all about the Bessler Movable Stairway, brief reference to which was made in these columns a short time ago. The stairway is intended to replace stationary stairs leading to upper rooms of a building, and when in use it presents a strong, well-built flight of stairs, but when no longer required it can be made to fold up into the ceiling with nothing visible except a neat panel, finished to match the remaining woodwork in the room. When it is desired to cause the stairway to disappear the stair-horse is rolled up on the panel and when in this position it is swung up into the ceiling by means of a powerful spring barrel concealed under the stairs and by the aid of the counter balance formed by the now projecting stair-horse. When the stairs are wanted for use the panel is pulled down from the ceiling by means of a small chain and the stair-horse rolled down the panel.

TRADE NOTES

The new concrete pier now being erected by the City of Chicago as one of the features of a great harbor plan is said to be probably the largest structure of its kind ever built into fresh water. The concrete used in the construction of the superstructure is being

Why Waste Lumber?

Use 2-E Flexible Concrete Forms

Here is a unit system of forms for hollow or solid wall concrete construction that will save its cost in the first few months you use it.

It is the simplest, least expensive and most rapid method in existence. No lumber required save one plumb or corner board at each corner with the necessary braces for same.

Made of metal; supporting frames a rigid truss. All parts interchangeable. Absolutely guaranteed.

Get details at once.

2-E Flexible Concrete Forms Eagle Wisconsin

Here's a New Vise "YANKEE" No. 1993

With Swivel Base. DETACHABLE

Quickly detached from swivel base by the turn of a set screw; and being accurately machined all over can be used in any position as a jig for special work on drill press, shaper, etc.

Holds work rigid at any angle with use of the special grooved block.

The swivel base is easily and firmly locked and released in any position by a short movement of lever at the side. Jaws 2 3/4 in. wide, 1 7/8 in. deep, opening 3 1/2 in., base 7 1/2 in.

Ask your dealer to show you.

Let us send you the "YANKEE" Book. A postal brings it.

Tells you all about the "Yankee" line

TROKAL LIQUID FLOOR FINISH

Another member of the "Nice" family. You will like the results it gives. There is nothing more sanitary, more durable or handsomer than bare floors, linoleums, etc., finished with "Trokal."

Send for catalog on Varnishes, C-M-T Coating, Paints, etc.

EUGENE E. NICE

Philadelphia, Penn.
Camden, N. J.

mixed with 7 Marsh-Capron Rail-Track Mixers built by the Marsh-Capron Mfg. Company, 1415 Lumber Exchange Building, Chicago, Ill. A four page folder containing a halftone engraving of this structure and various pictures of their mixers has just been issued by the company, with brief descriptions thereof. There are also illustrations of the mixers in use and numerous testimonials from users of them.

The L. & I. J. White Company of Buffalo, N. Y., one of the oldest edge tool and machine knife manufacturers in the United States, has very recently changed its management. Walter S. Walls, for the past ten years superintendent of the company, has been elected president and general manager; M. R. R. Thompson, who has been handling the advertising, was elected treasurer, and continues to take care of the advertising. John W. VanAllen, as vice-president, and Frank H. Hamilton, as secretary, were continued in office.

Of interest to the carpenter and the builder who has need of clamps in the making of doors, mitre joints, etc. is a booklet that is being sent out by James L. Taylor Mfg. Co., Poughkeepsie, N. Y. It is entitled "Taylor Clamps" and contains illustrations, descriptions, prices and weights of these clamps together with specifications of certain styles. A partial list of users is also contained, among which are United States Navy Yards, railroads, etc.

Many interesting illustrations of houses in which products of the Sandusky Cement Company, 624 Engineers Building, Cleveland, Ohio, have been used are contained in the May number of the *Medusa Review*. An examination of the numerous photographic views contained therein is apt to afford the ambitious builder or architect an opportunity of enlarging his ideas in relation to houses built of cement, thus enabling him to better please a client who desires that type of dwelling for occupancy.

The builder who uses an automobile in connection with his business will be interested to know that all winners of the races held recently at Sheepshead Bay, N. Y., used Dixon's Graphite Automobile Lubricant made by the Joseph Dixon Crucible Co., Jersey City, N. J. In connection with the products of this company, it is also interesting to note that Dixon's Silica-Graphite Paint was used on the steel work of the \$150,000 First National Bank Building, Gastonia, N. C. The pigment used is said to be found only in the Dixon Company's mines at Ticonderoga, being composed of graphite and silica, both of which are of flake formation and have about the same specific gravity. The vehicle used is pure, boiled linseed oil.

Smedley Roofing & Supply Company, Amherst Building, Pueblo, Colo., has just commenced business in builders' supplies in the territory named, and is desirous of receiving catalogs from manufacturers of goods in which they are likely to be interested.

John E. Widlund has just opened an office for the practice of architecture at 1 Cherry Street, Ansonia, Conn., and is desirous of securing samples and catalogs from manufacturers of all kinds of building materials.

At the annual meeting of the Cement Products Exhibition Co., held in Chicago, Ill., the latter part of May, the following officers were elected: B. F. Affleck as president, A. Y. Gowen as vice-president, Blaine S. Smith as secretary and J. U. C. McDaniel as treasurer.

George G. H. Marvin, for 35 years connected with the L. & I. J. White Company, Buffalo, N. Y., maker of edge tools and machine knives, and for 23 years president, treasurer and general manager of that concern, has resigned.

Traditions Die Hard!

—but the "good old things" must give way to the better things.

Lath and plaster must give way and is giving way, for the more durable, stronger, stiffer, more economical and altogether more satisfactory

Trade-mark Reg. No. 94745

This is no ordinary wall board—it is a wall board in a class by itself, the *only* wall board with a center core of kiln-dried wood slats, else we would not claim it to be *better* than lath and plaster. It does not have to be paneled, but can be made into walls and ceilings smoother than lath and plaster. Can be decorated by any method—even papering—which other wall boards cannot stand.

Are you going to stick to tradition or give your customers the more modern and more satisfactory wall lining in their buildings? *Talk to us* about some of the common false notions on the subject of wall boards, and let us make clear to you just what you're overlooking.

The Compo-Board Company

5778 Lyndale Ave. No., Minneapolis, Minn.

GARAGE EQUIPPED WITH SIX DOOR OUTFIT, OPENING 18 FEET WIDE
DR. J. W. DREYER, OWNER; JOHN ARMBRUSTER, CONTRACTOR

Designed to meet the demand for a fixture that will allow hinge doors to fold and swing inside of building requiring only minimum space.

This fixture is not recommended for doors over 3 feet wide.

No. 435 R-W Sliding-Folding Garage Door Outfits

Four doors hinged together in pairs are required for each opening, one pair folding to the right and the other to the left. When needed, however, five or six doors can be used, in which case the center doors swing free, making ideal entrance doors. Will stand at any angle depending, however, upon the width of the wall space adjoining the opening. Where wall space is greater than width of doors, same can be made to fold back when open, parallel with the front walls. Blue print showing erection details furnished with each order.

MORE MONEY FOR THE CARPENTER!

Don't take our word for it that these books will enormously increase your earning capacity. Get them into your home or shop—free—and determine their value for yourself. The books themselves, not what we say, must convince you that you need them, so send the coupon to-day—now—and the entire eleven volumes will come to you at once, express prepaid. If, after a full week's trial, you decide to keep them, you can buy them at half the regular price and on the easiest of easy payment plans.

New 1916 Edition Cyclopedia of Architecture, Carpentry and Building

consists of ten large volumes, handsomely bound in half morocco, gold stamped, containing 4,760 7 x 10-inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross indexed for quick, easy reference.

PARTIAL TABLE OF CONTENTS

Mechanical, Freehand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

Plan Book and Consulting Service FREE

We give free to every purchaser of our Cyclopedia of Architecture, Carpentry and Building, a copy of "Modern American Homes," a complete and up-to-date plan book. Contains plans and specifications for 168 structures, including excellent exterior and interior views, detailed estimates, etc. Designed by leading architects, it covers city, suburban, and country homes; bungalows; summer cottages; tent houses and camps; apartment houses; garages, and public buildings. 224 pages, 9 1/2 x 12 1/2 inches, and 426 illustrations. Printed on enameled paper and substantially bound. With this plan book in your shop you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect—you can offer him his choice of practically every type of home. This saving of the usual architect's fee should get you the business.

In addition we give free with each set a year's consulting membership in the American Technical Society. Through this service you have the assistance of a staff of architectural and building experts. These men are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

Send for this great combination today

We will send the complete eleven volumes to your home for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet your expectations they may be returned at our expense. If you keep them send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80—regular price \$50.00—has been paid. Remember—the consulting membership and plan book are included absolutely free. Can you afford to let \$2.00 a month—50c a week—stand between you and success? The consulting membership alone is worth many times the first cost of the books. Fill in and mail the coupon—NOW!

At Last! A Practical Home-Study Course for

CARPENTERS

FOREMEN—SUPERINTENDENTS—CONTRACTORS
and all other men in the Building Lines

Plan Reading, Estimating,
Architectural Drawing, Contracting, etc.

This is a course for practical men. We send you actual blue print plans of buildings now being built or recently completed. Practical training, not book knowledge, is what you want—it's what we give. When you think of the opportunities this training offers, you will take time—right now—to mail the coupon for full information.

To Succeed In any branch of the building business you must have a complete knowledge of plans and specifications. You must be able to estimate closely the cost of material and labor. Guessing won't do—you must know. This knowledge is what makes successful foremen, superintendents and general contractors. This knowledge means money—thousands of dollars—to any builder—to you!

Your spare time is enough. You can master these subjects in your own home by this new, easy, quick method.

This elegant set of Drawing Instruments and Complete Outfit furnished FREE to our Students.

Special Trial Offer!

For only \$2 we will send you the complete set of working blue print plans for a large residence just completed in Evanston, Ill. Also the complete specifications for this job. We will also include questions concerning the plans and a complete itemized estimate showing how to figure the cost of the building down to the last penny. This is information worth many times its cost to you. Supply of plans on this offer is limited and will not last long. Send for your set today.

For FREE information, Mark and Mail this Coupon.

Building Age Colored Perspectives

Do You Want a Set of 27?

WE have a limited number of sets of 27 each of the beautiful three and four-color perspectives, same as those used in various issues of BUILDING AGE. There has never been an opportunity for getting such a varied collection of beautiful perspectives, and as we have no remaining copies of most of the issues of BUILDING AGE in which these appeared, and as the expense of reprinting them in color—unless in very large quantities—would be prohibitive, it is probably the last opportunity of securing a set.

We have constant inquiries from subscribers for these prints separate from those bound in the magazine. Many frame them; others use them as suggestions. While they last we will send a set for one new subscription, or for renewal of your subscription for one year from date to which it is now paid; two dollars to accompany order, or enclose a dollar bill at our risk for the set.

Address orders to—

BAYONNE

Cuts
Roofing
Costs

Rising metal prices make the cost of copper roofing altogether excessive. It is not alone excessive—but entirely unnecessary.

BAYONNE

assures you of all the advantages of a copper covering and eliminates its disadvantages—contraction and expansion. This natural shortcoming of all metals causes buckling and cracking—followed by heavy repair expenses.

BAYONNE is far more economical to lay because it requires less labor and time. And once laid, it **stays flat**—does not shrink and expand, or buckle and warp. Nor does it blister, crumble and corrode like tar and other prepared coverings.

But aside from all these qualities—the one fact that it is absolutely waterproof, that it never can leak, makes it the ideal covering for roofs of porches, verandas, decks or conservatories.

Write for Sample Book "D" giving prices and laying instructions. See Sweet's, Page 426.

Herringbone Residence, Oakland, Cal. Architect, C. W. McCall

Herringbone Rigid Metal Lath

Stucco exteriors, plastered interiors, ceilings—in fact, every metal lathed job will prove more permanent when Herringbone Lath is used. Its rigidity insures ease and evenness of plastering, it grips the stucco or cement finish so firmly that cracks or falling are unknown.

Besides the economy of a job free from upkeep, Herringbone is self-furring, sheets are easily handled, interlocking edge prevents waste at side laps.

A New Complete Herringbone Lath Catalog with specifications furnished on request of—

TRADE MARK

Reg. U. S. Pat. Off.

PUT absolute certainty of roof protection into every shingle roofing job. The new Flex-A-Tile Diamond Point Slabs will bear the burden of wear and weather splendidly and help you guarantee a satisfactory job every time.

DIAMOND POINT SLABS

These new patented Flex-A-Tiles are practically four shingles in one. Their unique shape allows you to secure beautiful artistic effects and combinations hitherto unobtainable.

**Save 50% in Labor
38% in Nails
35% in Freight**

No time is wasted in chalk-lining—Diamond Point Slabs automatically space and gauge themselves; only five nails are needed for every four shingles; their shape means less weight and consequently cheaper freight.

Flex-A-Tile Quality

The same thorough, painstaking manufacturing process, the same high quality felts and asphalts, the same natural red and green slate surfacings that always have distinguished Flex-A-Tiles also distinguish Flex-A-Tile Diamond Point Slabs.

Write Us for Details

Liberal sample, prices and complete particulars gladly sent. Just say you want to know all about the new Flex-A-Tile Diamond Point Slabs.

Time Book (with Wage Tables) FREE to Contractors

Every contractor and builder will find this pocket size time book very convenient and useful.

THERE is room for twenty-two names to the page and space after each name for the checking of two weeks' time and there are sixteen time-keeping pages in the book.

More than that, it contains two very valuable sets of reference tables.

The first is a table of wages, based upon rate per day from 50c to \$7.50, worked out all the way from fifteen minutes up to 12 hours.

The other is a table for figuring the number of square yards and feet of plastering surface in several thousand size rooms.

NORTH WESTERN EXPANDED METAL COMPANY

Manufacturers of all types of Expanded Metal

904 Old Colony Building

Chicago, Ill.

For Permanency and Economy—Use Berger's Metal Building Materials

Berger's Corner Beads

Insure a smooth, round corner to which the plaster properly adheres. Prevent plaster from cracking or chipping at the corners, thereby eliminating patching, and doing away with old-fashioned wooden mould. Good for stucco work.

Berger's Rib-Trus Plates

Especially serviceable for reinforcing thin concrete slabs for roofs, floors, sidewalls and partitions. Ribs running throughout each sheet on 6-in. centers stiffen the plate and support it while the soft concrete is being applied.

Berger's Expanded Metal Lath

Adds strength and stability to a building and makes plaster go farthest. Reinforces plaster at all points, thus preventing it from cracking, breaking and falling off. The diamond-shaped meshes are small and expanded so that plaster clinches perfectly.

Berger's Ferro-Lithic Reinforcing Plates

Are used extensively for reinforcing concrete slabs for flat or arched roofs and floors, sidings of buildings, sidewalks, etc. Plate is watertight in itself, which prevents dripping of soft cement and insures a dry roof even before concrete is applied.

THIS handbook will prove valuable to all interested in reinforced concrete, as it contains illustrations, diagrams, safe load tables and complete specifications for building roofs, sidewalls, partitions and floor construction with Berger economy products. Compiled by experts—yours free for the coupon.

Please quote BUILDING AGE when writing to advertisers

Shingles and slates are not satisfactory, especially when the surface is flat or has a very slight pitch. Tin and copper corrode quickly and cannot stand continued wrenching and straining. Tarred felt and gravel become too rigid with weathering. Untreated Cotton Canvas cannot resist fungus growth.

The Best Protection Is Con-Ser-Tex

CON-SER-TEX is a cotton duck scientifically treated by a combination chemical and waterproofing process. It will not mildew nor absorb moisture. This makes fungus growths impossible. It is easy to lay and tightly adheres to the surface. With proper care it lasts as long as the house and protects it every minute. It gives the porch, the roof, the piazza, and the sleeping balcony a neat, clean, trim look. Use it to cover the garage and other out-houses.

ADVERTISE HONESTLY

—SAYS THE—

ASSOCIATION OF NATIONAL ADVERTISERS

The following Declaration of Principles was unanimously adopted by this Association, at Dayton, Ohio, May 5th, 1916:

RESOLVED that we, members of the ASSOCIATION OF NATIONAL ADVERTISERS, are opposed to advertising of the following kinds :

All advertising that is fraudulent or questionable, whether financial, medical or any other; all advertising that is indecent, vulgar or suggestive either in theme or treatment; that is "blind" or ambiguous in wording and calculated to mislead; that makes false, unwarranted or exaggerated claims; that makes uncalled for reflections on competitors or competitive goods; that makes misleading free offers; all advertising to laymen of products containing habit-forming or dangerous drugs; all advertising that makes remedial, relief or curative claims,

either directly or by inference, that are not justified by the facts or common experience; and any other advertising that may cause money loss to the reader or injury in health or morals or loss of confidence in reputable advertising and honorable business.

RESOLVED that we recognize our own obligations as advertisers to conform to these principles.

RESOLVED that we urge upon all publishers and upon all sellers of advertising space or service, a strict adherence to these principles and that in so far as the exigencies of our individual business will permit, we direct our advertising to those mediums which make the observance of these principles their rule and practice.

The Association of National Advertisers represents the leading advertisers of America. They stand as one man behind these resolutions. They are determined to do everything in their power to
**MAKE IT IMPOSSIBLE FOR THE
ADVERTISING FRAUD TO LIVE**

Distinctively, Uniformly and Perfectly Constructed

THE popularity of Berger's "Classik" Steel Ceilings is attributed to their clear, distinct and sharp-cut design, uniformity and perfect construction.

This is due to our new and original process of manufacture—Berger's "Classik" Steel Ceilings are no longer being made by the old drop hammer process, but on a specially designed draw press of 900 tons pressure.

This enormous pressure assures absolute uniformity in depth, detail and size—no variation is possible. Each plate is pressed separately and is an exact counterpart of the other.

The dies, from which these ceilings are made, are exact reproductions of skillfully clay-modeled originals, while the hundreds of artistic designs harmonize with any type of architecture.

Besides their beauty, Berger's "Classik" Steel Ceilings are fire-retardant, durable, safe, light in weight, easily and quickly erected, and reasonable in cost.

Use these ceilings in your buildings. Our "Classik" Book D. B. will help you close many contracts. Send for it.

Colonial Panel No. 4056

You Save 25 to 40 Per Cent on Every Job

Because our oval bead and countersunk nailing point construction assures a perfectly tight joint without tamping and calking.

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

National Sheet Metal Roofing Co., 339-345 Grand Street, JERSEY CITY, N. J.

Here's a Real Business Building Opportunity

Largest Manufacturers of Metal Ceilings,
Metal Shingles, Steel Roofing and Siding in

This 112 Page Roofing Catalog Is Yours Free

The *Rex Products* catalog contains 112 pages and more than 180 pictures and illustrations. Besides complete instructions for laying all styles of asphalt shingles and prepared roofings, you will find in it a full description of each one of the 27 different *Rex Products* which we manufacture. You will also find much helpful information about slate, tile, asbestos shingles, tin and corrugated steel roofings.

We will send you this splendid catalog and a set of samples without cost or obligation to you. Write—

Flintkote Manufacturing Co.

98 Pearl St., Boston, Mass.

1104 Equitable Bldg., New York, N. Y.

651 Peoples Gas Bldg., Chicago, Ill.

Hennen Bldg., New Orleans, La.

REX STRIP SHINGLES

Will not blow up in the wind because the spaces between the shingles do not extend under the shingles in the course above, and so there is no opening for the wind to get under them and lift them. This is why Rex Strip Shingles make a *tighter* roof than any individual shingles.

In two fadeless, natural slate colors—red and green. Put up in rolls 32 inches wide—103 sq. are feet in each roll; packed with nails and cement.

FLEX-A-TILE ROLL SHINGLE

(PATENTED)

WE had in mind, when we designed this new Flex-A-Tile Roll Shingle, the growing demand for asphalt shingle roofs that would cost little to lay. How nicely we have accomplished this economy is surprising—this full-size, 32-inch wide roll of asphalt shingles takes no more labor to apply than ordinary roll roofing.

IT is a splendid shingle roofing, too—satisfying perfectly the requirements of those who heretofore would never roof with commonplace roll roofings.

OF course, the illustration above cannot begin to give a realistic idea of the true beauty of the shingles—nor can it show the distinctive way each single shingle stands out without the aid of paint or any imitation process to produce the genuine appearance of individual asphalt shingles. But, let us send direct to you a sample of this Flex-A-Tile Roll Shingle. Hold it in your hand. Feel its weight. Test it any way you will.

Just Write Today

Say that you are interested in the new Flex-A-Tile Roll Roofing and mention what your business is. We will forward liberal samples, prices, and any other information you may wish.

Become An Agent

A number of excellent agency appointments for this new Flex-A-Tile Roll Shingle are still available.

When You Make A Joint Like This

THERE is a sense of pride and satisfaction when you make a joint that fits perfectly surface upon surface.

It means accurate work, accurate laying-out, accurate measurements.

Men that do this sort of work and all jobs requiring care and accuracy will find many helps among

Starrett Tools

and Instruments
of Precision

The name Starrett to cabinet makers, pattern makers and all woodworkers means accuracy, dependability and permanence.

Among the fine tools and instruments are

Scratch Gages
Dividers
Combination Squares
Steel Tapes
Try Squares
Nail Sets
Expansion Pliers
Plumb Bobs

Give Your Customers the Roof Which Imperishably Advertises You

They will probably demand a roof that is fireproof, that is wind and weather-proof. But give them more—give them the roof which will outlast the building, and always *be* as good as the day it is laid, always *look* the same, and never need one cent's worth of repairs or painting.

AMBLER
Asbestos CENTURY BRAND **Shingles**

The Roof That Is as Permanent as the Foundation

Stand the Wear and Tear

Ambler Asbestos Shingles "Century Brand" do not burn or wear out because they are built with cement and asbestos, nature's two imperishable products. The cement and asbestos fibre are built up strata by strata and then compressed under a terrific pressure that renders them mirror-smooth and free of air-holes and other surface irregularities. The asbestos fibre reinforces the cement as steel rods do a wall. Ambler Asbestos Shingles "Century Brand" are, of course, absolutely fireproof, and are also water-proof, do not warp, curl or split. They lie snug to the roof and to each other, leaving no space for rain or moisture to work through or winds to grip. They never need repairs or repainting and each shingle actually becomes stronger and tougher with exposure. Because of their medium weight, no special rafters are required. Easily and quickly laid.

There's a Style for Every Taste

Ambler Asbestos Shingles "Century Brand" are furnished and applied in a variety of styles which permit the most artistic effects. They are made in three nonfading colors: Indian Red Newport Gray and Blue Black.

Convince Yourself—It Costs Nothing

We will gladly send you full details of Ambler Asbestos Shingles "Century Brand" on request—we can only scratch the surface here. But write *NOW* for sample shingles and descriptive matter.

Weatherproof Walls

Concrete and stucco are porous. Rain and snow make a wall blotchy and unsightly. But this, the only serious drawback to the greater use of these materials, is easily overcome. Two coats of

Bay State Brick and Cement Coating

will do the trick—will absolutely weatherproof concrete, stucco, plain cement and brick. "Bay State" comes in white and a variety of attractive tints. It is for all kinds of buildings, houses, bungalows, schools, mills and factories. Also, for interiors—it "Lights Like the Sun."

This panel shows why ordinary cement absorbs water.

Sample can free—say what tint you prefer. Ask for booklet 19.

WADSWORTH, HOWLAND, & COMPANY, Inc.

Paint and Varnish Makers
BOSTON, MASS.

NEW YORK OFFICE
Architects' Bldg.

The Wall

The wall is hollow—built like a thermos bottle—perfect insulation—warm in winter—cool in summer.

The Machines

Our 1916 Flexible Sliding Plate and Angle Iron Corner System insures absolutely plumb buildings with corners of any angle—the most perfect concrete building system in the world.

The Van Guilder machines cut out one-half the labor. The steel reinforced walls cost no more completed than hollow blocks cost before they are laid.

Get the Big End of the Building Business

Think what it would mean to you if you were equipped to build concrete houses for only a little more than your competitor charges for building wooden houses. Think what it would mean to be able to do this without continually buying lumber for wood forms or having a car load of old-fashioned steel forms to take care of and move from job to job. Buy the

Van Guilder Hollow Wall Machines

A machine builds a course of hollow wall 9 inches high at each operation, using semi-wet mix. It is then moved ahead and filled again. When the job is done, you have a house within a house, the two walls being completely separated by a blanket air space. The machines have been used successfully in all parts of the country on big and little construction. It is remarkable the amount of wall you can run up in a day with the forms that you can carry on a wheelbarrow. Write for booklet containing full details.

VAN GUILDER HOLLOW WALL CO.
712 Chamber of Commerce Bldg., ROCHESTER, N. Y.

“LOCKED!”

Why are the walls of stucco finished houses so often cracked and the stucco broken off?

Because the background, through faulty construction, improper material, or insecure fastenings, breaks away from its anchorage and then the stucco, *unsupported*, cracks from its own weight and finally falls.

Bishopric Board

Will Not Corrode—Cannot Break Away or Sag

Examine well the construction. Creosoted dovetailed lath imbedded in asphalt mastic on a background of heavy fibre board—a combination of materials that possess practically everlasting wearing qualities, water-proof, weather-proof, vermin-proof and sound-proof; put together so as to form a *rigid permanent* background that *locks* the stucco so it *can't* break away.

The principles involved in its construction are as old as the pyramids, and the most efficient known today to building engineers—only the combination of those principles is modern.

OUR BOOK!
“BUILT ON THE WISDOM
OF AGES”

tells all about Bishopric Board and gives some interesting scientific tests. It illustrates homes and other buildings constructed with Bishopric Board, gives letters from builders, architects and users, and furnishes facts and figures to prove that it

Cuts the cost 25%

Why Don't You Get a Barnes Hand Circular Rip Saw?

Sawing by hand is "backbreaking" work—sawing with our machine prevents the aches, and requires no skill.

One man with a Barnes Hand Circular Rip Saw can easily rip (line measure) 600 feet of one inch pine in an hour, or 6,000 feet in 10 hours.

It will rip boards or planks of either soft or hard wood, of any thickness up to $3\frac{3}{4}$ inches and any width up to 19 inches.

Feeds slow or fast as desired; can be instantly set to or from the gauge to any width.

The Barnes is a money maker, and the price a money saver.

Send for Catalog of Wood Working Machinery

W. F. & Jno. Barnes Co.
71 Ruby Street, Rockford, Ill.

Just what you've been looking for! —a combination Hollow Chisel Mortiser and Relisher

An entirely self-contained hollow chisel mortiser, that will carry chisels up to $\frac{3}{4}$ " square and make any larger or irregular mortise by overlapping the cuts.

Easy and simple to operate. No pounding or jarring. Every mortise perfect. No chips left to be picked out by hand, when you put your work on

the other side. Relishes out the tenon and bores away for that part which goes under the mold after you have completed the work on the sash stiles, rails and muntins.

Every carpenter and jobbing shop should have one of these machines.

Up to the Wall and Into the Corners It Goes

Try This Scraper on Your Floors at Our Expense

Here's a Scraper that scrapes clean and smooth, in the corners, close up to the walls, and scrapes without those wavy lines so often caused by "chatter."

Our knife with double edge wears twice as long as any other scraper knife. Our adjustable handle, rubber tires and the way the weight is thrown on the knife are all exclusive features of the Stearns No. 10.

We don't ask you to "beware of other Scrapers," but we do ask you to accept this machine on a fifteen day **FREE TRIAL OFFER**, so you may "compare it with other Scrapers," for by test the Stearns is best.

There are fifteen days in which you can test its easy running, smooth shaving and sturdy qualities at our expense.

Write us about it.

Sold by dealers, direct from the factory or on fifteen days' trial. Particulars will interest you.

E. C. Stearns & Co.

400 Oneida St., Syracuse, N. Y., U. S. A.

Why Break Your Back?

Use the Imperial Floor Sander

No more aching knees or back. The Imperial Floor Sander makes floor surfacing easy. Simply a push and a pull and it does the work well.

Load it with twelve sheets of sandpaper. When one sheet wears out cut it off without removing the binder. Don't hesitate to tackle varnish. The Imperial will remove it; it will also resurface and wax floors.

Any carpenter can afford it. Only \$5.00. Does the work of an expensive power machine.

If your dealer doesn't handle the Imperial, we will send one direct upon the receipt of \$5.00.

Our catalog tells all about it. Send for our literature.

Hall-Holmes Manufacturing Co.

242 Oak Street, Jackson, Michigan

"The Standard"

Low-Charging Concrete Mixer

The low compact design of "The Standard" Mixer makes it unnecessary to use any kind of mechanical devices to charge the materials into the mixing drum. The mixer is charged direct by wheelbarrows by wheeling up short, slightly inclined runways on to a wide platform only 24" high. The platform is hinged so that it may be folded up against the drum at the end of the day's run or when moving from one job to another. The elimination of the side loader permits construction to be made exceptionally strong and rigid, maintaining, at the same time, light weight and portability. The mixing blades are firmly riveted to the drum and rotate with it, insuring a perfect and thorough mix at all times without slopping or spilling.

"The Standard" is built in 10 sizes with capacities ranging from 3 to 40 cu. ft. per batch. Complete Catalog No. 48-8 will be mailed upon request to our nearest office.

HOISTS

The use of Gasoline Hoists in building and a great variety of other work is rapidly increasing. Gasoline power is desirable on account of the low first cost, the small expense for attendance and operation and the light weight, enabling the outfits to be placed in the most convenient position for economical work, while handling and shipping expense is very moderate.

"The Standard" Reversible Hoist shown on the right is equipped with 6 H.P. Gasoline Engine and is recommended where an all around hoist is required.

The "SSS" Reversible Light Hoist shown on the left with 4 H.P. Gasoline Engine is for light work and where a low priced outfit is desired.

These hoists can be used for operating two platform material elevators, "The Standard" on buildings up to five or six stories and the "SSS" on buildings up to three stories.

The regular hoisting drum between the main bearings is used for single line hoisting.

Ask for Catalog No. 48-8H, describing our entire line of hoists, in all sizes and capacities, either with or without power.

Steel "Stitches" Every Few Inches

Columns which have staves simply glued together will surely open up. Columns which have any kind of a lock-joint are liable to open up. Columns which are glued under hydraulic pressure, where the staves are locked with a double V joint and sewed with cold rolled steel staples every few inches of their entire length *cannot* open up. And this is the way "Steel-Sewed" Columns are always made. Catalog explains the construction and shows many beautiful illustrations. Write for it.

AMERICAN COLUMN CO., Battle Creek, Mich.

OAK FLOORING "AMERICA'S Best Flooring"

Landlords and builders offering houses for sale or for rent command the highest of rentals and hence, the highest class of tenants. They always emphasize OAK FLOORING in their ads in newspapers.

$\frac{3}{8}$ " OAK FLOORING offers a beautiful and very economical floor at a low cost. It is the ideal flooring for laying over old floors in churches and homes. When laid, it has all the appearance of 13/16" stock. $\frac{3}{8}$ " is made in 1 1/2" face and 2" face.

Contractors and carpenters find it very profitable in soliciting the laying of $\frac{3}{8}$ " OAK FLOORING in old homes during slack periods. Any carpenter, exercising a little care, can lay OAK FLOORING successfully. 95% of modern houses now have OAK Floors. OAK FLOORING is always considered the very best kind of investment.

All reputable lumber dealers sell OAK FLOORING.

"Acme" Brand

SELECTED ¾" x 1½" Quartered White Oak FLOORING

Here is the greatest bargain ever offered in Quarter Sawed White Oak Flooring. Made of high-grade thoroughly kiln dried lumber, with modern machinery, by men who know how to make flooring that will save the carpenter many hours of hard labor in doing first-class work.

Mr. Milton Mathew, 814 Mulberry street, Marshall, Illinois, writes: "I laid some flooring last week from Chicago, and had to do twice as much work on it to get a finish as I did on the flooring I bought of you. I like that tongue and groove, it lays so easy and even."

Add one-third to the number of square feet to be covered and be convinced by sending a trial order. There is not one foot waste in a thousand feet, because it is all side and end matched. Shipments are made same day order is received, and you will find our flooring will save you many dollars.

Conservation and Efficiency— the Watchwords of this Wonderful 20th Century

And the mission and PURPOSE of the Bessler Movable Stairway is to conserve—that is to say—save space, and do it in a practical and efficient manner.

The Bessler Movable Stairway

This stairway is designed to replace the stationary stairway to attics and lofts in buildings of two stories and more. And in bungalows it provides a splendid stairway to the half-story above.

Not a single square foot of floor space is wasted in the lower room, as when the Bessler Movable Stairway is not in actual use, it is swung up into the ceiling—out of the way. Nothing is then visible in the ceiling except a neat panel finished to match the wood-work in room.

Write Us for Our Booklet

It fully describes this wonderful space saver and gives photographic views of it in various positions. At the same time we'll be glad to quote you prices.

It Is Strong and Sturdy

That fact is brought out in the picture alongside. Note the easy slope of the stairs. A child can operate it. It is fully guaranteed in every respect.

The Safety Movement has reached the home roof—meet the demand with J-M TRANSITE ASBESTOS SHINGLES

In your community, as in all others, homes are being planned to include a fire-proof roof. You should be prepared to meet this with

Johns-Manville Transite Asbestos Shingles

These shingles offer positive protection. They are more than fire-retardant—they are fireproof—and when laid American method take the base rate of insurance.

J-M Transite Asbestos Shingles never warp, shrink or split, but actually toughen with exposure and never need stain or paint.

They are examined, approved and labelled by the Underwriters' Laboratories, Inc., under the direction of the National Board of Fire Underwriters.

By filling out the registration blank accompanying every order of J-M Roofing Materials, J-M Responsibility will vouch for their satisfactory service.

Interior of Home Finished in North Carolina Pine

Your Customers Demand Interior Woodwork

There is an insistent and ever-increasing demand for paneled walls, beamed ceilings, inglenooks and other forms of interior craftsmanship.

And you must meet this demand—or overlook a most profitable outlet for your service.

North Carolina Pine

"The Wood Universal"

is most excellently adapted to interior trim. Its natural beauty and variety of grain, as well as its paint-retaining qualities, recommend it most highly for this purpose. And it is as low in price as any other wood of equal worth.

Its use will give your customer complete satisfaction. And by recommending it you earn a reputation for good business judgment and a sound knowledge of values.

Our Free Reference Book Shows Interior Finishes in Colors

A variety of the finishes possible with North Carolina Pine are shown in our new Reference Book in full colors. Send for Book B today.

DOORWAY,
ISAAC ROYALL HOUSE
at Medford, Massachusetts.
Built of White Pine in 1732.

While the Royall House as it now stands was built in 1732, a section of it—which was originally the Winthrop Farm House—was built in 1631. This is the oldest section of any house now standing in this country.

CARPENTERS, lumber men and architects have for generations agreed that no other wood gives such long and satisfactory service, when exposed to the weather, as

WHITE PINE

Despite an impression that it is scarce there is still plenty of "Good Old White Pine," in all grades, and it can be purchased in all markets at reasonable prices, when considering its value as a structural wood.

If the lumber dealers supplying the materials for those for whom you are building are at any time unable to furnish it, we would appreciate the opportunity of being helpful to you in securing it.

A FREE MAGAZINE FOR CONTRACTORS

We are now publishing a bi-monthly architectural magazine, every issue of which will be full of valuable and helpful information for contractors and builders. If you would like this magazine, write us and we will be pleased to place your name on our mailing list.

Stain Your Siding

clapboards, half-timbers, trellises, sheds and fences, as well as your shingles, with

Cabot's Creosote Stains

The soft, rich colorings are incomparably nicer than paint, and they bring out the grain of the wood in beautiful shadings. The "painty" effect spoils the beauty of the wood, and paint costs twice as much. The Stains last as long as the best paint, and "grow old gracefully"; and the creosote penetrates the wood, preserving it and making it less inflammable.

Cabot's Quilt

A genuine house-warmer. It's a cushion of dead-air spaces and is 30 times warmer than building paper. Quilt will pay for itself in a short time in saving coal, to say nothing of making the house comfortable for all time. Also a complete sound-deadener.

You can get Cabot's Stains and Quilt all over the country. Send for samples and names of nearest agents.

Section of Outside Wall of House, Showing Wool Between Studding.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

NEW YORK, AUGUST, 1916

A Shingled House in Needham, Mass.

Special Features of Construction and Arrangement Likely to Interest the Builder—Cost \$4200

THE design of the house here illustrated and described was determined by the requirements of the physician for whom it was built, the problem which the architect was called

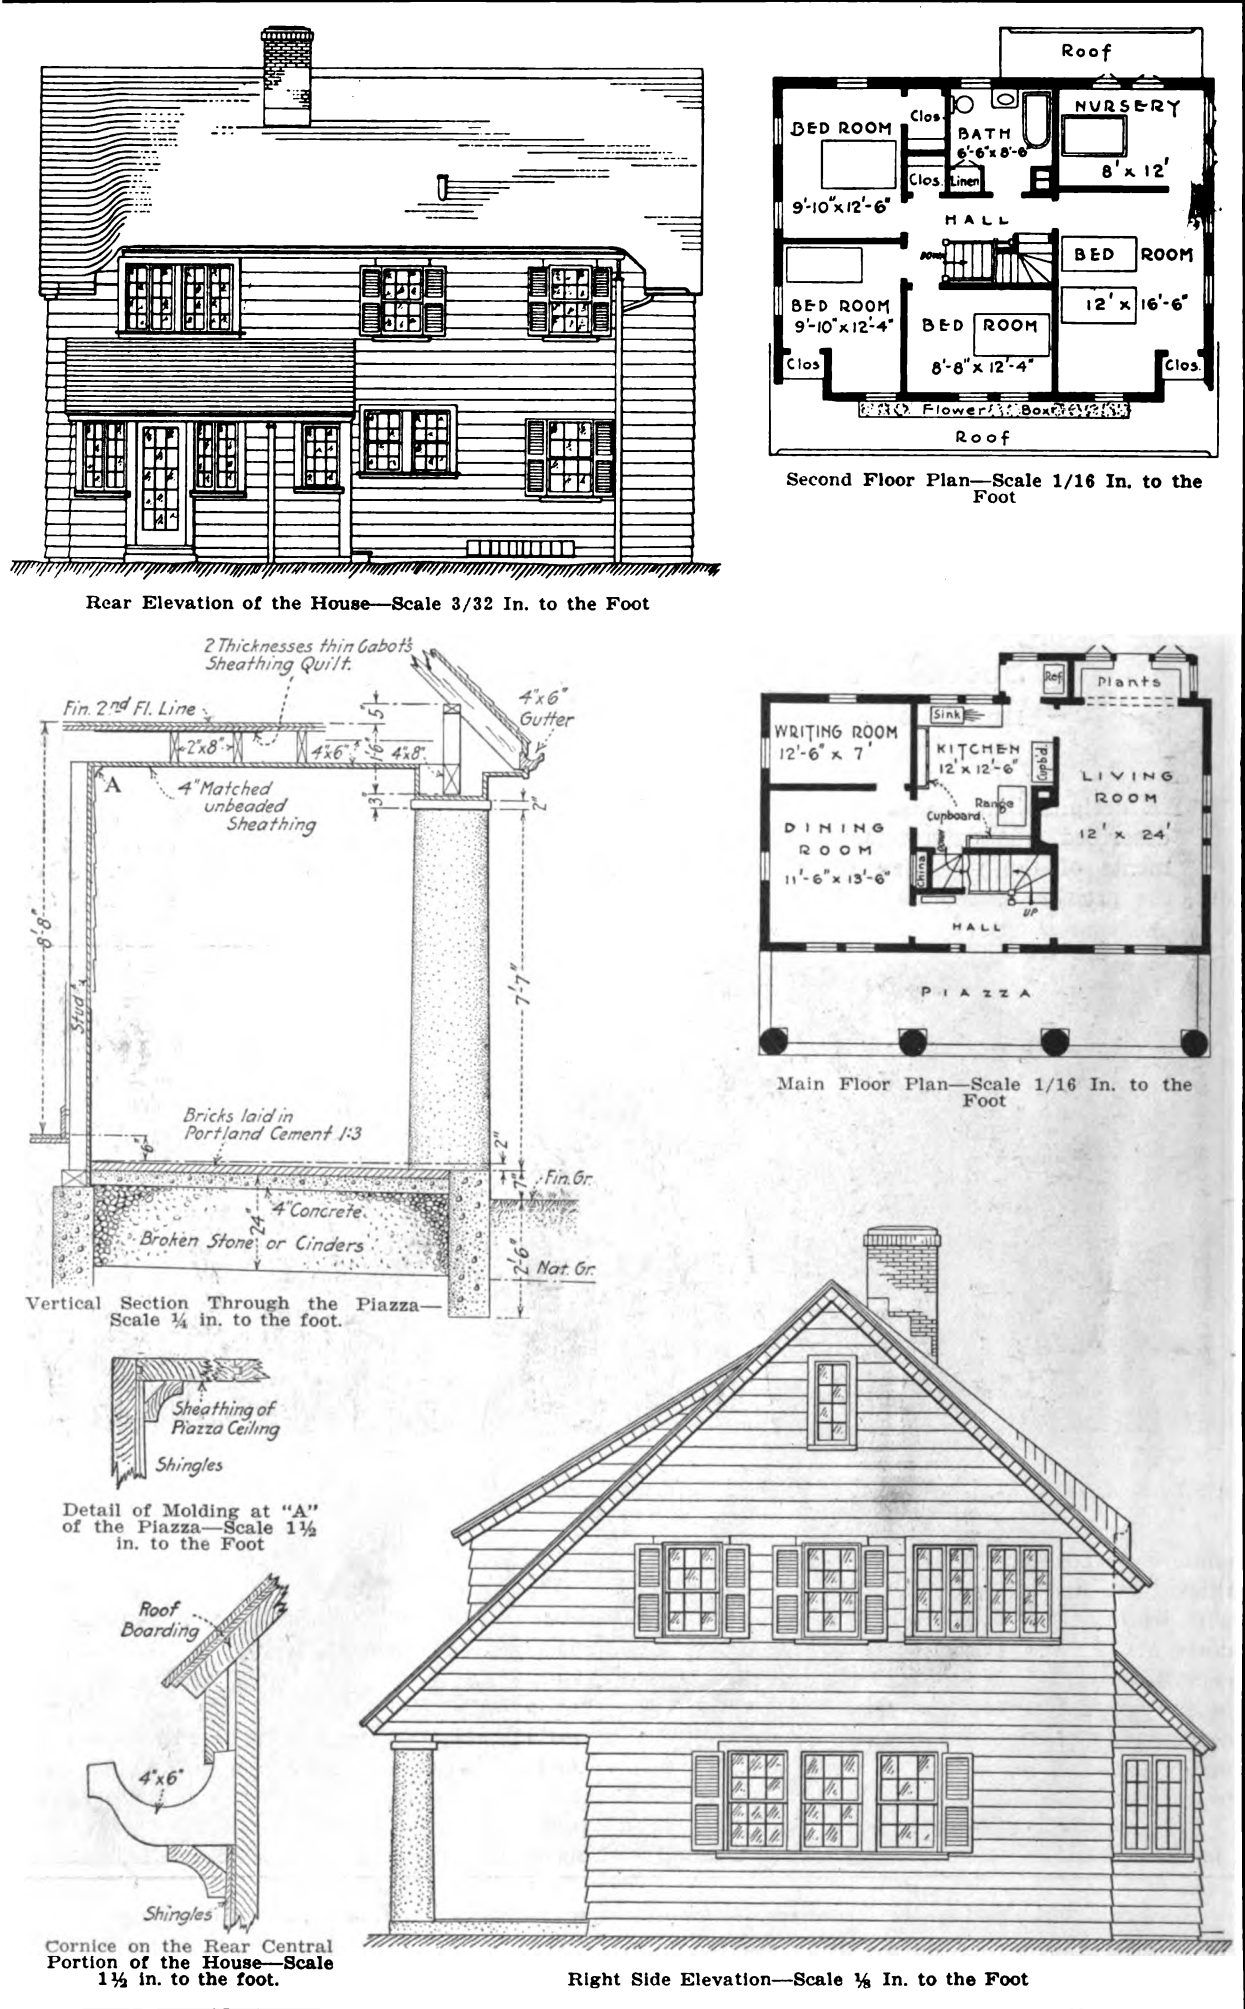

room, or both. The owner expressed a preference for cabinets or cupboards in the kitchen, rather than to have a pantry. Another factor was a large second floor plan with four or five bedrooms, bath-

A Front View of the Shingled House—Architect Edgar T. P. Walker, Hingham, Mass.

upon to solve involving among other things a relatively small first floor plan, with kitchen so placed as to serve either the living room or the dining

room and ample closet room. In a small house this was a severe problem, and as a consequence the stair hall had to be of minimum size with space

Plans, Elevations and Details of a Shingled House at Needham, Mass.

only for a hall stand on the first floor, and on the second floor ready access to each of the several rooms. The manner in which the architect solved this problem is clearly indicated in the floor plans presented on another page, while the many details afford an excellent idea of the method of construction that was pursued. The stair hall is attractively finished on both floors, the style being Old Colonial.

The exterior walls are covered with long Vancouver red shingles, combined with a finish of cypress, all painted white. The shutters and doors are painted a bright green, thus giving a pleasing contrast and making the house attractive in its external appearance.

An examination of the several halftone engravings shows a broad piazza extending across the entire front of the house, and having a brick floor set on a concrete slab resting on top of a bed of

a china closet. At the end of the dining room and lighted by two windows is the library or writing room. On the second floor are four sleeping rooms, a nursery, and a bathroom. Numerous clothes closets are provided, and opening into the bathroom is the linen closet. In the attic is sufficient space for two additional sleeping rooms, should circumstances require.

The foundation walls are of concrete mixed in the proportion of one part of Portland cement to two parts clean sharp sand and five parts of broken stone. The sills have a 1:1 cement wash, and the cellar, in which is located the laundry, has a floor of concrete 2½-in. thick resting on a bed of gravel.

The piazza floor is built of hard-burned water-struck brick, selected for color, and laid in Portland cement, the joints consisting of one part cement and three parts sand. The porch floor rests on a bed

A Shingled House at Needham, Mass.—A Photographic Perspective Showing the Immediate Surroundings

cinders surrounded by a concrete wall one foot thick. The large columns of solid concrete covered with white cement slap dashed, and the double windows at the right and left of the main entrance constitute noticeable features. The large windows in question also afford a maximum amount of light to the front rooms, and present an attractive interior aspect owing to the fact that they finish on top of the baseboard.

Referring to the floor plans it will be seen that the living room is a feature of the arrangement, extending as it does practically across the right end of the house, the rear portion terminating in what may be designated as a small conservatory or place for growing plants. At the extreme left side of the house is the dining room, communicating as already stated directly with the kitchen and provided with

2 ft. deep, consisting of broken stone or cinders.

The framing timbers are of spruce, the sills being 6 x 6 in.; the posts, 4 x 6 in.; the studs, 2 x 4 in., placed 16 in. on centers; the girts 4 x 6 in., and the door window studs, 3 x 4 in. The plates consist of two pieces of 2 x 4 in. spruce, the girders, 6 x 8 in. resting on 3½-in. Lally columns with cap and base; the first and second floor joists are 2 x 8 in., and the third floor joists, 2 x 7 in. spruce, placed 16 in. on centers; the piazza floor joists, 2 x 6 in., are also placed 16 in. on centers; the collar beams, 2 x 6 in., placed 20 in. on centers; the rafters, 2 x 8 in., placed 20 in. on centers, and the headers and trimmers, 4 x 8 in.

The outside walls and roofs of the house are covered with hemlock sheathing boards, over which on the vertical walls is one thickness of black Neponsett

Miscellaneous Constructive Details of a Shingled House at Needham, Mass.

building paper with well-lapped joints, this in turn being covered with cypress shingles laid 8 in. to the weather, the shingles on the walls having been dipped before laying. All roof surface was covered with "Extra" cedar shingles laid $4\frac{1}{2}$ in. to the weather, all shingles over 6 in. wide being split before laying. The shingles were thoroughly secured in place with zinc-coated nails made by the Malleable Iron Fitting Company.

The floor timbers are carried to the outside studing and thoroughly nailed, thus making a strong tie across the house. All floors are stiffened every six feet with herringbone cross bridging, and all door and window openings are trussed overhead. The floor joists are doubled under all unsupported partitions running parallel with the joists. The sill was painted underneath before setting it in place.

The floors of the house are double, the sub-floors

balance weights. All sash is glazed with German glass single thickness. Casement windows are provided in the conservatory and the museum.

White pine blinds with stationary slats are provided for the windows, as shown in the halftone illustrations.

The plastering consists of two-coat work, the rough coat being of No. 1 Extra Rockland lime, clean sharp sand, and the best quality long cattle hair well beaten and soaked before mixing in the proportion of $1\frac{1}{2}$ bushels of hair to each cask of lime. The skim coat is of Rockland lime, putty and beach sand troweled to a hard smooth surface. The architect states that all lime was thoroughly screened and slacked at least six days before mixing, and that no plaster was used that had not been mixed and stacked for at least three weeks.

All interior doors on the first floor, except the

A Shingled House at Needham, Mass.—A Detail of the Piazza and Dormers.

being of squared edge spruce. Under the portion of the rough floors of the rooms extending over the piazza are two thicknesses of Cabot's Sheathing Quilt.

The finish floors of the living room, dining room and halls are of oak; all other rooms having floors of heart rift Georgia pine.

The outside finish is of cypress, and the main cornice as well as the piazza cornice have stock pattern cypress gutters with all joints covered with lead. The ceiling of the piazza is of 4-in. matched unbeaded North Carolina pine sheathing. The piazza floor is of $3 \times \frac{7}{8}$ -in. hard pine.

All windows have stock frames of No. 1 white pine with pulley stiles and parting beads of hard pine. The sills are rabbeted and of 2-in. stock. All windows have $4\frac{1}{2}$ architraves. All double hung sashes are provided with Samson spot cord and

French windows and those from the kitchen to the cellar and kitchen to the rear porch, are what are known as "Korelock," made of birch and of the two-panel variety. All other inside doors, except where French windows are shown, are of the five cross-panel stock pattern fir $1\frac{1}{2}$ in. thick. The door knobs are of glass. The outside front door is of white pine $2\frac{1}{4}$ in. thick and paneled as shown in the details presented on another page. The French windows are of $2\frac{1}{4}$ -in. birch. The outside door frames are of white pine double rabbeted with 2-in. rabbeted hard pine sills.

The interior finish throughout is of North Carolina pine painted white, the architraves being $\frac{7}{8} \times 4\frac{1}{2}$ in. plain for all jambs, and the headers 1×5 in., the head projecting $\frac{1}{8}$ in. beyond the jambs. There are no corner blocks but simple plinth blocks at the doors. The architraves in the kitchen

are $4\frac{1}{2} \times 7\frac{3}{8}$ in. plain rounded corners with butt joints. All rooms have $\frac{7}{8} \times 6$ in. base with no molding. The dining room and living room bases are 7 in. high from the finish floor. These two rooms also have a wood cornice. The dining room has a white wainscot with painted canvas under the chair rail. The house both inside and outside with the exception of the kitchen and entry is painted white.

The fireplace in the living room is of dark red

Mass., were the contractors and did the carpentry and masonry work, the brick floor for the piazza, the concrete and plaster work, as well as the interior finish, for \$3,170, their work making the house complete, except for the heating, plumbing, painting and electric lighting. The owner looked after the installation of the electric lights and directed all the painting. The hot water heating system was installed by John Gegenheimer of Needham,

Miscellaneous Constructive Details of a Shingled House at Needham, Mass.

waterstruck brick, laid in cement mortar, the face of the fireplace being of old Dutch tiles.

The bathroom is provided with the usual open type fixtures, with medicine cabinet set between the studs and mirror in the door.

The house here illustrated and described was erected in Needham, Mass., in accordance with plans and specifications prepared by Architect Edgar T. P. Walker, with offices at Hingham, Mass.

Nickerson & Scarr, 10 Pearl Street, Dorchester,

Mass., for \$380, and the plumbing with open fixtures for \$324.

Pacific Coast Building Operations

Our San Francisco correspondent, writing under date of July 1, in regard to the building situation on the Pacific coast, says:

Longshoremen, deckhands, and other workmen employed in handling cargo on the coastwise and

river steamers along the Pacific coast went on strike several weeks ago, with the result that the building business in the Pacific States, and in the San Francisco district especially, is very badly handicapped. The effect is seen in the official records for the week ending June 24, when the valuation of building contracts filed with the County Recorder fell lower than for any other week since 1906, and very few new permits were issued during the latter part of the month.

The reason is that most of the lumber used in San Francisco is brought in by steamer from the Columbia River, Puget Sound, or from the Humboldt redwood district, and the supply has been practically cut off. For some time it was impossible for contractors to get any lumber, lath or shingles at all, as the lumber yards all stood out against the union demands and the yard workmen would handle nothing that was unloaded by strike-breakers. As a result most of the carpen-

concerns that have agreed to the union terms.

The interior towns have had little trouble, as most of their lumber comes from the Willamette Valley and Sierra Mountain mills by rail.

Work was recently started on the long-projected office building of the Southern Pacific Railroad near the foot of Market Street, San Francisco, when men began driving piles for the foundation. The piles driven are 135 ft. long—said to be the longest ever used for foundation work in this city—owing to the ground, formerly tide land, having been filled in. The building, of Class A construction, will have a frontage on the south side of Market Street of 275 ft., the full distance between Spear and Stewart Streets. It will be ten stories high, with provision for additional stories, and will cost about \$1,250,000. Bliss & Faville are the architects.

A regiment composed of building contractors and mechanics, architects, material

View Looking the Length of the Piazza

View in the Living Room of the Shingled House at Needham, Mass., Looking Toward the Open Fire Place Showing Bookcase at the Right and Casement Window at the Extreme Left

ters in the city have been idle, as well as plasterers and others whose work depends on that of the carpenter, and conditions have not been much better at most of the bay towns. At first the strike was expected to end quickly, but it has dragged out for several weeks, with no end in sight yet, and the situation has not been much relieved by the few

dealers, etc., is being organized to take part in the great Preparedness Parade to be held in San Francisco July 22, the work of organization being directed by State Senator W. S. Scott. Enrollments have come in rapidly, and the plan is to form a permanent organization that could be used in case of military necessity.

The Portland Cement Industry

The first half of 1916 has been a busy period for the Portland cement industry in most parts of the United States. Labor troubles have caused the temporary shutting down of a few plants in Illinois, and the business ordinarily taken care of by these plants has gone to others in the Central States, but none have been reported as having voluntarily closed in 1916.

The opening of a new cement plant nowadays, when the country is so well dotted with plants, is an event of importance, and the fact that two new ones have begun operations is of considerable interest. Both of them are in the Middle West, one at its extreme north, at New Duluth, Minn., the other at its extreme south, at Houston, Tex.

In 1914 and 1915 there was a decrease in the production of cement, consumers exercising strict economy in its use, but the year 1916 shows a reaction, having opened with a demand unprecedented for a midwinter season. Prices, which had averaged only 86 cents a barrel for the entire year 1915, began to rise toward the end of that year and in the Eastern and Middle States, where cement sold at 70 to 90 cents a barrel, they continued to rise in 1916 until, in June, they ranged from \$1.10 to \$1.25 a barrel. The increased prices, of course, do not mean an equivalent net increase in returns to the manufacturers, for the costs of explosives for blasting and of coal have both risen, and laborers are in many places demanding an increase in wages. These comparatively high prices have not, however, checked the demand for cement. Many manufacturers are selling all they can produce, and others are even drawing on stocks so as to fill orders promptly.

Although no statistics have been reported to the United States Geological Survey at this date, it is believed that the total output of Portland cement for the first half of 1916 has considerably exceeded that for the corresponding period of 1915. In general an optimistic feeling prevails among manufacturers, and it is confidently predicted that the year will show a gain over 1915, both in production and shipments of Portland cement. Moreover, there is a fair possibility that they will exceed those of 1913 and thus establish a new record.

Fillers for Cracks in Floors

Now that the use of rugs on painted or varnished floors has become almost universal, the painter is frequently called upon to fix up an old floor to prepare it for painting or staining. One of the most difficult parts of the problem is that of filling up the wide cracks that have been caused by the shrinkage of the wood, so that the filler will "stay put." Various crack fillers have been put upon the market, and some of them are quite satisfactory and may be used by the painter with the assurance that if directions are carefully followed, the results will be pleasing to his customers, but it is not always possible to obtain these prepared materials at the local dealer's store at the time they are wanted, and the quantity required for a single

floor is usually too small to send a special order to the distant manufacturer or jobber. Therefore, says a recent issue of the *Painters Magazine*, we feel that a few recipes for crack fillers that can be prepared by the painter, and which are said to be satisfactory, will be appreciated.

The following method is given by H. B. Brewster, a well-known master painter of Newark, N. J., as one that he has always found to give perfect satisfaction and which will stand hard usage without loosening from the cracks. He takes a cheap varnish and stirs in plaster of paris gradually, until it gets to the consistency of putty. For small cracks he does not make it as stiff as he would for the wider ones. He cautions against putting either turpentine or dryer into the filler—just varnish and plaster, nothing else. The material is worked just like putty and pressed into the cracks in the same manner as putty. It is much slower drying than plaster and may be kept soft for some time if kept in a sealed can. While he says that he uses cheap varnish in making this crack filler, better results would probably be obtained from the employment of a fairly good varnish.

The Floor Should Be Well Cleaned

In using the above, or any other crack filler, it is important first to thoroughly scour the floor and allow it to become perfectly dry, and to clean the cracks entirely free from dirt, otherwise there is likelihood of grease adhering to the sides of the cracks, which may prevent the filler from firmly adhering.

A good linseed oil and whiting putty may be used as a crack filler and this is improved by adding to it some dry white lead. Enough raw sienna or other coloring matter to make it match the floor should be employed where the floor is to be stained and varnished. For painted floors it will not be necessary to color the filler.

The filler must be pressed down firmly into the cracks, smoothed down by wetting the putty knife with turpentine and allowed to dry hard and firm, when the surface should be sandpapered.

Before using any putty mixture in filling cracks it is well to give them a coating of linseed oil. Boiled oil is recommended by some practical men.

For filling cracks wider than a quarter of an inch the following has been recommended:—Use a mixture of glue size, whiting and fine sawdust, with enough coloring matter to tint it to match the floor boards, made into a putty-like mass and applied in the same manner as ordinary putty.

A Good Filler from Blotting Paper

Another method that is said to be good is to soak blotting paper in water until it can be squeezed out and kneaded into a fairly stiff mass with glue size and whiting. This, also, should be colored to match the floor boards. It is claimed that none of these fillers will shrink if pressed down firmly into the cracks and permitted to harden.

Another formula consists of a mixture of whiting and glazier's putty, to which blotting paper soaked in water is added, and the whole mass well kneaded together with some brown japan and a little turpentine well pressed into the joints with an ordinary putty knife.

A Modern Barn for the Dairy Farm

Side Walls of Tile with Gable Ends of Frame Construction and a Self-Supporting Arched Roof

By W. E. FRUDDEN

THE subject of barn construction and arrangement is one of never-ending interest to the builder doing work in the farming sections of the country, and the design which is here presented involves features which are likely to attract more than passing attention. This large, roomy and conveniently arranged dairy barn is located in Pocahontas County, Iowa, this being probably the biggest farming State in the Union.

The structure, strictly speaking, is a dairy barn arranged with factory efficiency. Forty cow stalls, a large calf pen, two feed rooms with grain bins over head and over 100 tons loose hay have been

comfort and general sanitation throughout, the results, practical dairymen generally know, are more profits in the milk pail.

The barn is of tile construction with walls 8 in. thick, while the footings as well as the floors throughout are of concrete. The gable ends are of frame and the arched roof is self-supporting, thus affording plenty of unobstructed hay room in the mow. Many interesting details necessary for the enlightenment of the builder are shown on another page.

Cold and damp concrete floors have been said to cause rheumatism in cattle, but to prevent this the

A Corner of the Barn with the Hollow Tile Crib and Hog House in the Central Background

provided for in this 40 x 100 ft. building. The cattle face the center feed alley. There are 20 stalls and stanchions on each side of the barn and the calf pen and the feed rooms are located at the end of the building. The whole barn is light and airy and a spick-and-span condition rules. Not only are the cows given a comfortable home, but the milkers and the men who do the chores are contented. The greatest drawback with the dairy business to-day is the labor problem, but the man whose farm is supplied with a milk-producing factory like that here shown will have this perplexing problem solved to a large extent. With contented labor and cow

stall floors are covered with cork brick as an insulator. All the steel stall partitions and the stanchions are strong and durable, affording the least possible resistance to the circulation of the fresh air about the barn. The 4-in. pipe columns which support the hay-floor girders are in the same line with the stanchions.

The hay-floor joists are 12 in. and are set 2 ft. on centers, being supported at the center by two girders built up with four 12-in. planks. The joists are lapped at the center or tied with a cleat and are bonded to the walls.

The rafters are 2 x 6 in. placed 2 ft. on centers.

The roof arches were built up complete on the ground and were then hoisted into position. The hip bracing is shown in one of the accompanying details. This, as might naturally be supposed, must be solid and well spiked together. The lower end of the roof arches is also well spiked to the double wall plate, which is anchored to the clay tile walls every 6 feet. The tile walls and the roof are securely tied to the floor joists by a system of bracing, the details of which are here illustrated. The

cows and is 6 ft. 4 in. in width, thus affording plenty of room for the men doing the chores. The gutter is 18 in., and for large Holstein cattle, such as are bred on the County farm, a 5-ft. stall is needed. For Jerseys or some of the smaller breeds a 4½-ft. stall would be satisfactory. The concrete mangers are 30 in. wide and the feed alley running through the center of the building is 8 ft. wide, thus giving sufficient width to enable teams to be driven through the entire length of the barn. One

Floor Plan and Details of a Modern Barn for the Dairy Farm

brace system is located opposite each floor-supporting column, the columns being placed not more than 10½ ft. apart in the length of the barn. The hay floor is covered with shiplap flooring. The roof is covered with sheathing boards and cedar shingles. An examination of the accompanying floor plan shows the position of the little alley back of the

of the pictures presented herewith is a view looking down the center feed alley. The floor plan also clearly shows the position of the carrier track, as well as of the two hay chutes. As will be seen from another picture accompanying this article, the barn is of attractive appearance, and may well be termed "a modern structure for

the dairy farm." The use of hollow tile has won great favor in all parts of Iowa, and there is hardly a farm in the State that is more than 50 miles from a clay products plant. The tile is secured at a reasonable price and the resulting buildings are very

the prominent architects, the men for whom you would like to estimate? Are you in a position to select the good prospects and avoid the poor ones? In a word, are you competing against men who do the same caliber of work that you are doing, or are you forced out of your class because you are not on the chosen lists? If you cannot answer these questions to your entire satisfaction, then you are ready for serious thought on the question of advertising.

A Modern Barn for the Dairy Farm—A Side View with Crib and Hog House at the Left

satisfactory. The tile walls are impervious to moisture, warm and dry in winter and cool in summer.

How the Building Contractor Can Advertise and Obtain Results

"How can a general contractor advertise?"

Which, of course, means how can he obtain the right kind of publicity; the kind that will do more than fill advertising space and cost money—in a word, the kind that pulls?

The principles of advertising are the same whether you are endeavoring to sell books, bricks, or office buildings or seeking to get your name on the architects' lists, says a writer in an exchange. The only things that change are the manner and methods of publicity. A general contractor must therefore adopt methods suitable to his own particular business, which, by the way, is decidedly different from any other type of business, and must have its advertising done and copy written by men who understand, in a most comprehensive manner, the details and intricacies of the building trade.

Then, again, the advertising must be of a twofold nature, inasmuch as its appeal must reach both architects and owners—two different types of men, and in most cases with very little in common so far as their training is concerned.

To the architect, the builder's advertisement must appeal with such riveting force as to be ever before him. If not in a physical manner, at least mentally it must make a little dent in his mind and "ring the bell" at the psychological moment when the architect is making up his list of bidders, and the nearer the top of the list the better his chance of always being among the favored few.

You (Mr. Builder) may say that you already do enough estimating and are now working overtime trying to land jobs. Are you on the lists of all of

stucco. No sheathing is used, the lath being applied directly to the studding and plastered on both sides. Three coats are used on the outside and one on the inside of the lath. The first coat is usually about one-half inch thick, the second the same, and the same thickness is used for the back plaster. The finishing coat on the exterior is about one-quarter inch thick. This gives an exterior wall covering $1\frac{3}{4}$ in. thick with the metal lath so imbedded that the wall is practically a reinforced concrete slab.

A Miniature Steel Frame Commercial Building

What is said to be the smallest steel commercial building in the country is in course of erection on a triangular site, a fraction of a lot, at the southeast corner of Broadway and 129th Street, New York City. It will be known as the midget. Three stories high, it will front 27.7 ft. on Broadway, 14.4 ft. on 129th Street and 31.4 ft. on the rear line.

There will be a store on the street level and offices

A View Looking Down the Center Feed Alley Showing Stanchions at Right and Left

on the two upper floors. As it is necessary to utilize every inch of floor space, glass windows and doors will be placed flush with the building line.

The staircase leading from the street to the roof will be 2 ft. in the clear. That it might not occupy too much of the lot, it was necessary to make the

floor heights conform with the risers in the staircase. Comparatively speaking, the stairs will be nearly as perpendicular as a ladder. Wash room

alignment of streets in the Manhattanville section made years ago. Big tenements adjoin the property to the east. Because of its small dimensions build-

Miscellaneous Constructive Details of a Modern Barn for the Dairy Farm

facilities are to be on the roof and in the basement.

The building is estimated by the architects, H. Craig Severance and William Van Allen, to cost \$6000. The gore is the result of changes in the

ers had no use for the gore, neither did adjoining owners, who thought that since no use had been made of the parcel the gore would serve to protect the light of their flats.

New Ideas About Concrete Floors*

Advantages and Manner of Laying—Adaptability to Ground Floor When There Is No Cellar

WHY do most people dislike concrete floors? Partly because we are all slaves to habit, partly because concrete floors are not what they really ought to be.

Twenty years ago I built for myself a concrete floor. I expected it to be cold. I expected it to be damp. I expected it to be all the uncomfortable things people said it would be. I found it warm and dry and all the comfortable things people had not said it would be. Best of all, I knew it would never harbor the vermin of sorts that infest old wooden flooring, mice that scamper at night, or the accidental cat.

The charges against the concrete floor are precisely those made years ago against the concrete sidewalk. We had come from dirt paths where feet find comfort in the happy medium between dust and mud, and the board sidewalk with its awkward surprises of heel-trapping cracks, loose nails and broken boards, to the smooth, hard, level cement. At first the rut-lovers wailed. But who would now go back to uneven board walks or the pleasant uncertain earth paths? In foreign lands where the cement walk is unknown, who does not pray long and loud for its revelation to all the world?

The Earth Floor

Perhaps the earth floor is the ideal thing, but we have passed that stage, and in the evolution of house-building the wood floor is finding a rival. Wood floors above ground without a basement are unhealthful. There is always a musty odor from the poisonous fungus growing on the wood and on the ground. The ground underneath an old house is poisonous to such an extent that plants will not grow in it. The soil from under a cement sidewalk is very fertile.

Most concrete floors have not yet been developed beyond the sidewalk stage. If half the thought and time and money had been expended on perfecting the concrete floor that has been spent on developing wood from the rough board sidewalk to fine parquetry flooring, everybody would want the concrete.

Architect Should Overcome Popular Prejudice

To overcome the popular prejudice against concrete floors is the business of the architect. There are certain definite conditions to be observed in the laying of concrete floors. They are fundamental and in their strict observance lies the answer to the charge of the physical discomfort of concrete. After practical objections are overcome, attention may be given to esthetic considerations.

Concrete floors are usually laid free from the ground, with a dead air space underneath. In most of my houses the concrete floors are laid directly

on the ground, doing away with air circulation under the floor and giving a more equal temperature. They are raised at least 21 in. above the surrounding ground, and particular attention paid to the preparation of the earth bed. After the foundation is laid the ground is puddled and tamped until very firm. Over the surface is spread from 4 to 6 in. of sand or sandy loam. Then the concrete is put on. If one part of the floor is below grade, the ground under it is carefully drained, after which the layer of sand prevents moisture from coming through.

Reinforce the Concrete

The main body of rough concrete should be reinforced to 1/3 of 1 per cent to prevent cracking, and scored to give a key to the top coat, and prevent its loosening from the bottom. The finish coat should be reinforced with No. 18 gauge half-inch mesh galvanized wire to prevent cracking.

From four to six weeks should be allowed for cement floors to dry. During this time there is a continuous process of absorption and radiation of heat until a mean temperature has been reached, after which the temperature of the floor is more equable than that of wood.

To cover a cement floor with wood is about as logical as to cover cement sidewalks with boards. Everybody who has lived on cement floors laid according to the given specifications has been wholly converted to them and would never again be bothered with the care and trials of wood floors. It is not, of course, expected that concrete floors should be left bare. They should be partly covered with rugs, the same as a polished wood floor. Incidentally, when properly laid, waxed and polished, cement floors are ideal for dancing.

When Cement Floors Do Not Scratch

When troweled and finished to a gloss, cement floors do not mar nor scratch. They should not be scored or marked off into squares or designs. The natural crazing of the top coat is far more pleasing. I have found no cement floor paint that produces a good effect. The hard monotonous flat colors are unpleasing, the paint soon wears off and shows the cement. Instead of using paint, I mix color with cement, usually tones of red and yellow, red and brown or yellow and brown slightly mottled. Tempered by the gray of the cement, these colors produce neutral tones that are a splendid background for rugs and furniture. When quite dry, the cement should be cleaned with a weak solution of ammonia and water, given two coats of Chinese nut oil to bring out the color, then finished with a filler and waxed like hardwood. Well done, this treatment gives an effect of old Spanish leather.

It is quite as impossible to tell how to lay a cement floor to bring out all its potential beauty as

*Reprint from an article by Irving J. Gill, architect, in *Sunset Magazine*.

Selecting Woods for Interior Finish

Classes and Varieties—Characteristics and Uses of Woods—Those Most Suitable for Interior Trim

BY JOHN S. EDMUND

IN the selection of the kind of woods to use for the interior finish or woodwork of a home, great care should be taken. The woodwork of the various rooms must be permanently satisfying, and help to make the surroundings homelike and comfortable. There is pleasure in possessing beautiful woodwork, as it gives refinement to the home and is the keynote for the rest of the fittings. The object in finishing woods by the various methods is not only to preserve them, but to bring out their wonderful beauty, thus developing the beautiful and irregular markings produced by nature. Nature has outlined the grain of wood with peculiar markings, some very faint and others more pronounced.

There are any number of our native woods which are used for interior woodwork, each having an individual beauty, color, sturdy texture and grain of its own.

Woods may be divided into two classes, namely; hard woods, which are both open and close grained; soft woods, which woods are invariably close grained. The hard woods that are most generally used for interior woodwork are as follows: Oak, ash, chestnut, birch and cherry. Soft woods: Pine, cypress, red gum, poplar and white wood.

There are two reasons why our native woods are used to such a great extent to cover almost all the wall and ceiling area of the various rooms of the home, first because the woods are easy to obtain, and second, owing to the fact that they are comparatively inexpensive.

In the selection of a wood for the living room, library, hall or dining room, we should use one which has a decided marking or grain and a strong fiber. The woods which would be suitable are oak, gum chestnut or cypress. For bedrooms, sewing room or the like, the woods of a finer texture and less decided grain would be proper. For the kitchen, laundry or bath where the woodwork is subjected to both heat and dampness, cypress and white pine are much to be preferred, for it is well known they shrink, swell or warp but little.

We should be careful in specifying the wood, whether it is to be plain sawn or quarter sawn, as this will make a great difference both in the beauty, adaptation to their various uses and cost.

Quarter sawn oak is the best for interior woodwork, as it develops beautiful figures in the wood, is much finer in grain, has a stronger fiber or texture and is most interesting. When plain sawn the texture is much coarser and the wood is not so beautiful.

Chestnut when quarter sawn is just the opposite to oak, for it loses its beauty and interest,

but when plain sawn is one of the most beautiful woods for interior woodwork available and is not quite so expensive as oak.

The markings of Southern pine are very beautiful and interesting when plain sawn and where the woodwork will not receive very hard wear is greatly desired for interior trim. For flooring, quarter sawn Southern pine, commonly called comb grained, is used to a great extent owing to its good wearing qualities, as it resists wear very successfully.

Selecting Woods for Interior Finish—An Excellent Example of Stair and Panel Work

Chestnut is perhaps the most generally desired wood for interior woodwork. One reason for this is that there is perhaps a greater variety in the grain of chestnut than is to be found in any other wood. It has a wonderfully interesting color quality and lends itself to color treatment with readiness which gives delightful effects. It does not naturally incline to warp or check, works easy and stands well, so is to be desired for interior woodwork.

There are many varieties of oak, those mostly used being white and red oak, either of which are preferred when quarter sawn. Oak is one of the best woods for every purpose, especially for interior finishing and floors. The wood of the white oak is of a light straw color and that of the red oak has a reddish tinge, so that they cannot be used together for interior trim. Either wood answers practically as well if kept separate.

Birch and cherry are adapted to an endless variety

Selecting Woods for Interior Finish—Another Staircase Showing a Little Different Treatment

of finishes, and when properly treated, very beautiful results can be obtained. They are very often used to imitate mahogany. Both woods are very hard, heavy and of a fine texture and are particularly suited for moldings and fine woodwork, as they cannot be obtained in very wide boards.

Almost all the maple used in building comes from the sugar maple tree. The wood is heavy, hard, of a fine texture and often has a wavy grain known as curly. The wood is of a creamy white in color and works and stands well. The curly or bird's-eye maple is one of the most beautiful of our hard woods, and at present is used extensively for fine interior finishing. Some of the handsomest chambers are finished in bird's-eye maple.

Ash is used to a great extent and is gaining in favor for interior woodwork. It has a beautiful close grain, considerable less marking than chest-

nut, is heavy and stands well. Ash is the cheapest of hard woods and is much easier to work than oak.

Poplar or white wood used very often to imitate some of the more costly woods, such as cherry, is of a fine texture, creamy white in color and can be secured in very wide boards free from knots. There is considerable grain in the soft woods which, if brought out, is very handsome. Some very beautiful and decorative effects can be obtained from these woods if they are developed properly.

At the present time the most extensively used soft wood for interior trim is cypress. This wood, like maple, very often has a curly grain. The color varies from a light to a dark brown. It can be secured in very wide boards, and because it has no natural tendencies to shrink or swell, it is used to a great extent for paneling.

Red gum wood is also used for interior trim. The wood is rather soft and is commonly cross-grained, but of a very fine texture. It is a very handsome wood, and shows at its best perhaps when it is quarter sawn. When plain sawn it is not so good, owing to its tendency to warp.

Simple Test for Porosity of Brick

A simple test for brick porosity consists of holding the tongue lightly in contact with the brick, says a writer in the *London Building World*. If a distinct suction is felt the brick will be very porous. If no appreciable suction is apparent but the moisture rapidly dries from the surface of the brick, it is but slightly porous.

Bricks made by the semi-dry process—that is, by compressing the clay in the form of a damp dust—absorbs only about 5 per cent of water, though they vary greatly in this respect. Engineering brick absorb less than 1 per cent of their weight of water. For all ordinary purposes, therefore, it is not desirable to designate bricks which absorb less than 15 per cent of their weight of water, on immersion, as particularly porous.

During the last few years the use of hollow blocks and hollow bricks has extended rapidly. These are much lighter than solid bricks and effect an important saving in railway carriage, but they must be distinguished from porous bricks. The weight alone is not a sufficient guide, as hollow bricks are now made which are indistinguishable in appearance from solid bricks. When cut or broken their hollowness is easily seen. On the continent porous bricks are defined as having a weight which is notably less than common bricks, but this definition will have to be abandoned now that hollow bricks are made in large numbers.

The large hollow bricks used in fireproof floors, etc., are usually made of highly porous material. This not only reduces the cost of carriage and the weight of material in the structure, but it facilitates the manufacture of bricks accurate in shape and free from twists.

The Forest Service states that approximately 330,000 cords of wood waste of a value of \$1,400,000 were utilized in 1914 by thirty-five of the two hundred pulp and paper mills of the United States.

Door and Window Treatment as Exemplified by Main Entrance to an Apartment House in Chicago

Two Entrance Doorways Which Present Striking Contrasts in Their Detailed Treatment Yet Retain Features of Similarity in Their General Design

Designs of Modern Door Knockers, Handles, Etc.—Photographs Courtesy of Russell & Erwin Mfg. Co.

Fig. 2—An Interior Where the Decorative Strips of Paneling and the Woodwork Match the Furniture

the furniture, in line and general style. Thus one more step is advanced in the direction of attaining an ideal decoration. An unusually good example of this is shown in Fig. 2 of the accompanying illustrations. Note the beams on the ceiling particularly; also the decorative strips of the wainscot of grained wall board. Both are in perfect keeping with the neat furniture and other woodwork.

Wall board bungalow interiors not only make possible unrivaled decorative treatment, but satisfy the demands of well-built walls and ceilings as well. And as expressions of individual taste they are highly desirable, as is evident in Figs. 1, 3, 4 and 5.

The extent to which one's ideals may be carried out to actuality with wall board is shown in Fig. 1.

Use of Wall Board in the Bungalow—Fig. 3—Another Interior Where the Board is Used to Good Effect

Fig. 4—An Attractive Interior Showing the Striking Effects That May Be Obtained With Wall Board

True, it is extreme, but attractive, nevertheless. In Fig. 3 is shown a ceiling treatment common to summer cottages; it is, however, adapted to the bungalow, particularly where a simple rustic decoration is sought. Two attractive bungalow rooms are illustrated in Figs. 4 and 5.

Most bungalows have large attics which cannot be utilized for living accommodations on account of being close under the roof, where the stifling heat of the sun in summer has easy access. The

fact that this attic space is practically wasted is the real reason why bungalows, as a rule, are more costly than the regular dwelling for the same habitable space.

Now, by finishing the attic, perhaps putting several bedrooms in it, not only is the cost of the building greatly reduced, but its value is also thereby increased, and wall board is just the thing for attic rooms. Its well-known non-conductivity of heat prevents the sun's heat from penetrating

Use of Wall Board in the Bungalow—Fig. 5—A Decorative Frieze Above the Panelling of the Walls

into the rooms, which means comfortable rooms. Being easily cut with a saw or knife, the board can be readily fitted into the many nooks and corners found in every attic. It can be readily applied directly to the roof rafters. Most important, though, is the fact that it is clean to handle and put up. How many home-owners have given up the idea of finishing their attics, or are hesitating to do so, because of the dread of the muss, litter and inconvenience that always accompanies lath and plaster work? Wall board removes this drawback.

Sight must not be lost, however, of the other advantages of wall board when considering those that make it particularly suited to bungalows. It is easy to apply, and when once on, the decoration can begin immediately. There is no long delay as is necessary when plaster is used. It is durable, will not chip or crack. Rooms finished with it are

of its many uses, portability and comparatively low initial and maintenance cost. A man who has found an equipment of this character indispensable in the successful conduct of a business amounting annually to about \$20,000 is George W. Leiter, a carpenter and builder in Buchanan, Mich. As shown in the illustration, which represents an interior view of his shop, the saw rig is set up near the center of the floor and occupies very little space.

The building in which it is housed is a brick structure measuring 24 x 45 ft., being well lighted by large windows on each long side and at either end. The shop has sufficient dimensions to accommodate a plentiful supply of lumber, which is kept where most convenient to the workmen. On the far side of the room is seen a workbench, located beneath the windows, thus giving the carpenter plenty of light for his operations. The saw rig is located about the center of the shop, so that no

Interior View of Carpenter Shop of George W. Leiter at Buchanan, Mich.—Showing Motor Driven Saw Rig.

attractive and sanitary. By using a good oil paint to decorate it a damp cloth will readily cleanse it. There are many more reasons for using wall board, but what have been given are no doubt sufficient to convince even the most skeptical.

A Well Equipped Carpenter Shop

It is a well-known fact that carpenters and builders throughout the country are daily realizing that in the long run it is profitable to purchase mechanical equipment capable of facilitating production and reducing construction costs. The concrete mixer has enjoyed a remarkable growth in recent years and the woodworking machinery field has seen a steady increase in the marketing and selling of numerous labor-saving devices. One of the most popular models in this line is the saw rig, because

time is lost in carrying materials to and from the machine to the bench. The rig is operated by a 2-hp. electric motor, which the owner prefers to a gasoline engine. Mr. Leiter purchased the equipment from the Oshkosh Mfg. Co., Oshkosh, Wis., and when occasion requires the saw rig is taken out on the job, as was the case recently when Mr. Leiter took the contract for carpentry work on a new foundry in Buchanan. For supervising the progress of work and for carrying lumber, tools, etc., Mr. Leiter utilized a Ford car with a truck arrangement in the form of a large box at the rear. The truck has been built to carry 800 lb. without any trouble, and has been used successfully for five years. Particular advantages are found with this class of truck because of the fact that it may be converted into a pleasure car at any time, while in either case the cost of operation and maintenance is very low, comparatively speaking.

Five-Room Bungalow of Moderate Cost

Our Supplemental Plate Design Well Adapted
for the Suburbs, the Lakeside or the Seashore

WE have taken, as the subject for our supplemental plate this month, a design of bungalow with five rooms which is likely to appeal to prospective builders in all parts of the country. According to the specifications of the architect, all footings, walls and piers are to be of concrete, mixed in the proportion of one part Portland cement, three parts sand and four parts broken stone of a size to pass through a 2-in. ring. A 3-in. tile drain is to be laid around the foundation and connected with sewer.

There are to be two chimneys with wall 4 in. thick. The flues are to be $7\frac{1}{2} \times 7\frac{1}{2}$ in. in the clear for one outlet and $7\frac{1}{2} \times 11\frac{1}{2}$ in. for two outlets, all flues to be plastered on the inside and laid in cement mortar. The fireplace chimney is to be built outside the frame wall and is to be anchored to the frame work with iron anchors every three feet. The fireplace is to have a trimmer arch to support the

tion studding are to be 2 x 4 in. spaced 16 in. on centers and there is to be a single plate at the bottom and a double plate at the top composed of 2 x 4's. The stud walls and partitions are to have 2 in. bridging between the floor and ceiling. All corners are to have diagonal bracing on the stud walls and partitions. The walls are to be furred out where soil pipes occur. Double headers are to be used for windows and doors. All the framing is to be thoroughly trussed.

Shiplap 1 x 6 in. is to be nailed horizontally over the exterior walls, and on this is to be placed a two-ply building paper, which is to receive $\frac{3}{8} \times 6$ in. redwood or cedar shakes laid 12 in. to the weather. If shingles are used they should be exposed 6 in. to the weather.

Front Elevation of the Building—Scale $\frac{1}{4}$ In. to the Foot

Floor Plan—Scale $\frac{1}{16}$ In. to the Foot

A Five-Room Bungalow of Moderate Cost

hearth, the arch to be of brick or concrete at least 20 in. wide and the full length of the chimney breast. The fireplace is to be lined with fire brick and the face to be built up with pressed brick laid in colored mortar. The exterior brickwork of the chimneys is to be of ruffled brick.

The framing lumber is to be Oregon pine or its equal, depending somewhat upon the part of the country in which the home is built. The mud sills are to be 2 x 6 in. and the floor beams 4 x 6 in. The first floor joists are to be 2 x 8 in. and the ceiling joists 2 x 4 in., both spaced 16 in. on centers. The exterior studs are to be 2 x 4 in., also spaced 16 in. on centers.

A double floor joist is to run lengthwise under partitions. All spaces between joist and partition shall be blocked the full depth of the joist with solid block 2 in. thick. Where the floor joist is not in one piece it is to be spiked over bearings. Parti-

The rafters are to be 2 x 4 in. and the collar ties 1 x 6 in., all laid 32 in. on centers. Over the 1 x 6 in. sheathing is to be placed a two-ply building paper and this in turn to be covered with shingles exposed $4\frac{1}{2}$ in. to the weather. The top and sides of all openings are to be flashed.

The porch brickwork is to be of red ruffled brick laid up in black cement mortar, pointed. The porch and buttress caps are to be of smooth cement 4 in. thick and colored to match the porch floor. The floor is to be of concrete.

The subfloors are to be of 1 x 6 in. pine, laid diagonally, and covered with a two-ply building paper. Living and dining room surface floors are to be $\frac{7}{8}$ in. quarter sawed oak flooring, blind nailed every 8 in. All other floors are to be of pine.

The exterior trim is to be of clear pine and all interior finish is to be of slash grain pine. The dining room is to have a plate rail and a wainscot

An Attractive Five Room Bungalow of Frame Construction well adapted for the Suburbs, the Lakeside or the Seashore. Plans may be obtained in accordance with the description presented in this issue.

Section Through Main Wall—Scale $\frac{1}{4}$ In. to the Foot

Elevation and Section of the Fireplace in the Kitchen—Scale $\frac{1}{4}$ In. to the Foot

Medicine Cabinet Over Wash Bowl in the Bathroom—Scale $\frac{1}{4}$ In. to the Foot

Miscellaneous Constructive Details of Five-Room Bungalow of Moderate Cost

which shall be 4 ft. 6 in. high with 1 x 12 in. boards and $\frac{3}{8}$ x 2 $\frac{1}{2}$ in. bottoms. A chair rail is to be run at the top of the hardwall plaster in kitchen and bathroom.

There is to be a built-in desk and a bookcase in the opening between the dining and living rooms as shown in the details. All built-in work is to have mitered and glued corners and to have a casing run around them.

The Plastering

All plastering is to be sand finished excepting in the bathroom, which is to be wainscotted 6 ft. 8 in. high with smooth, hard wall plaster troweled down to a smooth finish. All sand finish plaster surfaces are to be sized and tinted.

The woodwork in the living and the dining rooms is to receive one coat of stain, one coat of filler and two coats of flat varnish. All other woodwork to have three coats of flat white and one coat of best white enamel.

The front door is to be glazed with beveled plate glass and all other doors are to be of five panel Colonial type. The buffet is to have glazed beveled plate glass doors and plate glass mirror.

The kitchen sink is to have lap front drawers, doors, bins, shelves and breadboard. The sink top and back are to be constructed with rough lumber covered with chicken wire which is to be covered with composition. The "cooler" closet is to have removable wire screen shelves and a wire screen vent at top and bottom to run to outside of building.

The Bathroom

The bathroom is to contain a medicine cabinet, with $\frac{1}{2}$ in. shelves and 1 $\frac{1}{8}$ in. door glazed with beveled plate mirror. The closet is to have a vitreous china tank, wash down bowl, white enamel seat and cover. Tubing, fixtures, etc., are to be nickel plated. There will be a 5 ft. porcelain enameled bath tub with a 3 in. roll rim.

The house is to be piped for gas and wired for electric lighting and call bells.

All surface woodwork is to be painted with three coats of white lead and linseed oil. The roof shingles are to be stained green. Exterior siding is to receive two coats of silver mixed paint. Ceiling of porch and under side of eaves are to be given three coats of white lead and oil. The screen porch floor and back steps are to receive three coats of best floor paint.

Arrangement of Rooms

An examination of the floor plans shows that the front door opens into the living room, which is connected with the dining room by means of a wide opening. To the left of the entrance is a bedroom which connects directly with the bathroom, as does also the other bedroom which opens off the dining room. A rear porch provides entrance to the kitchen and to the cellar.

Blueprints of this design covering plans, elevations and various constructive details all drawn to convenient scale for the builder, together with type-written specifications, can be obtained for \$10. In ordering, a request should be made by the prospective builder for design No. 680.

The Metamorphosis of the Attic

The attic of delightful childhood memory still may be found in old-fashioned homes where father uses a "mustache cup" and a plush-covered photograph album with a heart-shaped mirror and brassy clasps occupies a prominent place on the "center" table, says a writer in the *Hoggson Magazine*. But for the most part, the attic, as we recall it, is a thing of the past, a thing of hallowed memory and romance.

Of course, there has been a more or less appreciable movement by certain modern-day pseudo-poets to popularize attics by inhabiting them, and calling them Somebody-or-Other's "Garret," but this is purely an effort to create an interest in bad verse. No, attics will never be in again.

But we digress. The old-fashioned attic! Well might it have been called the heaven to which all good and much-loved things went when they "died." And this happy hunting ground of the wornout provided the early idea of Paradise to the children of the house. It was a veritable treasure trove and its wonders were never exhausted. The lost, the strayed, the forgotten, the cast-off, all found their way there. Truly, to dust they returned.

Broken dishes piled up on the table that had suffered the loss of a leg and leaned its sagging weight on a box of sea shells and corals, the gift of a sea-faring uncle; Jimmy's hobby horse, which had fallen in the battle of boyhood against babyhood, stood forlorn and alone. Sabres took on a coating of rust, as did the brace of heavy army pistols hanging from rusty nails. Trunks and toys, furniture and old clothes, books and . . . ! But why enumerate? This is not an inventory.

A visit to the attic was an adventure calculated to entrance with delight, and thrill with fear, the daring explorer. From the vantage point of the top step the musty smell and the stillness of the atmosphere portended deep and unfathomable mystery—anything seemed possible in such a place.

In the dim light, rows of headless figures hung along the wall; it was Bluebeard's forbidden room. In a dark corner, a wicked animal crouched; two bright spots gleamed out viciously, and when a surprised and frightened mouse scurried across the floor, well, who wouldn't close the door and run!

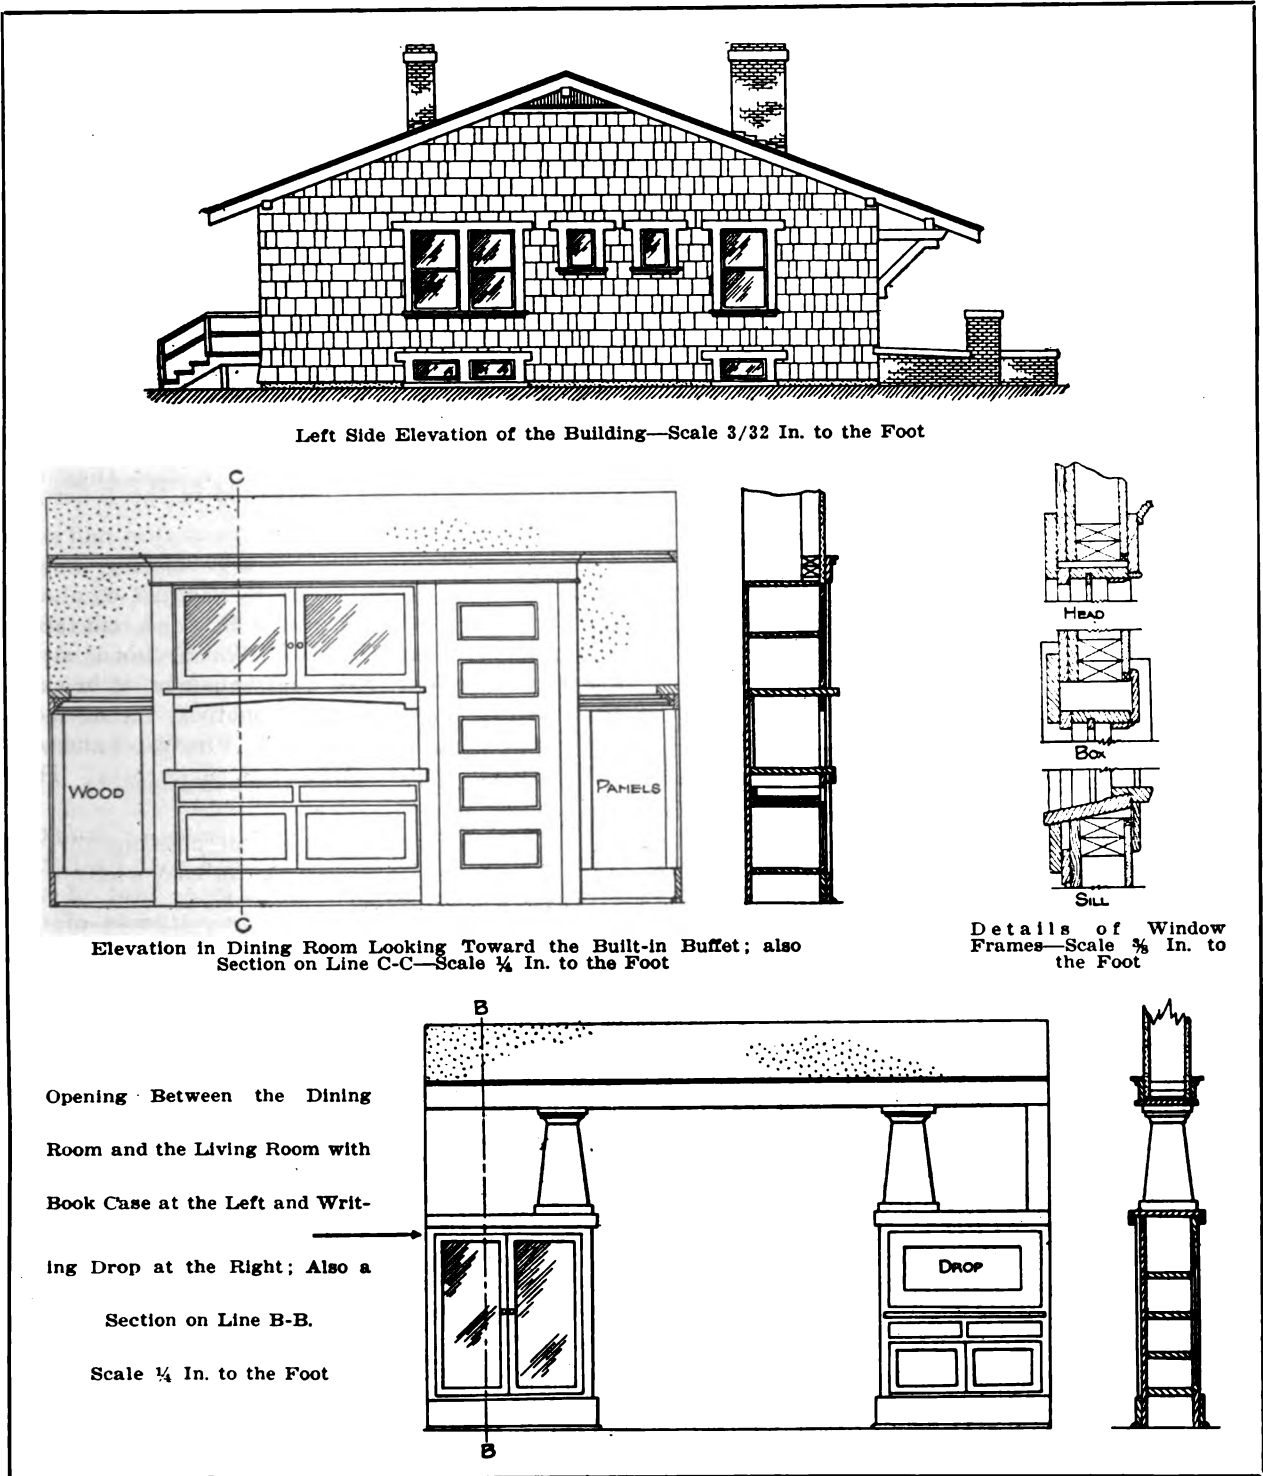

But there was no resisting the subtle lure of the unknown. Summoning new courage and a playmate as reinforcements, another attack was made and boldly pushed to a successful completion. But how disappointing for the moment, when more intimate investigation disclosed the headless figures as old military uniforms and army caps! And the eyes of the wild beast proved to be only a glint of sun on the shining knobs of a pair of old brass andirons!

The attic then accommodatingly became a safe retreat, and afforded in its many volumes of yellow-leaved books the desired thrills for excitement in the stories of other's adventures.

Splendid though were the attic's possibilities as a theatre. Cords stretched from rafter to rafter, a couple of old sheets, and there was a curtain. Now the old hair-covered, nail-studded trunks were truly treasure chests filled with the most gorgeous costumes any cast need wish. The only requirement was that a skirt be long enough to sweep out behind

and drag heavily on the floor as the heroine moved. A large feather, drooping sadly from the large hat brim, gave to Hamlet the necessary melancholy air. A train for the heroine and a feather for the hero! It was enough. Of what use is imagination?
And as for playing house!
Shall we shed a tear of regret at the passing of the old-fashioned garret, fragrant with its dried

a thorough understanding of what a child loves. It is a retreat that is their very own, just as they would have dreamed it. If you told them that the alcoves were formed by chance in the plan of the big house, they would smile incredulously. There is an alcove for each child, where each has her own individual set of furniture, decorated with her own story-book pictures. All of them delight in the

A Five-Room Bungalow of Moderate Cost—Elevation and Miscellaneous Constructive Details

herbs and steeped in an atmosphere of romance? No, for nothing has been lost to the children who have, by prior right, title, inheritance, and custom, the first call and privilege to that portion of the house.
The attic now provides the home with the most delightful of play rooms, that show in every detail

quaint Kate Greenway figures on the walls and hangings, and the blackboard against the chimney piece.
Deep shelves furnish cages in which the wild animals sleep at night; and the tired hobby horse finds a stable and rest. Baby has a playground all her own, out of danger from prancing steed and

ranging elephant. There is a quiet corner for nurse, too, fitted out with a low chair and table where she sits with her mending basket. The possibilities of the attic for a playroom are unlimited and just now coming to be realized. It is a place of enchantment.

What wonderful things are to be seen from the high-up windows where the sunbeams peep in to wake the toys! Perhaps the view may show ships far out on the river or bay, or miles and miles of tree tops tossed in the wind, and soft, white, piled-up clouds. When out walking with nurse in the park or grounds, there isn't so much to see; just a little bit close by, and here is a look over the whole, wide world, which is so full of things to make stories about.

Repairing Plastered Walls in Australia

An account of how plastered walls are repaired in Australia may not be without interest to American builders and we therefore present the following from the *Australasian Decorator and Painter*:

"To repair a plastered wall prior to repainting offers a few minor features to which reference here may not be out of place. A good job is impossible if cracks show, as they have a habit of doing unless properly treated. Where defects are many it is better to secure the services of a plasterer than to trust them to workmen who may not only fail to do the work properly but may take a great deal of time over the job.

"In the case of bulges or loose plaster it is necessary to pick out the defective parts completely down to the bare laths, and also extending the cutting process half-an-inch or so on to the surrounding plaster. There should be no sharp points or loose plaster near the edges of the patch. It is well to shape the cut-out portion round, and level the edges inward so as to give the new plaster a grip. In stopping the hole the main consideration is to forestall the possibility of the patch shrinking and assuming a lower level than the surrounding surface.

"To avoid this it is necessary to do the work in at least two operations. First, mix the plaster with a proportion of coarse sand. Wet the laths and the edges of the old plaster thoroughly, apply the first coat of plaster, and level with a straight edge. Allow to dry hard before finishing with plaster containing no sand. The plaster used may be either plaster of Paris and whiting (half and half), Keene's cement or one of the new plaster preparations. If the patch is large, one requires to follow the practice adopted by plasterers and use the straight edge and wood float, finishing by trowelling the surface of the plaster with the edge of a plasterer's steel trowel until the surface is dry and hard, applying water freely to the surface during the process.

"In stopping cracks the same process may be adopted, or modified if the cracks are small. Cracks if other than miniature require to be cut out, that is to say, deepened and straightened so as to neutralize the possibility of one edge being lower than another, and to provide a good grip for the stopping. Cracks stopped without being cut out usually show a bevelled edge which is almost as bad as are unstopped cracks. By widening a crack it is less apt to show when properly stopped. In stop-

ping it is well to substitute for stopping knife blades of wood shaped like a chisel knife. Steel knives leave marks which usually show up clearly under coats of distemper or paint."

Convention of Sheet Metal Contractors

What is regarded as one of the most successful conventions ever held by the National Association of Sheet Metal Contractors took place in Peoria, Ill., on June 20 to 23. Many interesting papers and addresses were presented which contained constructive suggestions and provoked much valuable discussion that enable the delegates to return to their local associations with enthusiasm and determination to carry out the recommendations which were made. Particular attention was given to the apprenticeship question, and an unusually interesting feature was an exhibit of work done by boys in different sections of the country.

Trade development was also considered and Secretary Allen W. Williams of the National Warm Air Heating & Ventilating Association told of the progress made by the furnace makers in educating the public to the value of properly installing furnace equipment.

The election of officers resulted in the following choice for the ensuing year:

President.....George Harms, Peoria
1st Vice-President....Frank B. Higgins, St. Louis
2nd Vice-President....Herman H. Lind, Cleveland
3rd Vice-President.....T. T. Walsh, San Antonio
4th Vice-President.Otto Guessenhainer, Milwaukee
Secretary.....Edwin L. Seabrook, Philadelphia
Treasurer.....W. A. Fingles, Baltimore

There were also elected three trustees to serve for a period of three years.

In the contest for the place of meeting for the 1917 convention Cleveland was an easy victor over Chicago and Peoria.

New York Office of Portland Cement Association

By amendment to the constitution of the organization so long known as the Association of American Portland Cement Manufacturers, the name has been changed to Portland Cement Association with head offices in the Conway Building, 111 West Washington Street, Chicago, Ill.

The Association has recently opened a New York office in the Architects' Building, 101 Park Avenue, which is in charge of Louis R. Ferguson. With the addition of this office the Association now has five branch offices, the others being in Atlanta, Kansas City, Dallas and San Francisco.

The large hotel built on the grounds of the Panama-Pacific National Exposition at San Francisco, Cal., and which was constructed principally of white pine and steel, was sold for 16,000, the original cost having been about \$225,000.

"If rooms be square, their height should not exceed five-sixths of the sides, nor be less than four-fifths, but in oblong chambers it may be equal to their breadth," is the opinion of a writer of colonial days prominent in architectural matters.

Some Aspects of Modern Shingling*

Treatment of Gable Ends—The Standing Gutter and Shingled Cornice—Finish at the Ridge

BY EDWARD H. CRUSSELL

ON the ends of gable roofs the shingles are usually allowed to project over as they do at the eaves, or say about 1 in. Many workmen are able to keep a straight line up the gable by the eye alone, but as nothing looks much worse or is harder to correct than a mistake at this point it is better to use a guide.

The guide may be either a line stretched from top to bottom at the correct projection, as was done at the eaves, or it may be a strip of the correct thickness tacked temporarily to the end of the roof boards. Where a strip is used the amount of projection may be varied slightly in order that a piece of the ordinary $\frac{7}{8}$ material may be utilized. The strip need not be more than 3 or 4 ft. long, held in place with a couple of nails and moved up the gable as required.

The strip is, perhaps, better than the line for the novice, because there is a tendency to crowd the line out of place by keeping the shingles too close to it. On the other hand, the writer knows of an

gable the writer saw used some years ago, but does not recommend. In this instance the workman let the shingles project over any way at all, just as they happened to come; when the ridge was reached he snapped a line down the gable at the correct projection and cut off the shingles to it with a rip-saw. As stated however, I do not recommend it.

Fig. 27—Showing Sharp Corner on Hatchet

In finishing the courses at the gable it is, in most cases, better to lay the outside shingle first, so as to do any trimming that may be necessary on the shingle next to it.

Most workmen can understand why a double course of shingles is always needed at the eaves, although many of them overlook the fact

Fig. 19—Section of Lower Edge of Shingle Roof

Fig. 20—Section of a Standing Gutter

Some Aspects of Modern Shingling—Treatment of the Gable Ends and Standing Gutter

instance where a strip had been tacked on the full length of the gable to serve as a guide, and when the time came to remove it, it was discovered that in this case the novice had nailed all his shingles to the guide strip. Not here and there a shingle, but every one of them, and the edge of the roof after the strip was taken off had a rather interesting but undesirable fringe of nails.

One method of getting a straight line up the

that even with the first course doubled it is still the weakest or most vulnerable section of the roof—every other course but it, in a properly constructed roof, consisting of three thicknesses as is shown in Fig. 19, which represents a sectional view of the lower portion of a shingle roof drawn to scale.

When the roof has a standing gutter, as shown in Fig. 20, a doubled course is also needed above it, for the same reason that one is needed at the eaves. The writer has known of this fact being overlooked by an experienced mechanic simply be-

*Copyrighted, 1916, by Edward H. Crussell.

cause this style of gutter was new to him, although he had done plenty of shingling.

So much is being said in this series about mistakes that the reader might possibly be led to suppose the writer had spent his life among a class of

Some Aspects of Modern Shingling—Fig. 21—Shingle Roof with Every Fifth Course Doubled

workmen who never did anything but make them. Such is not the case, the facts being that a carpenter may work for years in the larger cities, and be a good and thoroughly experienced mechanic without ever having been called upon to lay shingles. This is often overlooked by the foreman or person in charge, who consequently does not always give the shingling the amount of supervision it deserves.

Mistakes in shingling are hard to rectify. Imagine the roof shingled to the ridge, or even half-way up, before it is discovered there is only a single row of shingles above the gutter. How would you go to work to correct such a mistake? It isn't likely that this could happen more than once to the same executive, and the only reason for speaking of it here is so that those who have not yet had such an experience might be able to profit by the experience of those who have.

Besides those places already mentioned as requiring double courses, it has, of late years, become the practice to insert them at regular distances all the way up the roof, making, say, every fifth or sixth course a double one. This practice is shown very clearly in the picture, Fig. 21. It has the effect of breaking up the monotonous appearance of a large roof, giving it a certain style and character of its own, but care is needed in the arrangement. The roof space should be equally divided and the double rows not too far apart, or instead of improving the appearance they are likely to suggest that the shingler forgot to remove his toe-laths.

Another style of modern shingle roof decoration is that of curved eaves and edges as pictured in Fig. 22. There seems to be different ideas regarding what this style of shingling is meant to represent. Combined with a Colonial style of architecture and properly arranged and colored, it gives something of the effect of Spanish tile. With another style of architecture and arrangement it gives what is known as a thatched roof effect. In striving after this thatched roof effect some rather

unique shingle arrangements have been attempted, one of which is shown in Fig. 23.

It is hardly necessary to say that the gage and hatchet method is of little use on work of this kind, and although to the uninitiated it may seem easy, anyone who has attempted it knows different. It is the sort of work that calls for the patience of Job, combined with an artistic temperament. Perhaps the best method of lining the courses is to make three or four short patterns of different degrees of crookedness and interchange them in whatever order seems best. The patterns should be of such a length that they can be held with one hand while the other hand runs a pencil the full length of them. The shingles in the picture were cut and arranged according to a detailed drawing, one man on the ground cutting and numbering the different courses, another on the roof laying them. Fig. 24 is a picture of another portion of the same roof.

Shingles laid on round corners must be well nailed—the butts as well as the tops. They will also, in most cases, require soaking in hot water until sufficiently pliable to bend to the curve without splitting. Steaming would be better, of course, but is in most cases out of the question because of lack of facilities. For the hot water, an easy method is to set up a galvanized iron wash tub on a few bricks, fill it with water and keep it hot with the cuttings that are always to be found where wood-work is being done.

Fig. 25 is a picture of a church on which, as can be easily seen, a considerable quantity of this round shingling had to be done. The shingled cornice on this building is another feature worthy of note; it is, perhaps, shown more clearly in Fig. 26, which is a rear view of the same edifice. This view also shows the top of the spire omitted from Fig. 25.

Fig. 22—Shingle Roof with Rounded Edges

The spacing of the last few courses of shingles on a roof usually needs to be varied slightly in order that there may not be an extra wide or narrow course at the finish. Where ridge boards are used the width of them should be taken into consideration and the courses arranged so that the last one shows

the correct width of exposure from the lower edge of the ridge board.

In addition to varying the courses at the ridge it is well to check up every once in a while as the

Fig. 23—Rear View of House Shown in Fig. 24

ment always being taken from the same point.

Many roofs are finished with a row of shingles laid lengthwise instead of ridge boards. This method was used on the building pictured in Fig. 21, though it may not be readily discernible in the reproduction. The ridge shingles are usually of the same width as the courses and are laid from each end of the roof so as to finish in the center.

There is a little kink to be mentioned in connection with cutting off the ends of the last courses of shingles that project over at the ridge. The

Fig. 24—Roof So Laid as to Give the Thatched Effect

Fig. 25—Church Tower with Shingled Corners

Fig. 26—Rear View of Fig. 25, Showing Shingled Cornice

Some Aspects of Modern Shingling

work progresses and see if the courses are running parallel with the ridge. Where several men are working on a long roof it is easy to get quite a variation unless this matter is attended to. On old roofs it is no unusual thing to find the variation in the roof itself.

The easiest method of checking up is with a rod, one long enough to reach the entire distance. Or, if the distance is too great for a rod, use a steel tape. Measuring with rule and pencil is to be avoided as being worse than useless. Large nails or spikes may be driven into the ridge of the roof to butt the rod against and assure the measure-

carpenter usually takes a saw for this purpose, but the best and quickest method is to have a sharp corner ground on the rear edge of the hatchet, as shown in Fig. 27, and cut the shingles by drawing this corner over them, while exerting pressure on the head of the hatchet with the other hand. Only those who have tried it or seen it used will believe how quickly shingles can be cut by this method. It isn't always necessary to cut the shingles right through; if they are scored deeply enough a tap with the hatchet or the edge of the hand will break them off.

Trade Topics—Every Reader is Invited to Participate

Marking Centers for Lattice Screen for Porch

From W. M. L., Orange, N. J.—Will some of the practical readers of the paper kindly tell me how to mark centers for diagonal latticing of a porch screen?

Answer.—The following comments in regard to the above query are furnished by W. S. Wilkin: From the question of the correspondent I take it he intends to nail the lattice together without any frame and place it on a porch between the

take the long side of the screen on the blade of the steel square and the short side on the tongue. The blade will give the long bevel and the tongue the short bevel. Set the T-bevel to this and mark both ends of the strip as shown at A and B. This will give the exact length and bevel of the long piece.

There will be two pieces just like this, for the lattice can be turned over. If both sides were not alike he would have to make them in pairs and keep the face side one way. There will be four of each of the other kinds.

Now from the center to the end A mark a long bevel at each of the points as shown, and from the center to the end B mark a short bevel as shown. This will give the length and bevels of each of the other pieces.

Now instead of marking the centers to nail by I would mark just one half the width of the lattice out of cen-

Marking Centers for Lattice Screen for Porch—Sketch submitted by Mr. Wilkin.

rail and lintel to support running vines. If this is the case each piece must be marked or laid off in some way. If he has a large floor space he can make a drawing of the panel as shown in the accompanying sketch, and nail up over this. Then take a straight-edge and mark the sides to saw off after it is nailed together.

I think the way I have shown is the best way to go at it. First find the width and height of the screen; then decide how many pieces to run through. I have used nine. Now find the diagonal length of the screen, which may be done by mathematics or by the use of the steel square. Next take a strip of the lattice and lay off this length as shown from A to b. If he is going to use nine lattice pieces divide this length into ten equal spaces, square across at these points and run a line down the center of the strip.

Find the bevels on the ends of the lattice; then

ter, then he can always bring the edge of the lattice to this line when he is nailing and can see what he is doing.

It will be seen at A on the A end of the rod that the long bevel will give the point to mark off the side of the lattice. He can stand several pieces of lattice on edge, and clamp them together and use the steel square to mark them on the edges. The short bevel will also give the side of the lattice, but not the same side on the same edge of the rod. Naturally we want all marks on the same edge of the strip so as to save turning it over when laying off, and we want all marks on the same side of the lattice when we begin nailing it up or we may get things mixed and get some on the wrong side of the line.

In order to do this right, find the bevel between two pieces of lattice—in this case it is the same as the short bevel, but it will not always be the

same. To do this, take the long side of the screen on the blade of the steel square, and the short side on the tongue; then mark on the long side. Reverse the square and mark on the long side again; that is on the blade. The intersection of the two lines will be the angle the lattice pieces will cross each other.

Lay off this bevel on the B-end of the rod, as shown at B. If the correspondent wishes to mark the center of the lattice, instead of the sides, he can do it, for he will see that each point on the rod marks the center of the lattice.

Designs of Cobblestone Bungalows

From Louis Miller, Arcadia, Mo.—Thinking that some of the readers might possibly be interested in the several bungalows which I planned and built not long ago, I am sending a few pictures of them, together with the floor plan of one of them. The buildings are constructed of what is known as a mountain nigger-head porphrey cobblestone of an iron color, with brick corners and concrete belt course at the floor line. The front

A Street View Showing the Pergola at the Corner

A Detail of the Cobblestone Porches

furniture is all white enameled and the walls are tastefully decorated in water colors.

It may be interesting to state that Acme plastering was applied direct to the walls inside without any furring strips whatever, and water and dampness have never as yet been known to go through the walls.

The buildings are fully equipped with running water and provided with electric lights and are rented to summer visitors.

I would say that Arcadia is situated in the Ozark Mountains, ninety miles south of St. Louis, and nature intended it for a summer resort for tired people. The scenery is fine and the best of water gushes from the foot of the mountain.

Some Comments on Shingling

From John Upton, La Fargeville, N. Y.—I have been much interested in the series of articles on modern shingling now appearing in current issues

A Side View of the Bungalow of Which the Floor Plan is Here Shown

Floor Plan of the Bungalow Shown Above

Designs of Cobblestone Bungalows as Constructed by Louis Miller

and back porches have concrete floors, while the balusters are constructed of a buff colored cobblestone and capped with a concrete coping. The different colored rocks form a pleasing contrast and give rather striking effects.

The roof is covered with shingles creosoted red in color. The chimney is of cobblestone construction lined with brick. The windows are of the casement type with concrete sills.

The inside finish is of pine, white enameled. The doors are of the regular bungalow type. The

of the paper, and I am prompted to offer a few comments on the subject. In this section of the country we use 2 x 4's for roof staging. Now instead of following the method described in the April issue and sawing off the shingles after the roof is finished, we nail a few shingles to the 2 x 4's in such a way that they will come on the under side, butts up, and then nail these to the roof on top of the regular shingles. This method will leave a few small holes in the top shingles but this may be easily remedied by driving up

a bit the shingle that is immediately under it.

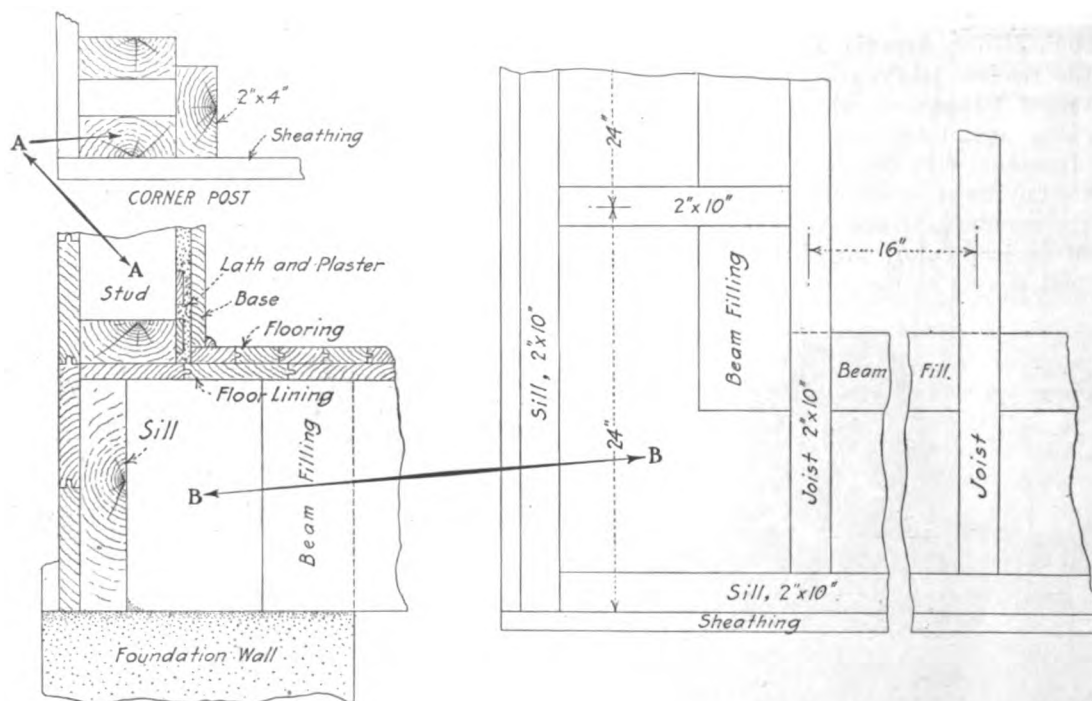

On steep roofs we sometimes set the 2 x 4's on edge and put on other shingles from the top edge down to the roof for braces. I have used this method on roofs with a rise of 20 in. to the foot.

Some men will use a 2 x 4, a 2 x 6, or even a 1 x 8 set on edge on roofs that are only of moderate pitch, but I prefer a 2 x 4 put on flat as I have described. Some use the iron brackets and like them.

In shingling we do not use a hatchet with a gage but a hammer, and strike one or two lines with a chalk line as a guide, or else we use a straight edge. By using a short piece of board

stains are caused in many cases by allowing old chimney or sooty bricks to be laid in the walls. They will show a yellow stain through the plastering and also the paper. It may be that an old paving brick will sometimes find its way into the wall where old bricks are used and it will show for a long time a damp spot on rainy or sultry days. If the bricks are covered with a good coat of gas tar before plastering they will never stain either paper or white coat.

If the walls are damp from other causes, remove the plastering, brush off the wall with an old broom, give it two good coats of the tar and then replaster over the tar. The dampness will

Construction of sill and corner post as described by Architect W. H. Blair of Janesville, Wis.

5 in. wide laying loose on the straight edge we can run two courses at a time.

Construction of Sill and Corner Post

From W. H. Blair, Jamesville, Wis.—I am sending herewith a tracing of the form of sill and corner studs which I have used for some years and found to be the most satisfactory of any method which has come to my knowledge. When well pointed on the inside of the sill piece and beam filled it makes a perfect seal forming a dead air space. When the studs are well spiked in the form shown, they make a solid corner preventing the plaster giving way.

Preventing Old Brick Work from Discoloring Wall Paper

From M. C. D., Baltimore, Md.—In reference to the inquiry of "W. W.," Baltimore, Md., regarding some method of treating old brick work so as to prevent the discoloration marks coming through the wallpaper, and which appeared in the May issue, I take pleasure in describing a remedy which I am sure will produce satisfactory results. The

not show through the plaster. The latter will adhere to the tar the same as to the bricks.

From Builder, N. Y.—In regard to the query of "W. W.," Baltimore, Md., I desire to say that his question is confusing. I cannot make out whether he wants to use more brick, or take the plaster off that which he has used. If he wants to treat the mortar that is on the brick it is another question. I cured one such case with Alabastine. In his case he should try coating the stained plaster with two coats of yellow shellac, and then give it two coats of Alabastine. If he has taken off the plaster he should shellac the brick.

Details of a Sewing Cabinet

From H. W. N., Superior, Wis.—I am sending drawings for a sewing cabinet which is somewhat different from any usually seen and it takes well here because it is out of the ordinary style. The carpenter often has leisure hours which he can devote to turning out useful articles for the house as well as adding a little to his income. I have made two cabinets such as are here shown and they were well regarded.

Referring to the sketches, Fig. 1 represents the appearance of the finished cabinet with details of

the framing. Fig. 2 is an elevation of the top rail and Fig. 3 of the bottom rail, each being 12½ in. in the clear. The one at the back has a half-inch tenon. Fig. 4 is a view of the drawer end and measures 2½ in. Fig. 5 is a detail of the carved molding which is broken around the veneered top. It is dressed to shape and cut out with a ⅜-in. chisel, making a ⅛ in. V cut. Fig. 6 is a cross-section showing reiforcement of the frame with corner brackets. In Fig. 7 is shown a detail of the drawer, the sides of which are 2½ in. deep and ⅜ in. thick. The corner compartments are 3 x 8 in., the center one at the front 3½ in. by 4½ in. and the

dows nearer to the doors and place the upper windows over them; then those over the doors could be made smaller or left out altogether. This arrangement might bring the spaces so as to avoid some of the different sizes of blocks which he mentions.

Another change would be to make a belt course 6 in. high over the lower windows. This would bring the blocks up in line with the upper windows the same as the lower ones.

There could be a belt course over the upper windows or the cornice might be started 6 in. lower. The cornice could have almost any de-

Details of a Sewing Cabinet—Contributed by "H. W. N."

one immediately in the rear of it, 3 x 4½ in. In Fig. 8 is shown the drawer pull, ⅞ x 1 x 2 in. carved out of the same material of which the cabinet is made.

Comments on Ten-Room Twin House

From John Upton, La Fargeville, N. Y.—In answer to the correspondent asking for comments on his ten-room twin house, I beg to say that even though the two windows over the doors are not needed it seems well to put them in so as to render the design more symmetrical and avoid weight over the door. He might bring the lower win-

sired overhang if rightly constructed. The idea is to corbel it out gradually using moldings for the corbels and plain boards for the vertical parts—ornamented if desired. The ends should be left plain—not returned. Wire should be used here for reinforcement and in the caps over the openings, also in the water table and belt course.

A 100-Ton Silo for \$200

From Charles Alma Byers, Los Angeles, Cal.—Some of the readers in the farming sections may be interested in the silo shown herewith and I will, therefore, give a brief description of it. It

has a capacity of about 108 tons, cost a little less than \$200, is constructed entirely of wood, except the base, which is of concrete, and was completed within about two weeks from the time it was started. As will be realized from the picture, it is of extremely simple design, and yet it has proved, by one season's use, to be very serviceable and in every other way entirely satisfactory.

The inside measurements of the silo are 14½ ft. in diameter by 32 ft. in height. The concrete base, resting on a foundation of broken stone, is approximately 16 in. thick, and is a circular slab 15½ ft. in diameter. The roof is an octagon, and is shingled over 2 by 3 in. rafters and 1 in. sheathing. The uprights, 40 in number, are also of 2 by 3 in. material, consisting of Oregon fir, and the siding is of ½ by 8 in. California redwood. This siding consists of two thicknesses of the same material, with a sheathing of tarred roofing paper

General View of a 100-ton Silo

intervening, and is laid so as to lap all joints and edges on centers, making the silo watertight. The uprights are dovetailed into the circular-cut mud sill, and the latter is securely fastened to the concrete base with anchor bolts. The chute and ladder are naturally constructed of wood also, consisting of 2 by 3 in. framing and 1 in. boards and strips.

Half-inch redwood is easily sprung to create a cylinder, like this silo, and at the same time is very little inclined to check or crack. For an inexpensive and quickly constructed silo, the one here described constitutes a very practical model.

Mixing Paints and Care of Brushes

From D. P. D., Redford, N. Y.—In answer to "R. L., Wilson, Minn., I may say that too much oil and turpentine injure paint. If the paint runs on a vertical wall, making hairlike cracks, it is too thin. If the lead is good, the surface in good

condition and the color gray, then not enough coats are used. When non-drying pigments are used in priming, or non-drying oils are used, then injury follows. Another cause of injury is found in greasy or wet surfaces. Two coats are not enough on new surfaces.

Kerosene is a good cleanser of brushes. Place it in a can and churn the brush forcibly. Beating it against a solid surface will thoroughly clean it. Brushes should be cleaned before laying away.

It is bad practice to paint in a temperature below 40 deg. Fahr., because the walls are apt to be damp and too much turpentine must be used.

From John Upton, La Fargeville, N. Y.—In answer to the query of "R. L., Wilson, Minn., in regard to the mixing of paints and the care of brushes, I beg to offer the following comments. Making white lead look white does not depend on the manner of mixing, although one should add the oil a little at a time and work the paste over thoroughly. A small quantity of zinc white will make paint whiter.

Brushes can be cleaned by washing in kerosene or turpentine, rubbing on a rough board and wiping with a cloth. They can be kept in oil, kerosene or water, but should be suspended in the liquid and not allowed to rest on the bristles.

Answering the last paragraph of his communication I would say that it is not generally considered good practice to paint when the temperature is near zero, but there may be instances, as in priming new work, where it should be done rather than let it go without. In such cases choose a day when the sun shines and there is some prospect of fair weather.

Keeping a Garage Floor Clean

From S. W. C., Elizabethville, Pa.—Can some of the practical readers of the paper tell us how to cover, treat or replace a board floor of a garage repair room which is located on the second floor? The floor joists have, what seems to us, too long a span, 20 ft., to permit the use of a cement covering. We cannot keep the board floor clean and it makes our insurance high.

Perhaps some of the readers will be able to tell us of a grease-proof, fireproof material we could put on the floor.

To Drive a Nail in Plaster

If you wish to drive a nail in a plastered wall first put it in very hot water until it is thoroughly heated, says the *Woman's Home Companion*. You can then drive it in clean without breaking or chipping any of the surrounding plaster.

"Cold nails will make the plaster fall—
Don't try to drive 'em in.
Just boil your nails—approach the wall,
And hammer 'em like sin!
The plaster will not budge a mite
Though swatted like the dickens—
Hot nails are certainly all right,
Like incubator chickens."

Reinforced concrete construction in the Uuerto Plata district is becoming very popular, being used for almost all new buildings of any size.

Low Cost Cottage of Stucco Finish

Studs Covered with Sheathing Boards and
Stucco Applied to Metal Lath—Cost \$1200

THE attractive cottage presented herewith represents what may be accomplished by an amateur builder provided he has well defined ideas of the kind of a house that will meet his needs, and the enterprise to carry the work to completion. The owner of this cottage is employed during the day-time in a machine shop, and in carrying out the work of construction there were neither plans nor specifications, as the trade understands them, but all material was bought as required and labor hired by the day. The house contains six

The outside studs are covered with 3-in. tongued and grooved yellow pine boards put on over heavy tar paper and then the stucco was applied, about one year after the house was built. The roof is covered with shingles.

The floors are single throughout, and are of 3-in. tongued and grooved yellow pine. The walls are covered with patent plaster on wood lath.

The interior finish is yellow pine finished in natural grain. The dining room and parlor, or sitting room as some may choose to call it, are stained

The Stucco Coated Cottage of R. G. Herrmann at Wapakoneta, Ohio

rooms and bath, with one of the sleeping rooms located on the main floor.

The foundation walls are of concrete, 12 in. thick, the "forms" having been made of 2 x 4's and sheathing boards, all of which were afterward used in the house. The cellar has a concrete floor and drains to the sewer. At a point 20 in. above the floor the foundation walls recede for a distance of 28 in., thus forming a shelf all around the cellar for the reception of preserves, canned fruit, etc.

The first floor joists are 2 x 10 in. and the second floor joists 2 x 8 in., placed 18 in. on centers. The rafters and studs are 2 x 4 in.

a golden oak in order to match the furniture.

The stairway is open to the second landing, from which point to the top of the flight the walls each side are plastered.

The way in which the work was done by the owner—R. G. Herrmann of Wapakoneta, Ohio—and his two assistants, is interestingly described by him in a letter from which we quote the following:

"Although I have had previous experience in cement work this is the first job of stucco I ever tackled. The men who assisted me were inexperienced also, but had done a little plastering. We found that by using a wooden hock and wooden

trowel it left a surface rough enough for the next coat without any further roughing. We spread an old piece of linoleum on the ground to catch the material that fell, and thus effected a considerable saving. The hock used was about 12 x 12 x $\frac{7}{8}$ in. with a handle nailed to it, and this was used in applying the material to the lath, except in the case of the edges near the trim and windows and doors where the wooden trowel was used. The latter was made of 4 x 8 x $\frac{1}{2}$ in. board.

"The insides of the porch posts were finished smooth with a steel trowel; this being done so that I could screen the porch and fit to the posts. The posts and corners were squared by holding a strip of wood against the corners until the material was put on and then we allowed the strips to stick awhile until the cement had turned hard. We had no trouble with corners breaking.

"We put on the first coat one day, then sprinkled it that night and the next morning, and then we put on the second coat. The next day we put on the brush coat, this arrangement giving the cement plenty of time to take a good hold, and also give a good bonding quality. The work was thoroughly

dle of September, 1915. I kept the cement in the house in a dark corner and covered it with a dark cloth until I was able to use it. Some of it caked a little, but was readily pulverized by alternately picking up the bag and dropping it on the floor.

"The labor cost of putting on the lath and stucco—two men at \$2 per day each—was \$42.80. It took nearly 200 sq. yd. of lath—to cover the building, so that the total cost of labor was very reasonable, in fact only a trifle over 21c. per square yard for putting on the lath and three coats of stucco.

"The house has electric lights in all rooms, also gas and city water. It can be built for \$1,200; is sufficiently roomy for a small family, looks well and is easy to keep warm. My house is the first job of the kind in this town and has been attracting considerable attention."

Hardness of Various Hardwoods

A recent bulletin of the Northern Hemlock and Hardwood Manufacturers' Association contained a

First Floor

Second Floor

A Low Cost Cottage of Stucco Finish—Floor Plans—Scale 1/16 in. to the Foot

sprinkled night and morning every day for a week. It is as hard as a rock and no cracks have appeared.

"On May 5, 1913, I bought ten barrels of Medusa white waterproofed cement, but was unable to make use of it until the fall of 1915. The house shown in the picture was of frame construction with tongued and grooved weather boarding on it when it came into my possession. I gave it a good coat of paint, then covered it with cup expanded steel lath, to which I applied Medusa white waterproofed cement and Tuckahoe white crushed marble. The mixture was of the following proportions:

"The first coat consisted of one part Medusa white waterproofed cement and four parts Tuckahoe white marble; the second coat, one part white waterproofed cement and two parts Tuckahoe marble, while the third coat was of the same proportions as the second. The three coats made an average thickness of 1 in.

"The last of the stucco was put on about the mid-

table of the relative hardness of various hardwoods. Hardness is figured on the number of pounds required to imbed a steel ball .444 in. diameter, one-half its diameter into the side of the wood. The figures follow: Walnut—black, 900; maple—hard, 882; beech, 824; birch—yellow, 795; mahogany, 762; cherry, 664; maple—red, 613; sycamore, 609; maple—silver, 592; gum—red, 577; poplar—yellow, 388.

Oakland Building Law Revision

Following the recent agitation in Oakland, Cal., the city council has appointed an advisory committee of fourteen members of the Chamber of Commerce to revise the city building ordinance and outline a substitute designed to remove objectionable restrictions. The committee includes a number of well-known architects and engineers, as well as real estate and business men.

A Gas Dome for Indirect Lighting

Details of a Lighting Fixture for the Home
Which Will Be Found Both Timely and Practical

BY JOHN WAVREK, JR.

ONE of the many features of the modern home equipment which is subject to more or less frequent change is the manner of lighting the principal rooms. The beautiful, or at least what we have fondly believed to be beautiful, gas and electric domes of a few years ago are now supplanted to a large extent by the still more attractive indirect system of lighting. This indirect light is certainly restful to the eyes, eliminating as it does the glaring, direct rays of the brilliant gas or electric light; and the average mechanic may, with the aid of a little ingenuity, transform his ordinary means of illumination so that he may enjoy the luxury of owning an up-to-date indirect lamp.

In the description which follows I have endeavored to explain how this may be done with little

ornamental metal scrolls, as shown in the section.

Fig. 4 is an enlarged view of one of the brackets, of which there are four used in the present case. In most instances there are three supports, but owing to certain conditions the writer used four.

In case four supports are desired, procure from some gas-fixture concern a canopy similar to the one shown in Figs. 1 and 2. If, however, three supports are preferred, then a round canopy should be used. I would state, for the information of the uninitiated, that the canopy is the metal piece at the ceiling to which the hanging pieces are fastened. Next secure the metal pieces from which to make the supporting scrolls. These may be of iron or brass, but in my own case iron was used. These pieces are $\frac{1}{2}$ x $\frac{3}{4}$ in. and of sufficient length to

Fig. 1—Section on Line A-B of the Plan Fig. 3

Fig. 2—Elevation of the Fixture

A Gas Dome for Indirect Lighting Showing Some Details of Construction

expense to the wide-awake mechanic. Referring to the accompanying sketches, Fig. 1 represents a sectional elevation of the scheme. The original gas fixture is left as it was installed, and was only disturbed when the dome was put into place. This necessitated the removal of the fixture from the gas pipe and screwing it on again when the dome was in place. The original fixture serves to keep the dome in position by means of the cross-piece, as indicated in the sketch.

Fig. 2 is a general view of the light when completed but not put in place. Fig. 3 represents a plan of the wooden ring which holds the globe and which in turn is held in position by means of the

make the scrolls, which may be of more simple design than those shown if desired.

A glass bowl of any desired size can also be obtained in a gas-fixture establishment. The bowl shown in the sketch is 12 in. at the neck. Having determined the size of the bowl, we then lay out the wooden ring, which consists of three sections, as shown in Fig. 3, each section being made in four quarters. The joints of the section next to the upper one are made to go midway between the brackets, passing through the notch in the bracket. The other two members of the ring are fitted between the brackets, this method producing a very rigid piece of work.

Having now completed the wooden portion, it is necessary to bore three holes in the lower member of a size to allow a quarter-inch bolt to be placed therein. The hole should be made small enough to allow the threads of the bolt to be cut, which is accomplished with the bolt screwed in. These three bolts support the bowl, as shown.

Having constructed the different parts, the whole may then be assembled. The metal scrolls are fastened to the canopy by means of small bolts and are screwed onto the brackets of the wooden ring with good strong round-head wood screws.

At this stage the gas fixture is taken off, the dome pushed up into position and, if everything has been carefully measured, it is simply necessary to replace the gas fixture, which will serve to hold the whole thing in place by means of the cross-piece above referred to and as shown in Fig. 1. In order to make the job doubly secure there is a small set-screw placed in the neck of the canopy, and this also aids in holding the light in position.

The chains controlling the lighting of the gas mantle are passed over the rim of the wooden portion and allowed to hang down far enough to be

Fig. 3—Plan of Wooden Ring

Fig. 4—Detail of the Bracket

Gas Dome for Indirect Lighting

within easy reach of a person standing on the floor. After putting the bowl into place the indirect gas dome will be ready to do its work, and we have not the slightest hesitation in asserting that it will be found of great benefit by reason of the restful mellowness of the light.

Another New York Skyscraper

Another change has been made in the plans for the new building of the American Express Company, and the structure which it is now intended to erect will have a frontage on Broadway of about 80 ft., a depth of 210 ft., a frontage on Trinity place of 76 ft., and a height of 21 stories, instead of 32 as originally designed.

The lower part of the structure will be arranged in the same manner as a bank, the grade floor being equivalent to two stories with large bays, the central one of which will form the entrance to the building and be trimmed with marble and bronze. The first three stories will be of granite, the middle fifteen of glazed face brick trimmed with limestone sills, the upper three stories and balustrade will be of terra cotta with an archway serving to connect the two top floors.

The estimated cost of the structure is placed by the architects, Renwick, Aspinwall & Tucker, at \$2,500,000. The construction work is being done by Cauldwell-Wingate Company, New York City.

A Sound-Proof Building

What is said to be the first sound-proof building of its kind in this country if not in the world has lately been constructed at Evanston, a suburb of Chicago, Ill. Sound-proof floors, partitions and ceilings, forced warm-air ventilation, and hermetically sealed doors and windows, are features of the unique music practice building for the students of the School of Music of the Northwestern University.

The structure houses twenty-eight diminutive rooms, each measuring 6 x 9 ft., with ceilings 9 ft. high. The rooms are eminently usable for music practice; their practicability, however, is only by reason of the peculiar construction of the doors—a patented invention, says the *Scientific American*—which prevents the transmission of sound from room to room, supplemented, of course, by sound-proof partition walls.

Size of Rooms Required

In the existing music practice building of the school it had been found that a sufficient remoteness of one piano from another to furnish even a poor protection from the sound of a neighboring piano required rooms of at least 180 sq. ft. of floor space. Comparing the latter figure with the 54 sq. ft. of the rooms in the new building, the saving in building costs is at once apparent, while the sound-transmission is reduced to a minimum.

Four different methods of sound-proofing the partition walls have been adopted in different sections of the present music practice building, in order to learn their respective worth for future use in a larger music building which, it is hoped by the school authorities, may be built in the future.

No lath or plaster appears in the building except in that section of the structure where gypsum blocks have been used, in which case a thin coat of plaster was applied merely to give the blocks a smooth surface. Otherwise, 1-in. yellow pine sheathing has been used, covered with canvas; the latter in some instances is glued to the wall, and in others merely hung taut in the manner of tapestried walls.

The windows of the building are double; the inside window is hermetically sealed, while the outside one is hinged outwardly for convenience in cleaning. At a distance of 25 ft. from the building it is said that the twenty-eight pianos when in use can hardly be heard, thus amply protecting the neighboring property from sound-intrusion.

The Ventilation

Ventilation is effected by introducing air from out of doors at a point near the roof. It passes through a duct to the basement, through heating coils, through a spray, and thence by long individual pipes to the top of the wall in each room.

A vent in the baseboard leads the air by an individual pipe to the attic, where it escapes through a roof ventilator. The individual piping system prevents intercommunication of sounds between rooms.

The entrance halls and corridors are heated directly by steam radiators, but the practice rooms receive all their heat, air and moisture through the ventilating system.

The music practice building is of mottled red brick, shingled roof, and is two stories in height,

occupying a ground space of 28 x 59 ft. The interior woodwork is of birch in the natural color, the walls being covered with buff grey canvas.

The doors simulate the so-called sanitary flush doors, two of that kind $\frac{7}{8}$ in. thick being fastened together by means externally invisible with a $\frac{7}{8}$ -in. space between, the space in part occupied by sound-deadening felt and in part by the hermetical sealing mechanism. The doors are so constructed that a downward push of the handle closes forcibly the space between door and threshold, while the outer end of a finger, engaging with a cam, pushes the the door unfaillingly and forcibly against felt-mounted stop mouldings at the top and free edge of the door; in a word, the door when closed practically makes the wall a continuous one.

One-fourth of the basement only is excavated for heating and ventilating machinery. The steam supply comes from the general heating plant of the university.

Materials for Roofs of Different Pitch

In discussing the question of the various materials which are best adapted to different pitches of roofs a writer in a recent issue of *Contract Record* says: "It is extremely important that a roof material be adapted to the pitch of the roof. There is a certain limitation in this regard to the use of all roof coverings. Thus, roofs of slate, tile, unsoldered tin, etc., are used only on sloped roofs, whereas gravel and tar are applicable to flat roofs exclusively.

"If the pitch and the material are not properly related, leaky roofs are sure to result. The following table gives the desirable slopes that may be safely used with the roofs mentioned:"

Material	Rise of roof per ft.
Wooden shingles.....	6 in.
Slates	6 in.
Tiles	4 in. to 7 in.
Corrugated iron.....	4 in.
Asbestos shingles.....	3 in.
Tin plate.....	1 in.
Concrete	Flat
Tar and gravel.....	$\frac{1}{2}$ in.
Asphalt	$\frac{1}{2}$ in.
Ready roofing.....	1 in.

Casualties from Slipping and Tripping

Of vital interest to architects, builders and others concerned with the construction or maintenance of buildings is an address delivered by H. W. Mowery, safety engineer of New York City, at a meeting of the Philadelphia local of the National Safety Council, held recently at Franklin Institute. Through records from industrial commissions of four States and the coroner's office of New York City, he showed that an amazing number of casualties and an enormous cost for compensation, hospital and medical expenses, etc., are chargeable to the use of unsafe surfaces on which people walk or work. As the types of materials used are determined largely by the architect and the engineer, they can and should co-operate in the effort to eliminate many of the unsafe material conditions which permit these needless casualties and expenses.

He pointed out that more casualties than from

any other public industrial hazard are caused by slipping and tripping and yet less effort has been directed toward the elimination of this type of hazard than has been given to each of several others, which, combined, are less productive of casualties.

In the four years just passed there were 625 recorded fatalities in Manhattan from slipping and tripping. In 1914 and 1915 there was from this source a total of 298, while there were only 283 from elevators, fire and surface cars combined. The causes of slipping and tripping are unsafe material conditions.

In a certain large New York office building there was an average of nearly four accidents a week for a long period, caused while people were getting on and off elevator cars. Finally, the superintendent of the building installed at all floor landings a strip of anti-slip material about 8 in. wide along the entire bank of elevators. Since then there has not been a single fall reported.

On the main stairway of a railroad terminal there were twenty-one accidents in six weeks. Observations showed that people descending the stairs would slip on the metal nosing, the feet sliding forward and the front of the heel catching in one of the grooves throwing the person forward frequently striking upon the head. The treads were replaced by another type having anti-slip nosing and no heel-catching grooves. In the following three months not a single fall was reported.

Rigid Inspection Necessary

During actual construction rigid inspection should be made to provide for safe material conditions as well as the quality of workmanship and material entering into the project. It is much easier and more economical to remedy unsafe conditions as they are discovered than after the structure is completed. Moreover operating conditions during construction may be made more safe. Broken and uneven sidewalks, scaffolding and walk-ways in the work itself, also material dangerously piled, should not be permitted.

In New York State the Labor Law requires that in all factories over one-story in height "the stair treads shall be so constructed and maintained that persons walking thereon shall not slip." Within the past few months the same provision has been embodied in the New York City building code, and on Feb. 1 of the present year Pennsylvania adopted an amendment in regard to foundries to the effect that "all passageways and stairways, inclined runways, charging decks and platforms shall be properly lighted and shall have tread surfaces so constructed and maintained that persons walking thereon shall not slip or trip." The National Fire Protection Association has embodied the same provision in its specifications for standard buildings.

Other important bodies are awakening to the urgency of insisting that slippery surfaces shall be eliminated and that instead of slippery stone, glass, cement and especially iron and steel there shall be used some effective anti-slip material.

Each year the city of Buenos Aires gives a cash prize to the architect of what is adjudged to be the handsomest building erected during the year and the owner receives a worth-while tax exemption.

Outing of Chicago Builders' Club

An Annual
Is Greatly
the Members

ESTIMATE sheets and business worries were gently but firmly placed aside on Tuesday, July 11, by members of the Builders' Club of Chicago when they journeyed to Cedar Lake, Ind., for their twenty-first annual outing. The day was one that will be remembered for many months to come, as especially fine weather contributed much to the day's festivities.

SECRETARY TOM MANEY

Affair Which
Enjoyed by
of the Club

Inn, at Hammond, Ind. The members' mechanism also received satisfactory treatment at the State Line Inn, from which point the trip was continued without stop.

Binyon's Resort, at Cedar Lake, was reached shortly after one o'clock, when a quick retirement to the wash-room was made by the dusty travelers. After a leisurely clean-up, the dinner bell was anxiously awaited,

Group View of Members taken on Annual Outing of the Builders' Club of Chicago, Ill.

It was shortly before nine o'clock in the morning that the members gathered in the club rooms, in the Chamber of Commerce Building, and told stories prior to the start for the Hoosier resort. It was ten o'clock before the automobiles were self-started, each gaily bedecked with purple and white bunting, and pennants flying on either side of the wind shield. President James A. Green's car led the way south, down Michigan Avenue, and Chicago was soon left behind, though the breeze from Lake Michigan was present for the first hour. Human beings, like automobiles, need internal lubrication, so it was decided to make the first stop en route the Hammond Beach

and, when it sounded, the members filed into the dining room at 1.30. The specialty of the day was a chicken dinner, for which this resort is justly famous, and everybody did justice to a spread that would be hard to duplicate. Liquid refreshments were served during the meal, and, after coffee and cigars had been enjoyed, the members retired to the shady spots under the trees and told stories. Some of the pictures presented herewith indicate the surroundings under which the tales were recounted.

"Take things easy" was the order of the day. Accordingly, card clubs were organized beneath the

trees, and "hearts" and "poker" were indulged in. Among the parties was a congenial foursome in George Warren, Billy Scown, Joe Haigh, and Louis Beigler, the spectators in this region being Secre-

Charles H. Bishop, of THE BUILDING AGE, received the courtesies of the day from Secretary Tom Maney and George Warren.

On the return trip, Arthur Nollau's "Pierce-Arrow" lost its way, which made it necessary for his chauffeur, Frank, to hit the high spots to the extent of 53 miles per hour. The rest of the cars were caught, after a furious drive, near Hammond, where a stop was made before reaching Chicago.

Outing of Chicago Builders' Club—A Group of Past Presidents—Standing, Left to Right—T. Frank O'Connell, Harvey C. Knisley, James A. Green, Louis Binyon, and James A. Hogan—Seated—E. W. Sproul and Charles W. Gindele

tary Tom Maney, Arthur Nollau, Frank O'Connell, and T. B. Heinemann.

President Green also gathered a bunch together, in Harry Knisely, James H. Clark, and Jim Tuttle, and, according to all reports going the rounds, everybody was about even when hostilities were called off.

On the porch of a near-by cottage was the "big" game of the day, the participants being Charley Gindele, Bill McLoughlin, Jim Hogan, Bob Wilson, George Ruehle, and Michael McGovern. Jess, the waiter, was in constant attendance, and his celebrated combination, John E. Walker and H. I. Ball, was received everywhere with approbation.

John McLoughlin, the celebrated ladies' man, could not resist the temptation to take a swim.

The Beau Brummel of the day was George Ruehle, who dashed around in white shoes and hose.

E. H. Peters, of the L. J. Mueller Furnace Co., Milwaukee, Wis., was among those present.

There were numerous members present who are reverently referred to as "old timers," among them being Past Presidents Charles Gindele, T. Frank O'Connell, Harry C. Knisely, Louis Binyon, James A. Hogan, E. W. Sproul, and President James A. Green.

and included the principal items which go to make up the cost, such as walls, windows, floors, floor finish, stairs, toilets, and plumbing fixtures. The cost of excavation, heating, lighting, and elevators is so dependent upon each particular building that these items were omitted from the estimate.

Resting Under the Trees After Partaking of the Chicken Dinner

The assumed load on the floors is 150 lb. per square foot with column spacing about 18 ft. on centers and story heights about 12 ft. Mr. Anderson estimates the base cost on a building 50 x 50 ft.

Cost of a Concrete Building

Some very interesting figures on the cost of reinforced concrete buildings were presented in an address recently given before the Real Estate Exchange of Cincinnati by W. P. Anderson, president of the Ferro Concrete Construction Company of that city. While he realized that a good many items included in the cost of such buildings will naturally vary, he took as a basis a plan structure, with no fancy exterior decorations,

as about \$1.55 per square foot of floor space. If the building is 50 x 100 ft. this price would be reduced to \$1.20. If 50 x 150 ft. it would be \$1.12, and if 50 x 200 ft. it would be \$1.07.

In all these cases the building is assumed to be from four to ten stories high. A three-story building would cost somewhat more but the difference would be very slight. A two-story building would cost from 10 to 12 per cent more than these figures, and a one-story building from 15 to 20 per cent more.

A decrease in the width of the building would increase the cost so that for a width of 25 ft. instead of 50 ft. the unit cost would be increased from 35 to 45 per cent. If building widths are increased the costs would be correspondingly decreased.

The effect of increasing or decreasing the floor load depends on the height of the building. Obviously, there would be practically no change on a one-story building as the load comes directly on the ground. In a six-story building the decrease in cost for a 75-lb. load would be about 12 cents per square foot of floor space. This figure would also about equal the increase in cost if the live load was doubled.

The effect on the cost of varying the column spacing will not be great. Where columns are spaced about 15 ft. apart the cost will be about 6 per cent greater than where columns are spaced 25 ft. apart both ways.

In giving these estimates of costs for reinforced concrete buildings Mr. Anderson allowed for two stairways and one elevator tower for a building under 150 ft. in length, and two stairways and two elevator towers for greater lengths. Two plumbing fixtures per floor were allowed for the first 5000 sq. ft. and one additional fixture for each additional 5000 sq. ft. No allowance was made for any interior partition work except that which would be necessary around stairs, elevator shafts and toilets. Of course, these estimates are based on plain factory buildings, and any attempt at decoration would naturally increase the cost.

The percentage of window area to wall area would have but little effect on the unit cost of the building. In figuring the estimates given a steel sash window with ordinary glass was used. If wire glass was found necessary the cost would be considerably more than for plain wall.

Bank Building to Be Remodeled

The contract has been let by the Vineland National Bank, Vineland, N. J., for the remodelling of its building to Hoggson Brothers, New York. The remodelled building—a clever adaptation of the Georgian period of architecture—will be constructed of brick, with marble trim and granite base. Four white Vermont marble pilasters, across the front of the edifice, will give evidence to the element of strength characteristic of the banking business. The banking room will be finished in oak and mahogany with a counterscreen of Botticino marble and base of light Bougardt, surmounted by handsome ornamental grilles.

New building ordinances have just been adopted by the towns of Sanger, Cal., and Mesa, Ariz.

Tenement House Construction in New Jersey

Figures have just been issued by the Board of Tenement House Supervision of New Jersey covering the number of plans of new buildings approved during the first six months of this year, also those for the corresponding period of 1915. The total for the six months just ended shows 404 new buildings to have been approved, estimated to cost \$5,808,000, while in the first six months of last year plans for 418 buildings were approved, estimated to cost \$5,290,000. The alterations were \$164,500 in the former case, and \$164,500 in the latter case, this bringing the two totals to \$5,972,500 and \$5,455,700 respectively.

Municipalities	Jan. 1 to June 30, 1915		Jan. 1 to June 30, 1916

Alterations	157	165,700	145	164,500
Total	575	\$5,455,700	549	\$5,972,500

As might naturally be supposed, the greatest number of plans were for new buildings in Jersey City, but while the falling off in plans filed in the first six months of 1916 was appreciable as compared with the corresponding period last year there was less than \$100,000 difference in the cost in the two periods. Newark also showed a heavy falling off, both in the number of plans approved and the estimated cost of improvements. On the other hand, Atlantic City, Bayonne, Orange and Passaic showed appreciable gains over the first half of last year.

It is stated that Virginia, in 1612, produced the first bricks made in the United States.

A Unique Architectural Scheme in Building Construction

A rather unique architectural scheme is nearing completion in the business section of Lake Forest, Chicago, involving as it does, the erection behind a curtain of old business fronts, a number of stores which in their general scheme are an adaptation from old English and German towns. One structure known as the West Building is typically Italian in its architecture.

The buildings directly west of the Chicago & Northwestern railroad station, are grouped about a court, through the middle of which runs a park dedicated to the city. At the entrance to the park will be an ornamental stone fountain. At the opposite end is the white colonnade of the West building, while on either side are the lines of symmetrical brick and stucco store buildings, a general view of which during the progress of the work is shown herewith.

The outstanding feature of the group is the two towers, following the style of the old towers of

in the plans of five dwellings to make the garages proposed for the basement conform with the new requirement.

Before issuing the rule Mr. O'Sullivan determined the character of the regulations in the matter of garages under inhabited buildings in twelve other cities. In but two instances, St. Louis and Cincinnati, did the replies indicate that there were no restrictions of any kind on this subject. A majority of the remaining cities made the entrance the only opening in the fireproof room, while the other permitted the construction of a fireproof door leading into other parts of the house. Because of the danger of this door being left open and thus destroying the precaution against fire found in the fireproof construction, Mr. O'Sullivan decided upon the more stringent requirement as the safest.

Six Months Building in Manhattan, New York

The figures covering building operations in the Borough of Manhattan, New York City, for the

Court of New Building in Lake Forest, Ill., Near Completion Behind the Old Business Section Which is Being Razed

Munich and Nuremberg. The sun dial tower, forming a part of the north building, rises to a height of 90 ft. while the clock tower opposite it, in the south building, is 70 ft. high.

There are twenty-eight stores in this block, the interiors of which are in harmony with the architectural treatment of the exteriors. In connection with the project it is interesting to note that Berger's "Classik" Steel Ceilings were used in all the stores.

New Rule for Garages in Private Houses in Louisville

Under a rule recently issued by William J. O'Sullivan, Building Inspector of Louisville, Ky., no permits will be issued for residences with garages in the basement unless the plans contemplate making the garage absolutely fireproof, with but one entrance, and that from the outside. Under the rule the department has already required changes

first six months of the current year, show that new construction work has been planned upon a scale far in excess of that for the corresponding period of 1915. Most of this increase is due to the pronounced activity in the second quarter of the year when the building season was in full swing. The totals compiled by the Superintendent of the Bureau of Buildings, showing the various classes of buildings projected, constitute some striking contrasts with last year. In the case of tenement house construction, permits were issued in the first six months of this year covering 116 buildings estimated to cost \$18,464,000, while in the same period last year, permits were taken out for 98 buildings involving an outlay of \$9,982,500. Another item showing a heavy increase this year is that of hotels on which plans were filed for 14, estimated to cost \$15,827,000 as against 5 hotels costing \$1,128,000 in the first half of 1915. Of office buildings, permits were taken out for 20 this year, estimated to cost \$4,125,500, as against 11

in the first half of last year involving an estimated expenditure of \$3,625,000. While private houses are not being built at the present time to the extent they were many years ago, 18 were planned in the first half of the current year estimated to cost \$1,343,200, while in the same period last year, only 5 were planned estimated to cost \$405,000.

The falling-off in the amount of capital put into store and loft buildings, which was greatly overdone a year or two ago, is strikingly shown in the figures for the two periods under review. In the first six months of 1916, plans were filed for 36 such buildings estimated to cost \$3,527,000, while in the first six months of last year, plans were filed for 45 such buildings involving an estimated outlay of \$10,473,500.

In the first half of the present year, 16 places of amusement were planned, estimated to cost \$1,824,500, while in the corresponding period last year, 15 such buildings were planned to cost \$960,250. There were two hospitals planned this year to cost \$1,000,000 as against five a year ago to cost \$560,000.

The estimated cost of the new buildings projected in Manhattan during the first six months of 1916 is placed at \$52,363,895 with alterations costing \$10,647,335, making a total of \$63,011,230. In the first half of 1915 the new buildings for which permits were issued were estimated to cost \$39,638,720 and alterations costing \$5,082,290, or a total of \$44,721,010.

Chicago's Mammoth Recreation Pier

The municipal recreation pier now rapidly approaching completion on the waterfront in Chicago, Ill., may justly be classed as one of the Seven Wonders of the World. Although the pier is built largely of concrete and steel, millions of feet of lumber were used in its construction. Doubtless few people, excepting those directly concerned, have had any idea of the enormous quantities of material of all kinds used, of not only lumber, but of the other component materials.

The pier is 3,000 feet long, extending out into the lake directly east from the foot of Grand Avenue and just north of the mouth of the Chicago river. It is particularly easy of access to the general public owing to the fact that any north and south line of street cars will transfer to the Grand Avenue Lake Shore line, which runs through the interior of the structure to within about 700 feet of the lake end. It travels on the second floor of the pier, turning at the east end and having ample accommodations all the way around the interior loop, about 5,000 feet in length, for receiving and discharging passengers.

Quantities of lumber used were:

	Feet
Board walk (Douglas fir).....	250,000
Sheet piling (Douglas fir).....	4,500,000
Bumper plank, freight dock (oak).....	25,000
Concrete forms (yellow pine).....	1,800,000
Creosoted blocks (yellow pine).....	1,350,000
Planking, trestles, etc. (sundry woods).....	50,000
Hardwood flooring (maple).....	26,000
Total	8,001,000

In addition there were 23,000 pieces of piling, 40 to 60 feet long, which, if reduced to board feet, would make at least 6,500,000 feet more.

The Reconstructed City

The above is the name of an exposition now being held in Paris for the purpose of teaching, even at this early date, how to rebuild war-wrecked portions of northern France, when the appalling conflict now in progress is ended. It is a French exposition entirely and America's part has been only in the sending by lumber manufacturers of an exhibit showing the possibilities of American timber in this work of reconstruction.

"The Reconstructed City" is in several sections, some of which are devoted to city residence construction, city industrial buildings, city planning, rural work, etc. In some cases the city planning department will work for an entire reconstruction on altogether new lines of the cities which have been wrecked by bombardment. In other cases only building construction along the old streets will be required.

The Southern Pine Association, through its European agent, has an exhibit not only of southern building types but of typically American structural work. The American lumber men have a series of models for buildings for city and farm, including a small "mill-construction" building for industrial purposes, and models of farm building, such as an ideal barn, poultry house, granary and piggery. Photographs of groups of these buildings are included and the balance of the exhibit is made up of samples of Southern Pine in various stages from the original timber to the finished lumber. One of the unique features of the exhibit is a relief plan of an ideal farm with model buildings properly placed and landscape effect with hills in relief, streams, roads, etc.

Shortage of Timber in Holland

At a meeting in Amsterdam of an association of employers and workmen in the building industry, gloomy reports were made regarding the supply of timber for building purposes, says United States Consul Frank W. Mahin, writing from that city. Holland has more woodlands than most foreigners suppose, but they are far from sufficient to supply the needs of the country for building timber, and without imports from other countries few houses could be built in the Netherlands.

In the opinion of the association of builders the situation is serious. Timber is now imported from Germany, Sweden and Norway. The quantity obtainable is small, and most of it is of inferior quality. Continued supplies from Germany can not be relied upon, the association believes, as the German Government has need of the surplus timber and will pay a higher price than this country has paid.

The building association gives warning that unless relief measures are taken the supply of wood most needed for construction work will be exhausted within a few months and great stagnation and unemployment in the building trades may be expected. Already several woodworking factories have ceased operations.

This situation suggests that American manufacturers and exporters of building materials might profitably give renewed attention to the Dutch market, with a view to both the present and the future.

New Publications

Indication in Architectural Design. By David Varon. 150 pages, size 9 x 12 in. Illustrated by freehand pencil sketches. Bound in cloth. Published by The Wm. T. Comstock Co. Price \$5.00.

One of the most valuable mediums of instruction in architectural schools is the clever pencil of the professor of design, and the author of the work under review has taken advantage of this fact to compile a book which is in reality a course in architectural elements and composition introduced through the medium of freehand pencil sketching. This method tends to develop a sense of proportion and provide a fund of ideas which tend to make the architect thoroughly capable of thinking in three dimensions and increase his power of visualization, the lack of which is a common fault in architectural designing.

The author has not prepared his material with the idea of making it a copy book, but to show the student the steps by which an individual technique may be formed; in other words, how to develop original thoughts and conceptions which shall be of artistic value. To aid in this a simple console is taken, for instance, and shown in a number of different forms, all with the original fundamental idea. The author's training at the *Diplômé Ecole des Beau-Arts* and as Professor of Architectural Design at Syracuse University and at the University of Illinois has well fitted him to contribute valuable ideas along these lines.

The book has a preliminary section of 48 pages devoted to "Analysis of Simple Elements—Training the Eye and Hand," "Analysis by Sketching," "Silhouettes," "Indicating," or the art of picturing ideas by a few simple strokes of the pencil; "The Application of Indicating to Research Work and Analysis," "Elementary Elevation Design," "Design of Elevations Involving Salient Features," "Planning," "Solving a Problem." The rest of the book contains fifty full-page plates with explanatory notes along the lines suggested by the chapter headings.

Estimates, Cost and Profits. By F. N. Vanderwalker. 120 pages, size 5½ x 7½ in. Bound in cloth. Published by Text Book Co. Price \$1.

Efficiency is the slogan of the business world of to-day and nowhere is it of greater importance than in the field of estimating. Almost every job done requires an estimate, and the book under review contains valuable information regarding the proper method of preparing estimates for house painting and interior decorating. The author is head of the Paint Information Bureau of Carter White Lead Co. and has, therefore, had opportunities to become acquainted with all classes of work along these lines. The book contains a halftone engraving of an average house, and from this illustration the reader is shown how to estimate area, labor and materials. Next, a set of blueprints of a bungalow forms the foundation for an estimate prepared directly from them. As the author takes up the different features of the work, his comments on estimating according to the finish or color are instructive and illuminating. There are separate chapters explaining important parts of the work to be done.

But not all the profits of a business disappear through incorrect estimates. Many a dollar is wasted in the shop by lack of system and unless a high percentage is added to each job for overhead expense the contractor is ever apt to lose money, and if the percentage is added the estimate is likely to be pretty high. Therefore the chapter on "The Modern Paint Shop and Its Management," is especially valuable along these lines, for the reader is shown how to keep his overhead cost down as well as how to figure it.

Brick Homes at Low Cost. 30 pages, size 12½ x 9¼. Illustrated by plans, photographs and drawings. Paper covers. Published by Society Advocating Fire Elimination. Price 50 cents.

With the idea in mind of popularizing the construction of low cost brick houses, the Society Advocating Fire Elimination compiled the above mentioned book for a number of manufacturers who supported the face brick exhibit at the First American Complete Building Show, held in Cleveland, Ohio, in February of the current year. The work contains plans and drawings of 10 houses ranging in price from \$2,500 to \$5,000, together with a two-family house and a bungalow, also a Typical Specification. Bids from three reliable contractors are given for each house, together with the number of brick necessary. The houses were specially designed for construction in brick by George W. Ritchie, for several years architect for the Board of Education, Cleveland, Ohio.

Property Owner Not Responsible for Injuries to Contractor's Workmen

The Supreme Court of the State of California recently held that a property owner is not responsible for injury to a contractor's employee working on his property. This decision virtually invalidates that part of the workmen's compensation act which empowered the State Industrial Accident Commission to enforce compensation claims against a property owner as a "principal" if he let work on his property entirely to a contractor.

As many contractors are financially unable to satisfy judgments in favor of injured workers, and as this holding will be unfair to those contractors who are financially responsible, an effort will be made to appeal or to secure remedial legislation.

New Building Ordinance for San Diego, Cal.

At his own request, Building Inspector J. E. Fifield of San Diego, Cal., has been authorized by the city council to draft a new building ordinance. He will be assisted by a number of architects.

According to official reports just compiled forest fires burned over something less than 300,000 acres of National Forest land in 1915, the timber loss being 156,000,000 board feet valued at \$190,000. Although the season was regarded as one of unusual exposure owing to delayed fall rains, the loss was materially below the average for the last five years.

Brief Review of the Building Situation

Building Operations for June in 114 Cities Show
an Increase of 30.3 Per Cent Over June, 1915

DURING the month of June, new construction work was projected upon a liberal scale in all sections of the country, the amount of capital involved in 114 cities showing a gain of 30.33 per cent over June, 1915. Of the cities reporting, 86 indicated increased activity, while 28 show a falling off in the value of the improvements for which permits were issued.

In the Eastern section of the country, 42 cities reported an increase of 34.3 per cent over June a year ago, the gain in New York City being especially marked. The unusual increase in the Borough of Manhattan is doubtless due in part, at least, to the action of many builders in forestalling the impending restriction on the heights of buildings, and the contemplated zone measure, both of which are expected to soon become a law, by placing on record plans for large buildings, many of which may not take tangible form for a long time to come. The filing of such plans was particularly noticeable the latter part of the month and during July. The accompanying table shows the changes in Eastern cities in June compared with June, 1915.

CITIES OF EASTERN STATES

	June, 1916	June, 1915
Albany	307,455	359,405
Allentown	165,730	151,780
Bayonne	102,594	32,784
Binghamton	175,123	155,208
Boston	5,634,000	5,628,000
Bridgeport	523,300	779,899
Brockton	256,905	83,257
East Orange	112,398	66,739
Elizabeth	251,464	109,614
Erie	353,989	155,254
Harrisburg	126,155	221,950
Hartford	814,703	462,523
Haverhill	135,500	94,150
Hoboken	16,480	64,140
Holyoke	146,250	93,015
Irvington	68,640	42,755
Jersey City	698,076	519,958
Manchester	137,702	316,917
Newark	1,438,756	770,884
New Bedford	210,925	201,150
New Haven	257,580	451,025
New York:		
Manhattan	18,322,110	4,392,190
Bronx	2,322,278	1,286,041
Brooklyn	4,102,609	4,526,677
Queens	1,346,141	1,744,075
Richmond	523,362	316,781
Passaic	163,520	61,940
Paterson	121,114	313,748
Philadelphia	5,147,115	3,878,850
Pittsburgh	940,762	1,212,472
Quincy	269,139	130,612
Reading	69,750	152,900
Rochester	662,042	969,632
Scranton	228,086	143,491
Schenectady	118,493	91,883
Springfield	898,918	451,538
Syracuse	552,995	414,119
Trenton	286,249	486,267
Troy	55,753	93,475
Utica	129,725	272,400
Wilkes-Barre	117,351	58,111
Worcester	660,152	348,148

In the cities of the Middle West or central portion of the country the gain as compared with a year ago has been quite marked, 35 cities showing an increase of 26.9 per cent. Unusual activity is to be noted in Akron, Chicago, Detroit, Cleveland and Minneapolis.

CITIES IN MIDDLE STATES

	June, 1916	June, 1915
Akron	1,323,455	355,225
Cedar Rapids	291,000	135,000
Canton	336,945	135,670

Coming now to the extreme Western section of the country and including cities no farther east than Denver, we find a gain of 35.9 per cent over June a year ago. Increased activity is noted in Los Angeles, Oakland, Portland, Denver, Sacramento. San Francisco and Tacoma, while cities showing a falling off as against a year ago are Seattle, Spokane and Pasadena.

For the first six months of the current year the amount of new construction work planned has been considerably in excess of that for the corresponding period a year ago, and the outlook continues to be of a most encouraging nature.

Current News of Builders' Exchanges

Meetings and Outings of Various Bodies Throughout the Country—Banquet of Los Angeles Exchange

Picnic of the Pittsburgh Builders' Exchange

THE members of the Builders' Exchange of Pittsburgh, Pa., held their annual outing and picnic at "The Pines," on the Perrysville Road, on Thursday, June 29, the day being ideal and the attendance large and enthusiastic.

The feature of the afternoon was a ball game between the Builders and the Dealers in Builders' Supplies. The captain of the former team was John L. Richmond, and the captain of the Supply Dealers was Hugh F. McKnight. The Builders were conspicuous in the use of the bat, and some hard hitting was a feature, the game being won by the Builders by a score of 15 to 4. Home runs were made by John Richmond and Lawrence Ley.

After the ball game there was a tug of war, which also resulted in a victory for the Builders. The Supply Dealers not being satisfied with the first pull, a second was arranged, and this was also won by the Builders.

After the tug of war there were a series of races, including a 100-yd. dash, free for all, a 50-yd. dash for ladies, a sack race, a three-legged race and a fat men's race. There was also an egg and spoon race for ladies.

After the races a delicious supper was served in the spacious dining room at "The Pines," and consisted of fruit cocktails, fried chicken, waffles and maple syrup, mashed potatoes and green peas, salad, ice cream and coffee. After dinner every lady received a box of choice candy and every gentleman a good cigar.

At 9 o'clock there was an elaborate display of fireworks and from that time until 11 o'clock the guests indulged in dancing.

The members of the committee having charge of the affair made it their business to see that every guest had a good time. In addition to the amusements mentioned a number of the guests pitched quoits, others played cards, and others rambled over the large grounds which form an adjunct of "The Pines."

Altogether the picnic of the Builders' Exchange was one of the most enjoyable entertainments ever held by that association. The committee in charge divided the work. W. E. Goldman, chairman, had charge of the arrangements for serving the dinner; A. C. Kahn looked after the refreshments on the grounds; H. B. Lauderbaugh had charge of the music; P. A. Kinley arranged for the fireworks display, and H. H. Gilmore was in charge of the ball game and the various races.

Banquet of Los Angeles Builders' Exchange

Members and their friends of The Builders' Exchange of Los Angeles, Cal., to the number of about 200, filled the banquet hall at the Elks' Club in that city on the evening of June 15, on the occasion of the annual banquet. The new officers were installed with little formality, most of the evening being given to enjoyment of the dinner and after-dinner speeches. L. J. Pozzo, the "contralto contractor," furnished a cabaret entertainment, and led the diners in numerous songs.

M. A. Berne was toastmaster, and the principal speakers were: J. H. Bean, president; Architect John C. Austin, Federal Judge B. F. Bledsoe, Rev. Baker P. Lee, W. H. Booth and S. L. Weaver.

The speech of most trade interest was that of Mr. Bean, who stated that Los Angeles in the past two years had done more building than any city of its size should have done, probably 50 per cent of the buildings being designed by other than certified architects; that

many people gave less attention to the construction of their buildings than to the design of a suit of clothes, and that it was becoming urgently necessary for contractors, builders and architects to unite in a campaign of education.

Annual Meeting of Baltimore Exchange

The annual meeting and election of officers of the Builders' Exchange of Baltimore, Md., was held at the Emerson Hotel on Tuesday, June 20. There was a large turnout of members and the occasion was one of unusual interest. The officers chosen to serve for the ensuing year were:

President.....A. J. Dietrich.
First Vice-president.....C. Morgan Marshall.
Second Vice-president.....John Trainor.
Third Vice-president.....William F. Chew.
Treasurer.....S. Frank Bennett.
Secretary.....I. H. Scates.

There were also elected four directors, namely: George R. Bullen, Willard E. Harn, J. J. Kelly, Jr., and H. J. West.

Mr. Dietrich, who succeeded Herbert J. West as president, is a member of the structural iron firm of Dietrich Brothers, one of the leading firms of its kind in that section of the country. The re-election of Mr. Scates as secretary for the tenth term shows the esteem in which he is held by the membership, and his administration during the past nine years has met with an unusual degree of success, resulting in the local organization becoming one of the leading trade bodies of its kind in the country.

After the meeting there was a dinner at which several short talks were made by members, the topics being of interest to members of the organization. The speakers included Secretary I. H. Scates, F. S. Chavannes, W. E. Harn and Joseph P. Tully.

Retiring President West was given a handsome flat silver service as an expression of appreciation of his labors in the interest of the organization, the presentation being made by Joseph P. Tully on behalf of the members of the exchange.

Outing of Detroit Builders' Exchange

According to previously announced program the members and friends of the Builders & Trades' Exchange and the Michigan Society of Architects, Detroit, Mich., enjoyed the joint annual outing of the associations at Put-in Bay, Ohio, on Wednesday, June 28. There were something like six hundred on the trip, which was greatly enjoyed by all present. An orchestra furnished popular music and the dancing floor of the "Put-in-Bay" was crowded most of the time. Another feature of the trip greatly enjoyed was the American Hawaiian Trio, supplied by the George H. Clippert & Brother Brick Company.

The real excitement of the trip was centered in the contest for a five hundred dollar garage. Each adult person on board who held a Builders & Trades' Exchange coupon was entitled to one guess as to the number of nails contained in a glass jar displayed upon a table. The person guessing nearest the actual number of nails contained in the jar by actual count of a committee selected for the purpose was to be awarded the garage in question. There were also ten other prizes

awarded in the test. The winner of the garage, as announced on the return trip, was E. R. Gloetzner.

There was also a contest by the United Fuel & Supply Company. Buttons bearing a number were given out and each bearer was to find two other buttons with the same number as his own. The prize was an electric flashlight to each of the three persons.

The members and their friends arrived at the island a little after noon and immediately had dinner. At 2 o'clock a game of baseball between the Contractors and the Architects was commenced. Only four innings were played, the score standing at that time 11 to 6, in favor of the Contractors. After the ball game some visited the caves, others went sightseeing, and others enjoyed themselves at the dance pavilion. At 5.30 the boat started on its return trip. Music and dancing occupied the evening until the steamer reached the dock.

The Dallas Builders' Exchange

An interesting feature of the exchange program has been the weekly educational meetings. At the gathering at the Elite Café on June 21, Judge W. F. Ramsey, chairman of the Board of Directors of the Dallas Federal Reserve Bank, advised the sixty members who were present to "Give honest work and charge enough to realize a fair profit." The judge pointed out that "competition is the life of trade and mutual co-operation the keynote of success. It is highly important that contractors figure in their contracts an amount to cover overhead expenses. It does a contractor little good to obtain a contract and make no profit on the job."

At another meeting, also held at the Elite Cafe, D. E. Humphry of the Southern Wire & Iron Company, Dallas, made a very interesting address, the subject being "Services Required of Iron Works." He pointed out that the reason there is so much room at the top for iron works which give real service is because of a lack of knowledge of the first principles of service. "The Builders' Exchange," he said, "stands for many principles, both local and national. There is not a material man or a contractor who does not need its services. The exchange has an open door for the new contractor and material man coming among them. The contractors and material men of Dallas and of Texas are not afraid of fair competition. We want industries to come to Texas to stay, and we want all to join the exchange."

Membership Campaign of Flint Exchange

The membership campaign of the Builders & Traders' Exchange of Flint, Mich., which has been in preparation for some weeks, was launched at the bi-monthly meeting held at the end of June. It is hoped that at least 250 members may be added to the roster of the exchange, and when sufficient members have been secured larger quarters will be established. It is also expected that in the course of time a permanent building exposition will be inaugurated, somewhat similar to those which are features of many of the other builders' exchanges throughout the country.

The exchange has decided to co-operate with E. J. Friar, sealer of weights and measures, to have an ordinance passed to control the sale of sand and gravel in the State, so as to insure the purchaser receiving full measure.

Outing of Twin City Builders' Exchanges

The members of the Builders' Exchanges in Minneapolis and St. Paul enjoyed the fourth annual outing of these organizations on July 22 at Wildwood, White Bear Lake, Minnesota's famous picnic resort. A very interesting program had been prepared for the occasion, including a baseball game between members of the St. Paul Builders' Exchange and those of the Minneapolis Exchange; a tug of war and a game of water baseball between representatives of the two organizations. There

were running races, tub races and swimming races for men, a spoon and potato race for the ladies and running races for children.

The committee having charge of the outing issued a week or more in advance of the event a striking poster printed in colors and calling attention to the various features which had been provided.

Meeting of Reading Builders' Exchange

At a recent meeting of the Builders' Exchange of Reading, Pa., the feature was an address by former Mayor W. E. Weimer of Lebanon, chairman of the State Building Code Commission. The speaker explained the code drafted by the commission and told of the campaign waged for buildings not to exceed 125 ft. in height, and the success experienced in having the plan adopted in numerous communities.

New York's Board of Standards and Appeals

In connection with the efforts which are being made to simplify building inspection in New York City, Mayor Mitchel on July 11 appointed several members of the new Board of Standards and Appeals, created by the Building Inspection bill passed by the last legislature. Rudolph P. Miller, who resigned as Superintendent of the Bureau of Buildings for the Borough of Manhattan to take part in the revising of the Building Code, has been appointed Chairman of the new Board. Lansing C. Holden, a member of the American Institute of Architects, is appointed to represent the architects; Howard C. Baird, a member of the American Society of Engineers, will represent the structural engineers; William Crawford, President of the Building Trades Employers' Association, will represent the building trades, and Alfred R. Kirkus and Alfred J. Boulton will represent the Brooklyn building trades.

Daniel Sullivan, formerly Secretary of the Bureau of Buildings, has been made Secretary of the new Board, which, it may be remarked in passing, takes the place of the Board of Examiners.

Important Amendment to Tenement House Law

The attention of architects, builders and others interested in tenement property has been called to the fact that the Tenement House Department of New York City is now empowered to issue foundation permits before the approval of the complete plans for the erection of a tenement house.

New Mechanics' Lien Law

Important amendments to the mechanics' lien law of New York have recently been added, which provide a workable method whereby any building operation which gets into difficulties can, by the co-operation of 75 per cent in amount of mechanics' lien creditors, be completed, without interference from other liens, judgments, attachments or other proceedings.

CON-SER-TEX

Solves All Roofing Problems

Investigate the merits of this roofing material. Its claims for your consideration are based on the following facts:

- Costs very little.
- Is easy and inexpensive to lay.
- Makes a neat, smooth, durable surface.
- Will not leak, rot, stretch or shrink.
- All this is explained in our new illustrated booklet, "Roofing Facts and Figures." Send for a copy.

CON-SER-TEX is a specially woven canvas roofing which is chemically treated to preserve the fibre from mildew and the detrimental action of the oil in paint. It is water-proof, weather-proof, rot-proof and wear-proof. When properly laid it will last as long as the house itself. Contractors, builders and carpenters in all parts of the United States continually express their satisfaction with this material when used for roofings, porch decks, sleeping balconies and bungalow construction. It is furnished in such widths and weights as are best suited for various classes of work, thus practically all waste is eliminated.

Economical Serviceable **CON-SER-TEX** *Attractive Profitable*

Certainly the above facts are of sufficient interest to justify your immediate request for samples, prices and complete information. Better write today before you forget it.

The Handsomest Roofing You Can Use Asphalt Shingles

These Beautiful Colors Add Charm To The Roof

Rich looking shades of red, green, gray and brown are possible when you roof with Asphalt Shingles. By using them you can give the houses you build as beautiful an appearance as though the cost were a thousand dollars or so greater.

With this roof beauty goes a thorough protection against the elements that is maintained year after year because this roofing *stays young*. It does not dry out or change. It is just as permanent as the unchangeable color of its surfacing of crushed slate or rock products. Water cannot get through a single layer no matter what the conditions. Yet these shingles form a *triple thick* layer that means three fold protection.

We have a book of new ideas on roofing from which you can get many suggestions that will aid you. Write for your copy of "The Roof Distinctive."

Your Customers Will Like Asphalt Shingles Better

There is a strong appeal in Asphalt Shingles that will interest your customers. They will be quick to see the advantages of a roofing that is handsome, leak proof and repairless. You will have a still greater measure of their confidence for having suggested them.

Every standpoint of roofing value is covered by Asphalt Shingles. From every standpoint of yours, too, they are better. You can apply them faster and at less cost for labor.

They are so much better looking that they make the house you build even more attractive than others near it which are covered with a drab-looking, ordinary roof.

Our other new booklet, "Fire Protection," shows some remarkable tests of various roofings. Proves which roofing gives best protection. Copy sent free on request.

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Improvement in Morgan Doors

The Morgan Company of Oshkosh, Wis., Chicago, Ill., and Baltimore, Md., makers of Morgan doors and mill-work, has just added another important feature in the building of its doors. In place of the old straight dowel it has acquired the right to use the wedge dowel, which is claimed to be the last word in door construction. The dowel locks stiles and rails together with so tight a

Improvement in Morgan Doors—Fig. 1—Showing the Manner in Which the Dowels Are Used

grip that there is not the slightest chance that they can come apart. The fact that Morgan doors are made with an all-white pine core renders them especially suitable for the use of this new device. The wedge dowel is made of hard wood with two oblique slits at each end, as shown in Fig. 1. When the stiles and rails are clamped together the wedge formed by the slits is broken loose and forced back against the dowel, so as to expand the sharp ends, which are, by the pressure of the clamping machine, driven into and embedded in the soft white pine core. The illustration gives an idea of the manner in which the ends of the dowel are forced apart by the wedges and also the spreading that takes place in the sharp ends when they are driven into the core. There are two grooves along the dowel to assure an even spread of glue along the dowel and to prevent any glue or air pockets forming at the end of the dowel. At the conclusion of the clamping operation the holes are filled by the dowel with just enough glue to make a perfect bond between the dowel and the core.

The Double-Surfaced Neponset Shingle

There has recently been placed upon the market by Bird & Son, East Walpole, Mass., a shingle which is said to be an outgrowth of the built-up Neponset twin shingle, but contains features not found in the maker's original shingle. It is known by the name indicated by the above title, and retains the twin shape which is characteristic of all Neponset shingles. The new product is said to consist of a layer of high-grade asphalt felt, which has been thoroughly saturated with asphalt. To the surface of this is added an asphalt coating in the regular way, and into this coating is rolled a solid surface of crushed rock. The next process is the application of a solid coat of asphalt over the rock surface, and then into it is rolled a final surfacing of crushed slate, rather fine in texture and of a high color—red or green. This treatment, it is claimed, results in a very attractive surface and a color that is entirely distinctive. The composition of the shingle is such as to make it extremely flexible, the claim being put forth that it will bend without breaking and will, therefore, lie flat on

the roof. It is referred to as being especially adapted for use over a curved hip, or other similar place. By reason of its twin form the shingle can be laid in much less time than that required for ordinary shingles. The new shingle is 20 in. wide instead of 16 1/16, as was the original Neponset, yet it is not too large to prevent its being easily handled by one man. Three nails to a shingle are used, and by reason of the special Neponset cut-out the spacing is automatically taken care of in laying. We understand that a sample of the new shingle may be obtained by any architect or builder upon application to the company.

Iron Bench Planes with Automatic Set

With a view to meeting the demand for a plane which will save the time of the carpenter in setting the cutter and cap, Sargent & Company, 53 Water Street, New Haven, Conn., has just placed on the market a line of iron bench planes, a view of one of which with the knob is shown in Fig. 2. These new planes are made with a single cutter instead of double or spring cap cutter commonly used in connection with iron planes. The most important feature of the new plane is found in the construction of the clamp, which combines the cap and clamp found on the spring cap type of planes. The clamp can be adjusted by means of a regulating screw to whatever point is suitable for the class of work on which the mechanic is using the plane. For a coarse cut he raises the clamp, thus leaving a considerable space between the extreme lower end and the cutting edge, while for a fine cut he reduces this space to a minimum. When the clamp is removed so that the cutter may be ground or honed it will always drop back into its original position without further adjustment, which of course means a considerable saving of time for the

View of the Knob Showing Range of Adjustability

Fig. 2—Sargent's Iron Bench Plane with Automatic "Set"

carpenter. The planes are made in six sizes, namely: Smooth planes, Nos. 707, 708, 710; jack, No. 714; fore, No. 718; jointer, No. 722; the terminal figure indicating the length of the plane. They are made with both smooth bottom and corrugated bottom, the terminal letter "C" being added to the above number to indicate the corrugated.

On the larger sizes, Nos. 718 and 722, there is an

added feature, consisting of a high knob on the front of the plane which is adjustable to permit the user to change his grip on the plane when for any reason he becomes tired after constant use. It also enables the user to swing the knob to the right or to the left to avoid any possible obstruction. These planes are adapted for use on cross-grained hard wood, but the maker states they can be used to equal advantage on soft wood. The fact that they are light in weight makes them particularly convenient for the journeyman carpenter.

A Book on Waterproofing

The Ceresit Waterproofing Co., 110 South Dearborn Street, Chicago, Ill., has issued an interesting 24-page booklet which explains in detail when, how and what waterproofing to use. It is said that every class of construction requires waterproofing in some form, for dampness is a destructive force from which no locality is exempt, no materials escape and no conditions evade. The company manufactures six waterproofing compounds. The first is a plastic paste to be mixed with water used to temper concrete, cement mortar or cement stucco. Ceresitol is a liquid which may be applied with a brush for damp-proofing brick, cement blocks and

absorptive action of brick. The results also tended to demonstrate to the user the ideal mortar for laying up brick masonry. The statement is made that maximum strength with minimum expense in laying brick masonry can be obtained with a mortar mixture composed of $\frac{1}{2}$ cu. ft. of Portland cement, $\frac{1}{2}$ cu. ft. of hydrated lime and $\frac{3}{4}$ cu. ft. of sand, or a 1:1:6 mixture. The Bulletin describes the mortars used in the investigation and the proportions in which they were mixed together with a summary of ultimate resistances, the results of the tests and a discussion of the results. Numerous pages are devoted to diagrams showing compression tests, all of which are of special value to the architect, the builder and the owner.

Economy Methods in Concrete Foundation Work

The economy of low charging and portability of a concrete mixer in building foundation work is shown in the methods used in connection with the construction of a three-story and English basement, fifteen-flat building recently completed for F. J. Campbell at Dorchester Avenue and Sixty-seventh Place, by Bundo Brothers, contractors, 938 East Seventy-fifth Street, Chicago, Ill. This firm of contractors makes a specialty of concrete foundation work for buildings and mix all

of their concrete in a 12-cu. ft. "Standard" low charging concrete mixer. Fig. 3 of the illustrations shows the mixer in operation on this job. Another mixer of the same kind is shown in use in the construction of the foundations of an adjacent building.

In this work there were 5177 cu. ft. of concrete in the footings and four foundation walls. The time required to construct the "forms," mix and place the concrete was 42 hours, and the cost for setting "forms" and pouring concrete was $2\frac{1}{4}$ cents per cubic foot. Bundo Brothers employed only five men to operate the mixer, the remainder of their force being engaged in setting "forms" and other work. Two men are employed to deliver material to the mixer and three were required to wheel the mixed concrete to the "forms." The usual size of batch mixed was 10 cu. ft., but the contractors say that they

Economy Methods in Concrete Foundation Work—Fig. 3—View of "Standard" Low Charging Mixers on the Job

porous stone of any kind. It leaves no film and does not in any way affect the color of the treated surface. Another product is a permanent damp-proof protective and bonding material to be applied to the interiors of exposed walls before the application of plaster. It eliminates furring and lathing. A heavy, black, asphaltic material is also made for application to outside foundation walls for protection against dampness. A floor hardener is a ground metallic material capable of giving concrete floors a permanent wearing surface and to prevent dusting. This is manufactured in two colors, bluish gray and tile red. The last of these products is an asphaltic paint which may be applied to building stone for protection against dampness and staining. The booklet will be found invaluable to contractors and builders often experiencing trouble from dampness, and a copy may be had free on application to the company at the given address.

The Ideal Mortar for Brick Masonry

Under the above title there has just been issued by the Hydrated Lime Bureau of the National Lime Manufacturers Association, Arrott Building, Pittsburgh, Pa., what is known as Bulletin J, bearing date of June 1, and giving the results of an investigation conducted by Prof. James S. Macgregor of Columbia University, showing the practical effect of hydrated lime on the strength of cement mortars subjected to the normal

effected a considerable saving in time by using a mixer with a drum capacity considerably larger than the regular batch. With this additional drum capacity it was not necessary to discharge all of one batch before the aggregates for another were inserted, and the work therefore proceeded without interruption. The contractors give as the three main features in the economy of operating their mixing plant the great portability of the mixer, enabling it to be readily moved to any required position on the job, the low charging features requiring few workmen, and the reserve drum capacity insuring least delays in operation.

The Pormo Portable Pumping Unit

An outfit for use in pumping out excavations and foundations which embodies features likely to interest the contractor, is the Pormo portable pumping unit made by the Aerothrust Engine Company, 328 Washington Street, Laporte, Ind. The point is made that the outfit is hand-portable because two men can easily carry it directly to the job. It is said to be so constructed that it can be put at work anywhere and the speed instantly changed while in use, thus offering a wide range in capacity. It has a high-tension waterproof built-in magneto. It is equipped with a Pormo

USA WHITE CEMENT

Residence of John C. Reid, Wheeling, W. Va. C. W. Bates, Architect. Wm. C. Baughman, Plastering Contractor. Exterior Plaster Finish of Medusa White Portland Cement.

Up-to-Date Houses Are White Houses

Architects are designing white concrete and stucco houses today as never before. Leading magazines are showing pictures of the artistic effects to be obtained with White Portland Cement. Leading contractors are building those houses by using

MEDUSA

Waterproofed

White Portland Cement

the only Waterproofed White Portland Cement manufactured. It is the ideal medium for exterior construction. Stands up in all sorts of weather. Takes color perfectly. Houses made with Medusa Waterproofed White Cement are durable, fire-proof, sanitary. It gives a house a character and distinctiveness which stand as a permanent advertisement for the builder. It saves you money because the water-proofing is already mixed at our factory—at a lower cost than you could mix it yourself.

People want white houses. Make sure that you do a good job by using Medusa—the first true White Portland Cement—or Medusa Waterproofed White Portland Cement—the only Waterproofed White you can buy.

Write today for booklet on Medusa Waterproofed White. It will help you on your next job.

KOHLER

The factory,
the product, and the
trade-mark

Kohler, Wisconsin, where
KOHLER WARE is made, is a
community which is devoted
solely to this industry.

It has no divided interests. Its single
activity is the production of enameled
plumbing ware of one quality—the
highest.

KOHLER WARE

is notable for its beauty

Every KOHLER bathtub, lavatory
and sink is distinguished by the trade-
mark KOHLER permanently incor-
porated in faint blue in the enamel.

This trade-mark is our guarantee of
KOHLER quality—always the highest.

KOHLER designs are modern and
hygienic. The enamel on KOHLER
WARE is beautifully white.

Write for a free copy of our new book
"KOHLER of KOHLER", which con-
tains a full description of the "Viceroy"
one-piece bath, the most popular built-
in tub ever constructed. Specially low
price due to manufacturing economies.

engine with Gould centrifugal pump and has a capacity of 125 gal. per minute. The company has issued a catalogue setting forth the advantages of this pumping unit and a copy of it can be obtained by any building-contractor who may make application for it.

The "Davy" Gas Heater for Small Garages

During the winter months, the owner of the small garage desires a supply of heat in order to render the place comfortable, but it is seldom that he can satisfactorily accomplish this from his house heating system. He is therefore likely to be interested in the "Davy" Gas Heater which has been placed upon the market as a solution of the problem of heating small garages. The heater is constructed entirely of sheet metal having a galvanized crimped metal casing which is open at the bottom and covered with perforated metal at the top. Inside the casing and 2 in. away from all sides is a galvanized metal combustion chamber at the bottom of which in one corner is an intake. Above this and on the inside, is the burner. The yellow flame giving off its heat together with the hot gases of combustion are made to travel up to the top by means of a U-shaped deflector. In this way the heated air circulates and comes in contact with the entire surface of the combustion chamber which becomes the radiator. At the lower corner of one side of this radiator is a vent which permits the spent products of combustion

Fig. 4—View Looking Into a Small Garage and Showing the "Davy" Gas Heater in Place

to escape. The whole outfit is self-contained and supported on iron pipe standards. Ordinarily a $\frac{3}{4}$ in. gas connection is required, but a thermostat as shown in the picture, Fig. 4, which represents the gas heater installed in a garage, may also be used for economy in gas consumption. The claim is made that in the case of garages of the smaller type, any gasoline vapor that may be in the air would combine with the supply and enter the burner through the intake and be consumed in the heater without any danger. The device is being placed upon the market by Kidde & Co., 90 West Broadway, New York City, and the construction has been approved by the New York City and other fire departments as a safe appliance to use in heating garages and other places where volatile and explosive vapors may collect, as in varnishing and cleaning rooms. It has also been approved by Boards of Health for use in moving picture theatres and in the home, as it is said it will not contaminate the air. The heater is offered in two sizes, one of which is intended for a garage measuring 16 x 20 ft. in plan and the other for a structure 20 x 26 ft. in plan.

Reeves Sheets and Sheet Metal Products

A Beautiful Book Free

The 1916-17 edition of "Repairing and Building" is now ready.

It is beautifully lithographed and has many illustrations in colors, and in black and white. It shows exteriors and interiors of all kinds of buildings. Its object is to demonstrate to carpenters and builders the many attractive features of

NEPONSET Shingles and Wall Board and other Neponset Products

which are fully illustrated and described.
Will you write for your copy today? It is absolutely Free, and your sending for it does not imply the slightest obligation. Use the coupon below.

An Unnecessary Accident—

On the garages you build, whether they are simple or elaborate, you will find it wise to use Stanley Garage Hardware and the

STANLEY GARAGE DOOR HOLDER

The Holder is strong and simple in construction, holds the door open against the heaviest gusts of wind, preventing damage to car lamps, bending of the fender or scratching of paint.

Our book "E" on Stanley Garage Hardware is really interesting, and contains much data of value to architects, carpenters and builders. May we send it to you?

73 East Lake St.
Chicago

publication sent out by The Reeves Manufacturing Co., Dover, Ohio. The work is profusely illustrated, attractively printed, bound in paper covers and gives evidence of great care in its preparation. The early pages are given up to a bird's-eye view of the company's plant at Canal Dover, also views of the shipping facilities. The shipping department is located in the center of the company's large warehouse, which lies parallel to the railroad tracks, and is served by both the Pennsylvania and Baltimore & Ohio railroads. The goods shown cover a very extensive variety, including practically everything in the sheet metal line likely to interest the architect, the builder, and the sheet metal contractor. Valuable tables are presented, giving sizes, weights and gages of sheets, also net prices of gutter per 100 ft. at various discounts—a feature which many in the trade will appreciate. The catalog is divided into sections, the first of which embraces roofing, another deals with eaves trough and conductor pipe, another with Reeves' metal tile so made as to represent most faithful imitations of clay tile; another section has to do with tin plate, and another with stove pipe and elbows. Probably the most attractive section is that relating to Reeves' artistic metal ceilings. In this section are shown a few of the large number of ceiling designs turned out by the Company, and showing most clearly the deep, rich embossing. The concluding sections are given up to charcoal iron and to various items of information likely to prove of interest and value to the trade. Included in the latter are suggestions as to weather conditions, the wind pressure on roofs, weights of roofing materials, general mathematical rules, temperatures, etc., etc. The catalog concludes with a comprehensive index alphabetically arranged. We understand that a copy of this handsome catalog will be sent to any reader of THE BUILDING AGE who may make application for it.

Irwin Improved Bit Shank

Announcement has recently been made by the Irwin Auger Bit Company, Wilmington, Ohio, that the shanks on Irwin bits will hereafter be made by an entirely new process. A patented measuring device has been per-

Fig. 5—View Showing How the Irwin Improved Shank Holds the Bit in Correct Alignment

fectured for attachment to the dies with which the shanks are made and because of the fact that the dies permit little or no variation all the shanks of the Irwin auger bits are now said to conform to one standard. Heretofore they were made by a hammering process, and the squaring of the shank was left entirely to the eye of the operator. The new process eliminates guess work. The corners of the four sides of this new shank fit into the

Fiberlic

for Walls and Ceilings

FIBERLIC WALL BOARD—
A root fibre product. A chemically cleaned, tenacious fibre made into board. Solves the requirements of wall board construction. Not an experiment. We have never changed our brand. Fiberlic Wall Board means one standard only. It was made right first.

NOTE: All our samples are cut from stock and truly represent what we ship.

FIBERLIC DEPARTMENT
MAC ANDREWS & FORBES COMPANY
CAMDEN, NEW JERSEY

NEW and distinctive markings have been adopted for the sides of all packages of Dutch Boy white lead. Instant identification of this reliable paint material is now easy.

Each black steel keg has the familiar figure of the Dutch Boy Painter and our guaranty on the side in brilliant orange. In addition, the words **DUTCH BOY WHITE LEAD**, in large legible type, appear between two bright orange stripes as shown in the illustration.

NATIONAL LEAD COMPANY

New York Boston Buffalo Chicago
Cincinnati Cleveland St. Louis San Francisco
Philadelphia (John T. Lewis & Bros. Co.)
Pittsburgh (National Lead & Oil Co.)

angles of the jaws of the brace chuck in such a way that the bit will be held always in correct alignment. This is accomplished by the sides of the shank being perfectly square. If there were even a slight variation in one or more sides the bit would be held at an angle and cause an imperfect cut. The company states that if a number of these new bits are placed with the sides of the shanks touching each other they will form a circle, thus proving the accuracy with which the shanks are made. In Fig. 5 is shown the manner in which the improved shank holds the bit in proper alignment.

The "Brackett" Hollow-Chisel Electric Mortiser

A mortising machine embodying features of construction which cannot fail to strongly appeal to the carpenter-contractor, the builder and, in fact, all operators of small wood-working shops, is illustrated in Fig. 6. It is known as the "Brackett" hollow-chisel electric

Fig. 6—General View of the "Brackett" Hollow Chisel Electric Mortiser

mortiser, and is so made, it is claimed, as to entirely overcome the objectionable feature of "split" chisels. The point is made that the bit will cut cypress, spruce, yellow pine, fir or other pithy wood, and do it quickly and cleanly, without injury to either bit or chisel. The special construction of the bit and the high speed at which it turns are the basis of the success of the machine. The arrangement of parts is such that the chips are cut as fine as saw-dust and are rapidly elevated through the chisel and discharged through two large openings, thus instantly relieving the bit from excess friction and eliminating the strain on the chisel. In other words, there is practically no chance to "choke" the chisel with chips. The picture here presented offers an excellent idea of the general appearance of the machine and arrangement of parts. It is being placed on the market by Warren W. Morse, of Hopkins, Minn.,

LEVER HANDLES

have an artistic value and an individuality which commend them to people of discriminating taste. They are especially desirable for doors with narrow stiles, French windows and cabinets, and can be used instead of knobs on any Corbin escutcheons. We illustrate a few selections from a large assortment. Full particulars on request.

P. & F. CORBIN

The American Hardware Corporation Successor
NEW BRITAIN, CONN.

The Wheel of a STERLING WHEELBARROW

and its

Pre-Lubricated Bearings

When all's said and done, the difference between a good wheelbarrow and a poor one is mainly in the wheel and its bearings.

In making the Sterling Wheel we first upset the shouldered Steel spokes into the heavy steel rim, as shown in Fig. 1.

Then the long sleeved steel hub is set into a special shaped mold, and molten iron is poured into the mold, cementing spokes and hub into one solid piece, as shown below in Fig. 4.

The Steel Sleeve of the hub is fitted with pre-lubricated fiber bushings, as shown in Fig. 2.

These bushings are filled with a composition of oils which thoroughly penetrate the pores. The bushings are then driven into the hub under great pressure. The longer the cold drawn steel axle turns in these bushings the smoother they become, and they never require oiling.

This bushed hub revolves round the axle. Note that it fits into recesses in the end-brackets (see Fig. 3). This construction affords valuable protection against sand and dirt.

The axle is cold drawn steel. See how it is keyed to the end-brackets with cotter pins, and how the malleable brackets themselves are secured to the bottom of the nose-end of the handles. There are no nuts to work loose; no side play; nothing to get the "ricketts."

This is a real wheel, friends; built to last; a wheel that ensures light, noiseless traveling under the heaviest loads.

There are a lot of other exclusive features about the Sterling Wheelbarrow, but its wheel alone is enough to make the discriminating buyer give it a very decided preference.

Send for our
Catalog No. 24

Sterling Wheelbarrow Company

6201 Shenners Avenue

who states that the machine is sold strictly on its merits and that if not as represented it may be returned, and the money will be refunded or the builder can make arrangements to test out the machine in his own shop before paying for it.

The "Alamo" Schoolroom Heater

Building contractors and architect-builders who are often called upon to recommend an efficient heating equipment suitable for schoolrooms are likely to find many points of interest in the apparatus manufactured by the Alamo Heater Company, 70 West Lake Street, Chicago, Ill. In the first place it is important to mention that the heater is provided with a humidifying device which insures the pupils getting an atmosphere containing a healthy and comfortable percentage of moisture. The "Alamo" heater is gas proof because it is jointless, being made from wrought steel which is welded into one piece by an acetylene process. This body is 22-in. diameter, and is surrounded by a 34-in. casing. With all castings set back this far from the casings it removes all danger of the pupils burning themselves. The equipment is 60-in. high. The firepot is 20-in. dia., and a generous grate surface 17-in. dia. is provided. It is suggested that the heater be

Fig. 7—Broken View of the "Alamo" Schoolroom Heater Showing Internal Construction

installed on a cement base so that all danger of fire may be avoided. Foot warmers can also be placed on either side of the heater, the doors and slides for which are made of wrought steel. A continual supply of pure, fresh air is assured by an outside duct which should make connection with the heater either above or below the floor. A small fire in the heater makes a positive upward current of foul air which is conducted through the roof by means of a concealed duct. Each equipment is furnished with the humidifier, three lengths of 7-in. planished iron smoke pipe, one 7-in. adjustable elbow, and one smoke collar. Additional material can be had according to requirements. A view of the heater is shown in Fig. 7.

Municipal Swimming Pool in Toledo

One of the popular objections to concrete by those not altogether familiar with the material is that it is often subject to percolation, discoloration, efflorescence and other defects due to the action of water. An interesting example of the value of a waterproofing compound in obviating these objections is to be found in the present excellent condition of an open-air swim-

ming pool built three years ago in City Park, Toledo, Ohio, in connection with which Medusa Waterproofing was used. A half-tone engraving of the pool and interesting information relating to Medusa Waterproofing is contained in a four-page folder being sent out by the Sandusky Cement Co., 624 Engineers Building, Cleveland, Ohio. The swimming pool is 60 x 180 ft. and from 1 to 4 ft. deep, contains two basins and is surrounded by a walk 12 ft. wide. It is said that no leaks have developed, which is a good testimonial from "Time" as to the merits of this waterproofing.

The Blue Book of Traffic

A brochure of decided value to the builder or contractor interested in motor trucks is "The Blue Book of Traffic," handsomely printed on coated stock, with an attractive blue border running around the pages. There are 102 half-tone engravings, featuring motor trucks used in over fifty different lines of business and, as the engravings are two to a page, they are of sufficient size to enable a prospective purchaser to obtain a good idea of this line. Considerable space is also devoted to a description of the various units and construction of these trucks, together with condensed specifications, accompanied by a side view and also a view from underneath the chassis of each style. Photographs of worm drive trucks only are reproduced, for the reason that the Federal Motor Truck Co., Detroit, Mich., who issues this brochure, are now only manufacturing this style of drive. Three photographic views show the first Federal plant and its growth to its present size. As the brochure is a comprehensive treatise on motor trucks, presented in such a manner as to make the subject one of interest to the ordinary layman, it cannot fail to prove instructive to every building contractor contemplating the use of a motor truck in his business.

Convention of Sargent & Co. Salesmen

The annual convention of the salesmen of Sargent & Co., New Haven, Conn., was held at the factory during the week beginning June 26, and was attended by members of the selling force from all parts of the country and one representative from Australia.

The sessions were held in the convention hall, which was appropriately decorated with the national colors and contained a complete display of the advertising material issued by the company, also many samples of the new goods which have been made since the meeting of last year. Two sessions were held daily, the entire time being devoted to the consideration of business conditions and methods of marketing the product of the company. These sessions were presided over by Henry B. Sargent, who opened the convention with a few words of welcome and closed it on the last day with an inspiring address.

On Tuesday evening, June 27, the banquet of the salesmen and factory heads of departments, which is a feature of the annual convention, was held at the Shoreham Hotel, about 150 being present. The company was placed at small tables so arranged that the factory men and those from out of town were seated in alternation, giving them all an opportunity to renew acquaintances and exchange experiences. At each place was a souvenir paper cutter made at the factory, representing a front door escutcheon and knob in an ornamental design and bearing the company trademark and the date.

Addresses were made by Henry B. Sargent, vice-president and general manager; Joseph H. Cherry, manager of the export department; John H. Shaw, factory superintendent, and F. W. Robbins, of the New York office.

The "Highwood" Dumbwaiter

The Highwood Dumbwaiter Company, 134 Highwood Avenue, Leonia, N. J., calls attention to the fact that its "Highwood" dumbwaiter is furnished ready to erect and can be easily installed by any carpenter or builder.

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as he expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

10 East 43d St.

Pittsburgh Office,
Liberty Bank Bldg.

Stanley Improved Leveling Stands

A Stanley Level Stand used in connection with a wood or iron level, and a pair of level sights will be found in many cases a very satisfactory and inexpensive substitute for the more expensive surveyors' instruments.

By its use one can readily determine levels from a given point to one at a distance, such as locating or setting the profiles for foundation work, ascertaining the proper grades for drains, ditches, etc.

It can be placed on a stake or crow-bar and adjusted to a horizontal position even though the stake or crow-bar may not be exactly perpendicular.

A thoroughly practical tool.

Price of Stand with a 12-inch metal level and a pair of level sights—\$4.50.

Price of Stand only—adapted for either wood or metal level—\$2.00.

Send for special circular.

STANLEY RULE & LEVEL CO.
NEW BRITAIN, CONN. U.S.A.

The price at which the company is offering this dumbwaiter, announced elsewhere in this issue, includes a 24-in. square car, machine set on timbers, counterweight, ropes, nails, etc.; in fact, everything that is required to render the apparatus complete. The point is made that it is of substantial construction, practical design and easy operating. A strong point which the company makes is that satisfaction is guaranteed or the money will be refunded. A catalog which has been issued illustrating and describing the dumbwaiter can be had by making application to the address given above.

Arkansas Soft Pine in Building Construction

There are houses scattered throughout the country which were built long before the Revolution, and are to-day in an excellent state of preservation, ordinary care having made them endure through the centuries, so that there is no reason to doubt the durability of wood. Among the woods of quality Arkansas soft pine lays claim to a prominent place, as it was used in houses erected sixty or sixty-five years ago and which are still in a habitable condition, even though few of them have received proper care. Yellow pine, of which general species Arkansas soft pine is an aristocratic member, came into general use in sections other than its native state about twenty-five years ago. A now rapidly disappearing prejudice was at first felt against all yellow pine owing to the relationship with so-called Georgia or pitch pine, but it is claimed that Arkansas soft pine possesses none of these objectionable qualities. The latter wood is light, tough of fiber and has a soft, lustrous, satin-like texture, being therefore adapted to interior woodwork of all sorts. The beauty and wide variety of grain is said to make the wood useful for imitation of oak, mahogany and similar effects, while it also serves as an excellent basis for white enamel finishing, as it will permit of a mirror-like smoothness and will not discolor the finish from underneath. Arkansas soft pine is supplied in various lengths, including 12 ft., 16 ft. and 20 ft., so that in many cases a floor may be laid of single board lengths, thus minimizing the number of end joints. All of these facts, as well as other interesting information regarding this wood, are to be found in a handsome brochure, entitled, "Not a House but a Home," which is being sent out by the Arkansas Soft Pine Bureau, Little Rock, Ark. The advantages of Arkansas Soft Pine are set forth in connection with its use in framing and interior finish, including instructions for waxing, varnishing, etc. Features of foundation work, plaster, etc., are briefly discussed, and among the many illustrations is a panel showing the different grains of the wood. Instructive material relative to finishes like dull varnish, silver grey, enamel, gloss varnish, natural finish, etc., together with general directions for their application, are also set forth. A valuable feature of the handsome work is a series of six designs of houses, including plans, elevations and details, with the cost of different classes of work in connection with each design. The houses shown range in cost from \$1,200 to \$12,000, and have been specially designed along Colonial lines for the brochure by Aymar Embury II, a well-known New York architect. These houses, the architect states, were designed primarily with the intention of obtaining as large a percentage of the area of each house in usable rooms as possible. In regard to the exterior, the architect says: "There was one point which was borne constantly in mind, and that was that the apparent height of the buildings must be reduced as far as possible. The greatest difficulty with most of the carpenter-built houses of to-day is that they are too high for their length and breadth, and the long, low effect so charming in old work is absent from them. The height of a building is a relative matter. A cornice 17 ft. from the ground in a building 70 ft. long, gives the effect of a long, low house, but a cornice 17 ft. from the ground in a building 21 ft. long will give it almost the appearance of a tower, and the cornice heights of all the houses therefore have been considered with relation to their lengths and breadths." He states he has endeavored in the design of these exteriors "to avoid the most common of all faults—the introduction of too

many motifs in a small space. The very large house can stand a variation of façade by the introduction of gables, bays or other similar features, but the small house must exhibit in its façade a single idea, carefully thought out, and must depend for its effect upon the just proportion of its height, length and breadth, together with perfection of detail." Care has been taken to render the heating and plumbing economical, one chimney sufficing for kitchen range and living room fireplace, and the bathroom has been placed over the plumbing on the first story.

Modern Plumbing

The architect, the builder and the house owner are interested in modern plumbing equipment, and they are therefore likely to find much to command their attention in the handsome catalog of 138 pages which has just been issued under the above title by the J. L. Mott Iron Works, Fifth Ave. and 17th St., New York City. It is known as "No. 10" and contains a vast amount of information relating to up-to-date plumbing fixtures, accompanied by well executed half-tone engravings, showing bathroom interiors with the fixtures installed. Among noticeable features of the catalog are lavatories with iron brackets and shields, thus eliminating pedestals, legs or metal brackets which are difficult to keep clean; toilet tables with iron brackets and vitreous china shields; siphon-jet water-closets with cabinet finish quartered oak or birch-stained mahogany chairs with push-button flush valve concealed in the floor, and bath tubs with rain shower having adjustable ball joint and arm attached to the wall, also anti-scalding valve concealed in the wall, concealed waste, etc. The idea of the catalog is to show a large variety of well-designed fixtures, thus making it possible for the taste and individuality of the architect and owner to be reflected in the character of the fixtures chosen. In connection with the various fixtures shown are brief descriptive particulars, dimensions and prices, all ar-

ranged in a way to prove of the greatest advantage. In addition to bathroom fixtures, attention is given to kitchen sinks and laundry tubs. Especially interesting is a floor plan of a kitchen with a butler's pantry and laundry showing the proper position of each of the various fixtures constituting the equipment. There is also a picture showing some of the salient features of a well-appointed modern kitchen.

New Factory for Sasgen Derrick Co.

Among recent expansions along industrial lines in Chicago, Ill., a notable instance is seen in the case of the Sasgen Derrick Co., which for several years has operated a plant at 2053 North Racine Avenue, and is now confronted by a situation which makes greater facilities and equipment imperative. A new plant, 57 x 207 ft., is in course of construction at the corner of Grand Avenue and Albany, and the site will have the advantage of railroad facilities from the Chicago, Milwaukee & St. Paul line. The factory will be a one and two-story building, and of mill construction. Besides adding considerable to the factory quarters the new plant will house commodious offices and a garage. The first floor of the two-story section will contain the machine shop and stock rooms, while the second story will house the offices and salesrooms. The entire one-story section will be devoted exclusively to a carpenter shop. The factory throughout will be operated on a modern efficiency basis and its capacity will be increased about 200 per cent by these improvements. The company will therefore be enabled to handle its increasing business for builders' derricks with every guarantee of prompt service and general satisfaction.

Soller's Self-Calculating Scale for Stair Builders

We have received from Russell C. Smyers, 17 West Water Street, Mount Union, Pa., a copy of a self-

(Continued on page 92)

Put This in Your Kit

Here's a tool no carpenter can afford to be without to meet the unusual boring situations that come up.

MILLERS FALLS EXTENSION BIT HOLDER No. 6

Chuck follows into a $\frac{5}{8}$ -inch hole yet holds bit with an immovable grip.

Jaws of one piece of the toughest steel.

Outer sleeve telescopes over inner spindle, combining lightness and strength.

Takes up little room in the kit—extended easily in a second—Collapsed $16\frac{1}{2}$ inches, extended 24 inches.

Mechanic's Handbook—full of valuable information never compiled before—free on request. Send for Pocket Catalog.

Something New!

This new convertible level is a big improvement over the old style instrument with detachable standards. Can be converted into transit while you count ten. Not only saves time but cuts out confusing adjustments. Most compact, durable and accurate convertible level on market today. Write now for detailed description, price, etc., and get posted on this up-to-date instrument for up-to-date contractors.

DAVID WHITE CO., (Inc.) 421 E. Water St. MILWAUKEE, WIS.

Pullman ALL STEEL Unit Sash Balances Noiseless

Is the word that describes the operation of the Pullman Unit Sash Balance. All parts are in the casing—nothing can rub or interfere with the spring action. There is nothing to squeak, rattle, bang or stick. Once installed and it will never require contractors', builders' or architects' attention. There is in every Pullman Sash Balance satisfaction for owner and builder alike. Guaranteed for 10 years.

Our catalog with blue print gives full particulars. May we send one?

Valuable Tables for finding size of joist, safe load of joist, actual load on hanger, etc., etc.

Some of these Tables are not in print elsewhere.

The Pamphlet and the Mounted Model Hanger will be mailed on request.

SOMETHING FOR US. We ask your special attention to items 5, 6, 7 on page 5 of the Pamphlet and to the matter on pages 23 and 24 relating thereto.

THE W. J. CLARK CO., Salem, Ohio, U. S. A.

calculating scale for stair builders, which he is offering to the trade at a price of \$1.00. The work consists of a series of tables which divide any height for stairs beginning at 2 ft. into the indicated number of equal spaces and is carried by increases of single inches to 16 ft. The divisions are given in inches and hundredths of inches. The calculator also divides treads as well as rises, and the tables may be doubled or increased any number of times to divide any space desired.

New Line of Heppes Asphalt Shingles

In order to meet the demand for an asphalt shingle of the same quality as its diamond point slab, but different in shape and appearance, the Heppes Company, Dept. G-1011 Kilbourne Avenue, Chicago, Ill., has brought out what is known as Style 4 Square Butt Slab. Like the diamond slab, this new style is really 4 shingles in one, and a considerable saving of time over the old way of laying single shingles is said to be effected. No time is wasted in chalk-lining because the slabs automatically space and gage themselves. They give the appearance of single rectangular asphalt shingles with the economy of the slab.

TRADE NOTES

"The Roof of Eternal Youth" is the title of an attractive catalog sent out by the F. C. Sheldon Slate Co., Granville, N. Y., and within its covers interesting comments are presented regarding the product of the company. These slates are mined in a variety of natural colors, sizes and thicknesses, and are said to harmonize closely with any individual color scheme it is desired to employ. Several pages are devoted to photographic reproductions of slates showing approximately their natural colors.

W. H. Bennett, for over two years with the Marsh-Capron Mfg. Co., Chicago, Ill., has accepted a position with the Searchlight Co. as advertising manager.

The T. L. Smith Co., 3120-H Hadley Street, Milwaukee, Wis., announces that its district manager, E. R. Marker, has removed to 609 Wells Street, Milwaukee, where he will act as Wisconsin representative, carrying a stock of mixers on the floor and a complete line of contractor's supplies.

The honor of being the first fire department in the state of Connecticut to motorize is claimed by that in the city of Middletown, which has recently purchased another Federal tractor to be used with the hook and ladder. This little item is found in *Traffic News*, the house organ of the Federal Motor Truck Co., Detroit, Mich. There is also much other information bearing upon the motor trucks of this concern which cannot fail to prove interesting to building contractors who are thinking of substituting vehicles of this nature for horse teams.

When making corrections or notes on blueprints it is usual to employ a red pencil, but this combination of red or blue is apt to prove trying to the eyes. A white pencil is by many thought preferable and Dixon's best white pencil No. 352 is intended for this purpose, says the July issue of *Graphite*, the house organ of the Joseph Dixon Crucible Co., Jersey City, N. J. To the owner of an automobile it is interesting to note that all those who finished in the Sixth Annual Indianapolis Sweepstakes Motor Derby used Dixon's graphite automobile lubricants. Other items of information along similar lines are contained in the July issue.

The L. & I. J. White Company, Buffalo, N. Y., is directing special attention to its flooring pattern of hand axe. The tool is made with the end perfectly straight and at right angles with the handle, so that either in pounding or cutting the handle clears itself from the floor, which does away with a lot of bruised knuckles on the part of the workman and poorly finished jobs. The company expresses a preference for the mechanic to give his orders through his local dealer,

(Continued on page 94)

Summer Is Building Time

Soon there will be a demand in all localities for men to build new barns.

This call is welcomed by the contractor who uses **PORTER SERVICE**, since he knows he can build the new barn in double-quick time and guarantee a thoroughly modern and workmanlike job.

Consider what it means to receive authentic and practical data covering the construction, arrangement, ventilation, etc., of each individual barn. That's what **PORTER SERVICE** renders—and it's **FREE**.

MYERS HYDRO - PNEUMATIC PUMPS BRING CITY WATER CONVENIENCES TO ALL

A Myers Hydro-Pneumatic Water System is inexpensive and it will give first class service. Both air and water are pumped into the supply tank. The air, after it has become compressed in the top of the tank, drives the water through the service lines. It is not necessary to have an elevated tank and installation is easy. Pumps are made for operation by hand, gasoline engine or other power.

Write to our Service Dept. for catalog and information.

F. E. MYERS & BRO., Ashland, Ohio
ASHLAND PUMP AND HAY TOOL WORKS

but in case the dealer will not order for him or tries to furnish something "just as good," the company will be glad to receive the order direct.

In the review of the little work entitled "A Book About Slate," which appeared in our July issue, it should have been stated that the booklet is the property of the J. E. Bray Slate Co., East Bangor, Pa., and is primarily issued for the purposes of furthering the interests of this concern, which succeeds the firm of J. Bray & Co. Arrangements are being made for an increased business this fall with improved facilities.

Those employees of the Joseph Dixon Crucible Co. who had joined the National Guard prior to its being called by the President and subsequently sworn into the Federal Service in June, 1916, will receive full pay while away doing military duty. These men will have their places kept open for them. This provision holds good until future developments make it necessary to change or modify it.

William A. Gill, formerly vice-president of the Kinnear & Gager Manufacturing Company, Columbus, Ohio, has succeeded the late Edwin B. Gager as president and treasurer of the company. John M. Gleason, manager of the Boston office, will be vice-president and general manager, while A. D. Bierman will continue as secretary and George W. Harlam as assistant treasurer.

On the 1st of July the corporate name of the Caldwell Auger Bit Company, Lebanon, N. H., was changed to the Lebanon Machine Company, which in the future will manufacture the Lebanon high-speed "Z" twist auger bit and other high-grade wood-boring tools.

In connection with the "Carter Paint Calculator," briefly reviewed in the issue of THE BUILDING AGE for July, the statement should have been made that the little work will be sent without cost to building contractors, architects and painters who may be sufficiently interested to make application for it. The company states that any reader of THE BUILDING AGE who sends an order for the Calculator will receive it with its compliments.

Have You Made The Mistake

of thinking that Compo-Board is the name of *any* composition wall board?
Have you overlooked the fact that the *genuine*

is made with a center core of kiln-dried wood slats—is the only wall board so made—and as a result of this unique patented construction possesses a strength, durability, cold, heat and moisture-resisting quality, decorative adaptability and other features that make it far more satisfactory than lath and plaster or other wall boards?
Do you know also that it *does not have to be paneled*, because it saws with such smooth edges, and is so stiff it can be papered? Thus two of the greatest objections to giving up the traditional lath and plaster are overcome.
If you would be *modern* in your ideas about building, you owe it to yourself to get acquainted with Compo-Board. Write for free sample and interesting book.

The Compo-Board Company

GARAGE EQUIPPED WITH SIX DOOR OUTFIT, OPENING 18 FEET WIDE
DR. J. W. DRYER, OWNER; JOHN ARMERUSTER, CONTRACTOR

Designed to meet the demand for a fixture that will allow hinge doors to fold and swing inside of building requiring only minimum space.
This fixture is not recommended for doors over 3 feet wide.

No. 435 R-W Sliding-Folding Garage Door Outfits

Four doors hinged together in pairs are required for each opening, one pair folding to the right and the other to the left. When needed, however, five or six doors can be used, in which case the center doors swing free, making ideal entrance doors. Will stand at any angle depending, however, upon the width of the wall space adjoining the opening. Where wall space is greater than width of doors, same can be made to fold back when open, parallel with the front walls. Blue print showing erection details furnished with each order.

Architecture, Carpentry and Building
consists of ten large volumes, handsomely bound in half morocco, gold stamped, containing 4,760 7 x 10-inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross indexed for quick, easy reference.

PARTIAL TABLE OF CONTENTS
Mechanical, Freehand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

Plan Book and Consulting Service FREE
We give free to every purchaser of our Cyclopedia of Architecture, Carpentry and Building, a copy of "Modern American Homes," a complete and up-to-date plan book. Contains plans and specifications for 168 structures, including excellent exterior and interior views, detailed estimates, etc. Designed by leading architects, it covers city, suburban, and country homes; bungalows; summer cottages; tent houses and camps; apartment houses; garages, and public buildings. 234 pages, 9 1/4 x 12 1/4 inches, and 426 illustrations. Printed on enameled paper and substantially bound. With this plan book in your shop you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect—you can offer him his choice of practically every type of home. This saving of the usual architect's fee should get you the business.
In addition we give free with each set a year's consulting membership in the American Technical Society. Through this service you have the assistance of a staff of architectural and building experts. These men are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

Send for this great combination today
We will send the complete eleven volumes to your home for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet your expectations they may be returned at our expense. If you keep them send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80—regular price \$50.00—has been paid. Remember—the consulting membership and plan book are included absolutely free.
Can you afford to let \$2.00 a month—50c a week—stand between you and success? The consulting membership alone is worth many times the first cost of the books. Fill in and mail the coupon—NOW!

American Technical Society, Chicago, U. S. A.

As I have had no previous dealings with you, I refer you to

Grimm's Galvanized Corrugated Wire Lathing

requires no furring on account of the V-shaped corrugations which are imbedded at intervals of seven inches.

This feature alone is worth considering but that's not all. It WILL NOT RUST as it is heavily galvanized with the finest grade of Western Spelter and is much easier to handle and will conform to irregular curves much better than any other form of metal or wood lath.

Walls or ceilings plastered on this lathing WILL NOT CRACK OR DROP OFF, owing to its great keying qualities, which we will explain if you will drop us a card asking for our booklet No. 61 and samples.

We also manufacture Greening's Patent Trussed Steel Wire Lathing, "Buffalo" Crimped Wire Concrete Reinforcing, "Buffalo" Wire Cloth of all kinds and Wire and Artistic Metal Work for all purposes. DROP US A LINE AT ONCE and ask for Catalog 8-H.

BUFFALO WIRE WORKS CO.

(Formerly Scheeler's Sons)

Branch Office and Warehouse, 9-11 South 7th St., Philadelphia, Pa.

THE "FORSTNER" LABOR SAVING AUGER BIT BORES ANY ARC OF A CIRCLE

As it is guided by its circular rim instead of its center, and can be guided in any direction.

BRACE BIT

MACHINE BIT

Unequalled for fine carpenter, cabinet and pattern work. Specially adapted for hard wood working and against difficult grain and knots. Special prices in full sets.

THE PROGRESSIVE MFG. CO., Torrington, Conn.

Pearson's Automatic Shingle Nailer

Works well on any pitch roof. Gloves or mittens can be worn and nails driven faster than by the old way. This "Hand Nailer" is the only nailer. Throw nails in by the handful and start nailing, etc. Nails can be driven through tin or quite heavy sheet iron.

PAYS ITS COST ON ONE JOB

Two sizes: BLUE Nailer for 3d common No. 14 gauge wire nails. RED Nailer for 3d galvanized No. 13 gauge 1 1/4 inch wire nails. List price \$7.00 (but an order from this ad will bring you either size by prepaid parcel post for only Five Dollars).

-a different heater proposition

Even builders, contractors and architects are sometimes at sea when it comes to recommending or specifying a heater.

The many extravagant claims that are made by most heating companies don't give a contractor any sound basis for a recommendation—or to combat "come-backs."

The Williamson *New-Feed* UNDERFEED has changed all this—it is a proposition that is good all through. You can actually *guarantee* a customer that if he will install the UNDERFEED, it will cut his coal bills $\frac{1}{2}$ to $\frac{2}{3}$.

We back you. A million dollar corporation is behind your guarantee. Now that's pretty plain, isn't it? You can easily see how that guarantee boosts you.

-and the heater

The UNDERFEED is heating over 35,000 American homes and buildings at a coal saving of from $\frac{1}{4}$ to $\frac{3}{4}$. And here is the reason:

In an UNDERFEED, the fire is *above* the fuel, not smothered by it. This simple principle means no smoke, gas, dust, smell or clinkers, no matter if warm air, steam, hot water or vapor is used.

The coupon below brings special data of interest to you. Sign it and mail today. Don't delay—find out how you can guarantee to cut your customers' coal costs.

THE WILLIAMSON HEATER COMPANY
732 Fifth Ave., Cincinnati, O.

This Coupon Brings the Facts!

THE WILLIAMSON HEATER COMPANY,
732 Fifth Ave., Cincinnati, O.

I would like to know how to cut customers' coal bills from $\frac{1}{4}$ to $\frac{3}{4}$ with a Williamson *New-Feed* UNDERFEED.

How Close Do Your Estimates Run? Five Books to Help You

The stress of modern competitive bidding for construction contracts has caused the passing of the old-time guess-work estimate. Now-a-days, the Contractor and Builder, the Architect and the Engineer, Insurance Adjusters and Appraisers need a more practical basis on which to calculate costs or prepare estimates.

"THE NEW BUILDING ESTIMATOR," by William Arthur, is the modern working guide for all who figure the cost of building construction either in detail or approximately. It gives the actual time, labor, and material required on every operation in all classes of residential and municipal work. No expense has been spared to make the new edition complete and absolutely correct. "THE NEW BUILDING ESTIMATOR," with 248 added pages, thoroughly revised and reset throughout, now contains 744 pages, 5 x 7 inches in size, bound in flexible leather. It is the one indispensable aid in estimating. Owners of the older editions will surely want the new one. Price \$3.00 Prepaid.

"ESTIMATING THE COST OF BUILDINGS," by Arthur W. Joslin, a thorough and clearly presented system for figuring the actual cost of residential work, schools, banks, hospitals and other public buildings of moderate size, with chapters on reading architects' drawings. Special attention is given to the cost of building alterations. 238 pages; illustrated. Cloth Bound, \$1.50.

"ESTIMATING FRAME AND BRICK HOUSES, BARN, STABLES AND OUTBUILDINGS," by F. T. Hodgson, Revised 1913; 252 Pages; 25 Illustrations. Cloth Bound, Price \$1.00.

"THE ESTIMATOR'S PRICE BOOK AND POCKET COMPANION," by I. P. Hicks, a complete and convenient guide to the prices of all kinds of building material. The 1914 edition contains 172 Pages and over 100 useful tables; Handy Pocket Size; \$1.00 Postpaid.

"HICK'S BUILDERS' GUIDE," comprising an easy, practical system of estimating labor and materials. One of the most popular books; 23,000 sold. 166 Pages; 114 Illustrations. Cloth Bound, \$1.00.

The Hess Welded Steel Pipeless Furnace

Sales are made direct from factory to consumer, allowing two winter months of trial before we are paid. Our customers take no risk, but are insured against disappointment. Our booklets tell you all about furnace heating and about Hess Furnaces. Ask for them. Also send us a sketch showing your rooms to be heated and let us tell you what we can do, and the cost of the outfit.

We make special rates to contractors

HESS WARMING & VENTILATING CO.

1201 Tacoma Building, CHICAGO

White enameled steel medicine cabinets, also: Sanitary, handsome, cheaper than wood.

Warm Your Bungalow WITH A HESS Pipeless Furnace

No horizontal air pipes nor cold air ducts in this arrangement. One register only is used, a large one, which is placed in the main room. The warm air comes up through the center of this register and the cold air of the rooms is returned to the furnace through the ends, flowing down around the furnace and returning, warmed, to the rooms.

The circulation is rapid and complete, and warms all the rooms opening to the main room. It costs no more than a base-burner, takes less fuel and circulates the heat better than stoves, steam or hot water. Proper humidity is supplied by an ample evaporating pan.

Simplicity—efficiency—economy are the striking features of this heater and enthusiastic customers are proclaiming its great success.

Hess Welded Steel Furnaces

are made also in the usual form, with separate pipes and registers, suitable for all kinds of houses, churches, etc.

Every seam in the Hess Steel Furnace is riveted and then welded, making a seamless, one-piece radiator, which is absolutely and permanently proof against leakage.

The immense radiating surfaces distribute heat so rapidly that the heat from a couple of newspapers burned in the Hess Furnace is immediately felt at the registers, demonstrating economy and prompt response to regulation.

HEATING PLAN FREE

- ☐ Send us a rough plan of house you are building, and we'll submit heating plan and cost, without charge or obligation.
- ☐ The Amherst Furnace is a proven perfect heater, thousands in use, a heater that will help build or uphold a reputation for square, honest dealing on your part.
- ☐ The building season is fast approaching. So write at once, TODAY.

THE BEST ROOF

Building Construction and Superintendence

By FRANK E. KIDDER, C. E., Ph.D.
Architect

Part I.—MASON'S WORK, Ninth Edition

Thoroughly revised and enlarged by Thomas Nolan, Prof. Arch., University of Pennsylvania. A most exhaustive treatise on masonry construction for buildings in all its branches. New chapters on fire-proofing and concrete, plain and reinforced. Foundations have received careful consideration, and the most approved work in recent structures is clearly illustrated.

964 pages, 628 illustrations, cloth.

Price, \$6.00

Part II.—CARPENTER'S WORK, Ninth Edition

Treating on Wood Framing—sheathing, windows, outside door frames, interior woodwork, rough work, finish, heavy framing, builders' hardware, and the large variety of detail that the subject covers.

910 pages, 830 illustrations, cloth.

Price, \$6.00

Part III.—TRUSSED ROOFS and ROOF TRUSSES, Second Edition

This part describes nearly every type of roof construction commonly met with in buildings, pointing out the advantages of different types of wooden and steel trusses for different spans and building requirements. Special attention is given to description of wooden trusses and steel trusses, in order to make the work of practical value to the architect, draughtsman and builder.

294 pages, 306 illustrations, cloth.

Price, \$3.00

BAYONNE

Ten Years' Good Service!

For ten years now BAYONNE has been used by Architects wherever decks, verandas, sleeping porches, etc., requiring a covering of tested quality, a covering positively waterproof and wearproof—at the same time neat, attractive and economical.

BAYONNE

has been given preference by architects ever since its superior process of preparing was made known to them. This process renders it impervious to water—it never leaks; impervious to heat or cold—it does not shrink or expand, blister or crumble; impervious to the most constant use—it does not corrode.

And, in addition, it is the simplest and cheapest to lay.

Write for Sample Book "D" giving prices and laying instructions. See Sweet's, Page 426.

Give the House an Over-Coat of Stucco

and you have made a practically new house. But see that it has a lining of

SYKES Expanded Cup Metal Lath

SELF-FURRING

First, for the sake of durability.

Sykes Expanded Cup is the Metal Lath that gives the plaster or stucco a tight and everlasting grip.

Sykes Expanded Cup Metal Lath is heavier than others cut from the same gauge, being cut with a wider strand. This adds strength and durability. Sykes Lath is easy to apply and keys perfectly.

Second, for the sake of true economy.

No furring strips needed with this metal lath. This saves 5 cts. to 10 cts. a yard in building cost.

No furring strips needed with this metal lath. This saves 5 cts. to 10 cts. a yard in building cost.

For a good, strong metal lath; for a job that will give satisfaction—use Sykes Expanded Cup.

Best for Interior as Well as for Exterior Work.

Indorsed by U. S. Government for Post Office work. Approved by architects, builders and contractors. Write for Free Sample and Book of Specifications for Stucco on Metal Lath.

Sykes Metal Lath & Roofing Co., 494 River Road, Warren, Ohio

"The Lath with Suction"

C. M. L. BRICK LATH

Is What You Are Looking For

BECAUSE:

It has all the advantages of Expanded Metal Lath and moreover—

It bonds with plaster or mortar as quickly, easily and permanently as brick. In fact, it is a finely woven wire mesh covered with baked brick clay which forms a surface easy to plaster, and its construction eliminates excess loss of material by "drop" and "pushing through."

It is very flexible and economical to handle and has no sharp edges or points to cut or tear the hands—pliable and easily formed to curved surfaces or around right angles. It can be erected so as to prevent sagging and buckling, thus effecting a great saving of time and labor and insuring uniform satisfaction.

Write today before you forget it for samples and complete information.

WATERPROOF PLASTERGON TREATED WOOD FIBRE WALL-BOARD

(See how this 10-foot panel stands straight without bending. Send for actual photo.)

Comes Sized—

—Saving you \$4 to \$6 per M sq. ft. Waterproofed—sized—"lumberized," all in one process. Genuine wood fibre—nothing else. Nothing to hide or color over. Try Plastergon on some job where no other wall board will do. Our users say it has no equal at any price.

Your Safeguard in Buying No. 2

"I think Waterproof Plastergon is one of the best pieces of goods on the market today. The quality is good, the board is stiff when applied. . . . The price of Plastergon appeals to the trade."—W. J. Alexander, Steubenville, O.

Samples and our Contractors' Practical Working Guide sent free. Send the name of your Lumber or Builders' Supply Dealer. Write today.

Plastergon Wall Board Co.
2 Philadelphia Ave., Buffalo, N. Y.

Which is the Bad Egg?

We'll give you two guesses.*

With only the picture before you it's a *guess* at the best.

If you had the actual eggs in your hand, there would be two ways to find out which was the bad one.

You could hold them up to the light and tell.

Or you could bake each one into a cake and tell the bad egg by tasting the cake.

But why spoil the cake?

There are good wallboards and bad. You can't tell a poor piece of wallboard by its looks any more than you can a bad egg. Defects in wallboards only show up on the finished wall and then usually, they are glaring defects. You can't afford to spoil the room in order to test the wallboard. There is one way and only one way to be sure. There is only one standard and that standard is Beaver Board—the pioneer in its field.

Beaver Board gives you handsome, permanent, serviceable walls—better than lath, plaster, steel or wood.

But you can't expect Beaver Board results unless the Beaver trade-mark is on the back of the board you buy.

Write for booklet and sample.

THE BEAVER BOARD COMPANIES

Kidder's Architects' and Builders' Pocket Book

The 16th revised and enlarged edition of this standard work has just been issued. Prof. Nolan and a corps of experts have rewritten the book from cover to cover and it is a veritable digest of the latest approved practice in all branches of the Building Trades.

The authors have quoted from many authentic sources as well as giving the results obtained in their own daily practice. Every item has been carefully checked and rechecked to see that it is technically correct and the aim throughout has been to present clearly and concisely and in the least possible space, all the information that is likely to be required by the architect, builder, structural engineer, draughtsman or contractor, including data for estimating the approximate cost.

This New Kidder is divided into three sections: *Part I*, which contains 90 pages, explains the practical application of arithmetic, geometry and trigonometry. This data has been carefully checked and much of the matter rearranged. *Part II*, with its 1324 pages, treats the materials of construction and strength and stability of structures. All the matter in the 28 chapters included in this section are special essays by experts. Reinforced Concrete Mill and Factory Construction is one of the new subjects given in this edition. *Part III*, contains 358 pages of miscellaneous data and much new matter has been added such as extended tables of specific gravities, weights of substances, architectural acoustics, waterproofing for foundations, the new quantity system of estimating, etc.

One of the most important changes is the recalculation of the tables and problems relating to unit stresses, especially those for the different woods. These were changed to conform to the latest engineering practice. The derivation of many of the formulas used has been explained, and numerous cross references enable the reader to use the New Kidder as a text book for

certain parts of the mechanics of materials as well as a handbook for office work. The tables of the properties of structural shapes, of safe loads for columns, beams and girders have been revised and many new tables added.

Many of the tables have been rearranged so as to read across the page instead of lengthwise as heretofore. A large number of illustrations have been added and the diagrams used from the last edition have been redrawn and some have been printed with lines of different colors to make the demonstrations clearer.

Every paragraph of the text starts with a black faced caption describing the subject matter of the paragraph the same as in Arthur's New Building Estimator. This facilitates quick reference. An elaborate cross reference index of 40 pages set in two columns is also provided. The subjects covered in every paragraph have been carefully indexed and cross-indexed so the reader will be sure to find any item he is likely to look up, at a glance.

Special Offer. We will stamp the customer's name in gold without charge on all copies of this book ordered through us.

CONTENTS OF NEW KIDDER BY CHAPTERS

PART I—PRACTICAL ARITHMETIC, GEOMETRY AND TRIGONOMETRY (90 Pages)

Mathematics.
Weights and Measures.
The Metric System.
Conversion Tables.
Mensuration and Geometry.
Geometrical Problems.
Table of Chords.
Hip and Jack-Rafters.
Trigonometry, Formulas and Tables.

PART II—STRENGTH OF MATERIALS, CONSTRUCTION AND STABILITY OF STRUCTURES (1324 Pages)

Terms Used in Architectural Engineering.
Foundations of Buildings.
Masonry Walls. Footings for Light Buildings. Cements and Concretes.
Retaining-Walls, Breast-Walls and Vault-Walls.
Strength of Brick, Stone, Mass-Concrete and Masonry.
Forces and Moments.
Stability of Piers and Buttresses.
The Stability of Masonry Arches.
Reactions and Bending Moments for Beams.
Properties of Structural Shapes, Moment of Inertia, Moment of Resistance, Section-Modulus and Radius of Gyration.

Resistance to Tension, Properties of Iron and Steel.

Resistance to Shear. Riveted Joints. Pins and Bolts.

Bearing-Plates and Bases for Columns, Beams and Girders. Brackets on Cast-Iron Columns.

Strength of Columns, Posts and Struts.

Strength of Beams and Beam Girders.

Framing and Connecting Steel Beams.

Strength of Cast-Iron Lintels and Wooden Beams.

Strength of Built-Up, Flitched and Trussed Wooden Girders.

Stiffness and Deflection of Beams.

Strength and Stiffness of Continuous Girders.

Riveted Steel Plate and Box Girders.

Strength and Stiffness of Wooden Floors.

Wooden Mill and Warehouse-Construction.

Fireproofing of Buildings.

Reinforced-Concrete Construction.

Reinforced-Concrete Factory and Mill-Construction.

Types of Roof Trusses.

Stresses in Roof-Trusses.

Wind-Bracing for Tall Buildings.

PART III—USEFUL INFORMATION FOR ARCHITECTS, BUILDERS AND SUPERINTENDENTS (358 Pages)

Heating and Ventilation. Heat, Fuel,

Water, Steam and Air Chimneys.

Hydraulics, Plumbing and Drainage.

Gas and Gas-Piping.

Lighting and Illumination of Buildings.

Electric Work for Buildings.

Architectural Acoustics.

Data on Excavating.

Stonework.

Bricks and Brickwork.

Lime.

Sand and Gravel.

Lathing and Plastering.

Lumber and Carpenters' Work.

Building Papers, Building Felts and Quilts.

Paint and Varnish.

Window-Glass and Glazing.

Asphaltum.

Mineral Wool.

Structural Steel.

Estimating the Cost of Buildings.

Quantity System of Estimating.

Mail-Chutes, Elevator Installation.

Mechanical Refrigeration.

Tower-Clocks.

The Classical Orders.

Lightning-Conductors.

Vacuum-Cleaning.

Waterproofing of Foundations.

Horse-Power, Pulleys, Gears, Belting and Shafting.

Chain-Blocks.

Hoists and Hooks.

Architectural Terms Used in Law, etc.

1812 Pages 4 1/4 x 7 inches 1000 Figures Flexible Morocco with Gilt Edges, \$5.00

BUILDING AGE BOOK DEPT., 239 West 39th Street, New York

Shoreview Apartments, East Delaware Place, Chicago, Ill.
Architects, Eckland, Fugard & Knapp, Chicago.
Contractors, McLennan Construction Co., Chicago.
Consulting Engineers, Lieberman, Klein & Hein, Chicago.

There's Strength and Economy in a Floor Like This—It

- reduces dead floor load by eliminating unnecessary concrete,
- is fireproof and soundproof,
- saves in concrete reinforcing steel,
- is adaptable for light and heavy long span construction,
- minimizes cost of centering and form work,
- is easily and speedily put in place.

Berger's Pressed Steel Cores

will do all this—being scientifically designed to give the greatest strength and displacement for the least amount of weight and cost.

Made from sheet metal, formed from one piece and corrugated, making them very rigid and stiff. Made in depths of 6, 8, 10 and 12 inches and lengths up to 3 feet. Standard width, 20 inches.

We make both permanent and removable cores. The heavier gauges can be removed and used over again indefinitely.

Before building, investigate Berger's Pressed Steel Cores. Send for full particulars and Catalog F. B.

The big Edwards' Metal Shingle family is growing fast. One of our late arrivals is here shown. Look it over. Did you ever see a more handsome, novel design, or more clean cut embossing? We've christened this "Baby" after our own great state.

Edwards "Ohio" Metal Shingle

This stunning pattern is made in one size only, 14 x 20 inches. Manufactured from the best quality Worcester Grade Terne Plate, painted or "Tightcote" galvanized. Every good Edwards Shingle feature—and there's a big bunch of them, including our

famous patent interlocking device—is in the "Ohio," of which we are justly proud. *Let Us Send Samples and Agent's Proposition*—The high quality of the former will please you and the low prices will surprise you. You ought to see the "Ohio" and you ought to see it now. Act!

There's Just One Roof

that combines

Beauty, Safety and Economy

When you roof a building with Ambler Asbestos Shingles "Century Brand," you can safely give a guarantee that as long as the walls stand there'll be a roof overhead—a fireproof, weather-tight, cyclone-defying roof, which will not fade, crack, peel, expand with summer's heat or contract with winter's frost.

AMBLER Asbestos CENTURY BRAND Shingles

*The Roof That Is as Permanent
as the Foundation*

give your customers a degree of protection and economy impossible with any other type of roofing. Ambler Asbestos Shingles "Century Brand" are made of Portland cement and Asbestos fibre, built up layer upon layer, and, under terrific pressure, are pressed mirror smooth, and free from air-holes. The asbestos fibre reinforces the cement as steel rods do a wall.

Firebrands fall harmlessly on these shingles; the heaviest gales will not loosen them; summer's scorching sun nor winter's tightest freezes will not cause them to warp, split, crack or deteriorate in any way. On the contrary, Ambler Asbestos Shingles grow tougher and stronger with exposure. They always look like new; they come in the following attractive, natural, non-fading colors: Indian Red, Newport Gray and Blue Black. The first cost is the last, as repairs are eliminated.

Let us send you our literature, samples and pictures.

Again!
Another New
FLEX-A-TILE

It's simply a variation of our Diamond Slab. Identical in quality, materials and wearing properties—but different in shape and appearance.

**Style 4
Slabs**

This newest style Flex-A-Tile Asphalt Shingle meets the requirements of those who prefer the appearance of rectangular shaped single shingles but who want the economy and convenience of Flex-A-Tiles in slab form.

As the illustration shows, this Flex-A-Tile Style 4 Slab is really four shingles in one. The 4-inch long slits act as a score to lay to, as well as to mark the usual spaces that occur between single shingles. You simply cannot distinguish a roof of Flex-A-Tile Style 4 Slabs from a roof of single shingles. And of course these Style 4 Slabs are laid quicker, cheaper and last at least as long as single shingles. Size of each slab 32 x 10 inches. Surfaced with the usual Flex-A-Tile red or green stone surfacings.

Truing Up

IN truing up a job the carpenter, cabinetmaker or patternmaker depends upon the accuracy of his tools.

Every workman in wood or metal whose work requires careful measurement and absolute precision knows that he can depend upon

Starrett Tools

True Tools for True Work

Every carpenter's tool kit should include some of these accurate instruments. For example, the combination square can be used in many ways for "truing up"—as a rule, a try square, spirit level, marking gage scribe, depth gage to measure in mortises, height gage and center head.

Other Starrett tools for woodworkers are

REX STRIP SHINGLES

Will not blow up in the wind because the spaces between the shingles do not extend under the shingles in the course above, and so there is no opening for the wind to get under them and lift them. This is why Rex Strip Shingles make a tighter roof than any individual shingles.

Ordinary concrete, uncoated, showing its porous character.

Concrete finished with Bay State Coating, making it waterproof.

Building for Beauty

To fully realize the possibilities of concrete and stucco, you should know the ideal effects which are get-able with

Bay State ^{Brick and} Cement ^{Coating}

This Coating overcomes the dull blue-gray of concrete. It gives a permanent finish in white or tint. It doesn't sacrifice the distinctive texture of concrete.

Also—Bay State Coating makes an absolutely weather-proof wall. Rain can't seep through the pores.

Architects and builders in all parts of the country have tested this, the original Bay State Coating. We'll be glad to pass along what they say of it. Write for booklet 19.

Or, test it yourself—we will send you a sample can of the original Bay State Coating free for the asking. Say what tint you prefer.

It can't fall

The keystone in an arch is no more securely held in place than is the stucco finish on a background of Bishopric Board. In both, the age-old and reliable principle of dovetailed construction insures security.

is built on the wisdom of ages. Dove-tailed lath, creosoted to preserve them, imbedded in asphalt-mastic, a perfect protection against vermin and dampness; backed by heavy fibre-board, through which neither sound, heat nor cold can penetrate, form a background for stucco, cement or plaster combining the oldest and most

efficient principles in building construction. Bishopric Board will not corrode—it cannot break away or sag.

Write for free samples and our book "Built on the Wisdom of Ages." It illustrates homes, apartments and buildings of all kinds using Bishopric Board. It contains scientific tests, with letters from architects, builders and users; and it gives facts and figures to prove that Bishopric Board cuts the cost twenty-five per cent.

Write today for proof of every claim made.

"Famous"

**For the Large or Small Contractor
In the Shop or on the Job**

The Famous Universal Woodworker is a machine whose multiplicity of utility makes it an asset potent in its advantages.

So designed that almost any desired equipment may be combined in one machine, and thirty or more different kinds of work can be done successfully by one equipment.

The impossibility of this accomplishment on any other machine is well known.

The Sidney Tool Co., Sidney, Ohio

Stearns

No. 10

Give Your Floors a Good Shave at Our Expense

The Stearns scrapes them clean and smooth and scrapes without those wavy lines so often caused by chatter.

There are exclusive features galore in the Stearns, No. 10, adjustable handle, rubber tires and the way the weight is thrown on the knife. The double-edge knife wears twice as long as the ordinary kind.

Take the machine and compare its qualities with those of any other Scrapers. Study the prices and details.

Sold by dealers direct from the factory or on fifteen days' trial.

Write for details.

E. C. Stearns & Co.

400 Oneida St., Syracuse, N. Y., U. S. A.

Why Break Your Back?

IMPERIAL
FLOOR SANDER

PRICE
\$5.00

Use the Imperial Floor Sander

No more aching knees or back. The Imperial Floor Sander makes floor surfacing easy. Simply a push and a pull and it does the work well.

Load it with twelve sheets of sandpaper. When one sheet wears out cut it off without removing the binder. Don't hesitate to tackle varnish. The Imperial will remove it; it will also resurface and wax floors.

Any carpenter can afford it. Only \$5.00. Does the work of an expensive power machine.

If your dealer doesn't handle the Imperial, we will send one direct upon the receipt of \$5.00.

Here's a Typical Day's Work

Federal Trucks have brought better haulage methods and increased business to their users to such an extent that over 60% of them have ordered "another Federal."

One reason for this remarkable satisfaction in the Federal product is shown by this typical day's work of Federal No. 3249 operated by the Phelan and Faust Paint Mfg. Co.

Trips	7	Miles per pint of oil.....	45.85
Deliveries	18	Operating cost per day (includ-	
Additional stops	11	ing driver)	\$6.14
Total day's deliveries, lbs.....	15,450	Cost per ton (delivered 5 miles) ..	.79
Miles traveled	36.3	Cost per delivery.....	.34
Miles per gallon of gas.....	7.64	Weight per delivery, lbs.....	850

Perhaps a Federal would prove a money-saver and a money-maker in your business. Let our traffic department furnish you with exact data on what Federals have accomplished in the building trade. Write for the new "Blue Book of Traffic" and Special Contractors' Folder.

FEDERAL

"THE STANDARD" Low Charging Mixers and Equipment

Mixers—The low, compact design of "The Standard" makes it unnecessary to use any kind of mechanical devices to charge the materials into the mixing drum. The mixer is charged direct by wheelbarrows by wheeling up short runways on to a platform only 24" high. The elimination of side loader reduces the weight of the complete outfit about one-third, making it easy to move along the work as it progresses or from one job to another. The thorough mixing action, the semi-automatic discharge, the portability as well as the low charging and light weight are features you should investigate.

Catalog No. 48-9 gladly mailed upon request.

Hoists—The use of gasoline hoists in building and a great variety of other work is rapidly increasing. Gasoline power is desirable on account of the low first cost, the small expense for attendance and operation and the light weight, enabling the outfit to be placed in the most convenient position for economical work, while shipping and handling expense is very moderate. "The Standard" Reversible Hoist is the most popular size for operating two platform material elevators, and is also used for direct hoisting with single line. We can also furnish hoists in both single and double drum with 4 to 15 H.P. Engine and with capacities from 800 to 5000 lbs.

Pumps—It has been demonstrated that power pumps will lift many times the volume of water with greatly reduced cost over pumping by hand. "The Standard" Diaphragm Pumping Outfit is especially constructed for easy moving, being extremely simple and light in weight, yet strongly constructed, and is recommended for pumping muddy and gritty water from trenches, cellars, etc., and for use on cofferdams, etc.

Wheelbarrows and Carts—Our wheelbarrows and carts are characterized by sturdy construction and designs in which the wheel carries greatest possible amount of the load, and are consequently easy to handle and are the best adapted for concrete and building work.

Conservation and Efficiency— the Watchwords of this Wonderful 20th Century

And the mission and PURPOSE of the Bessler Movable Stairway is to conserve—that is to say—save space, and do it in a practical and efficient manner.

The Bessler Movable Stairway

This stairway is designed to replace the stationary stairway to attics and lofts in buildings of two stories and more. And in bungalows it provides a splendid stairway to the half-story above.

Not a single square foot of floor space is wasted in the lower room, as when the Bessler Movable Stairway is not in actual use, it is swung up into the ceiling—out of the way. Nothing is then visible in the ceiling except a neat panel finished to match the wood-work in room.

Write Us for Our Booklet

It fully describes this wonderful space saver and gives photographic views of it in various positions. At the same time we'll be glad to quote you prices.

It Is Strong and Sturdy

That fact is brought out in the picture alongside. Note the easy slope of the stairs. A child can operate it. It is fully guaranteed in every respect.

OAK FLOORING "AMERICA'S Best Flooring"

Landlords and builders offering houses for sale or for rent command the highest of rentals and hence, the highest class of tenants. They always emphasize OAK FLOORING in their ads in newspapers.

$\frac{3}{8}$ " OAK FLOORING offers a beautiful and very economical floor at a low cost. It is the ideal flooring for laying over old floors in churches and homes. When laid, it has all the appearance of 13/16" stock. $\frac{3}{8}$ " is made in 1 $\frac{1}{2}$ " face and 2" face.

Contractors and carpenters find it very profitable in soliciting the laying of $\frac{3}{8}$ " OAK FLOORING in old homes during slack periods. Any carpenter, exercising a little care, can lay OAK FLOORING successfully. 95% of modern houses now have OAK Floors. OAK FLOORING is always considered the very best kind of investment.

All reputable lumber dealers sell OAK FLOORING.

*These fire-safe shingles
are easy to lay and
profitable to handle*

Shrewd builders who have sensed the trend toward fire-proof construction are making two profits on

JOHNS-MANVILLE Transite Asbestos Shingles

—one on the sale and one on the laying. These shingles are profitable in a broader sense, too, because they satisfy both parties—builder and client.

The builder adds to his profit on each job a reputation for service which will sell more roofs. The client gets a roof that is safe, sightly and permanent—free from repair expense—and cheaper than slate or tile.

J-M Transite Asbestos Shingles *can't* burn, and actually toughen with age—won't warp, rot, split, or curl. Made in various sizes, shapes, and colors, permitting attractive and distinctive treatment.

Get your name on the J-M mailing list, write the nearest J-M Branch for samples and for information of our dealer proposition.

J-M Transite Asbestos Shingles are examined, approved, and labelled by the Underwriters Laboratories, Inc., under the direction of the National Board of Fire Underwriters. Laid American method they are given Class "B" rating. Laid French method they are given Class "C" rating.

Profitable to You and Your Customer

Your greatest asset in business is the satisfaction of your customer. Give him what he wants at the price he wants to pay, and you've really *doubled* your profit.

For building construction, whether exterior or interior, you can specify

North Carolina Pine

"The Wood Universal"

with the assurance that your customer will be *more* than satisfied, both from the standpoint of economy and of appearance.

North Carolina Pine is today being more widely used than ever before. Its beauty and variety of grain adapt it most admirably to interior ornamentation. Its use for exterior purposes demands only the same discriminating care in selection and protection as other woods under similar conditions. *It has proven its worth in both fields.*

Write for Our Instructive New Book

We have compiled an elaborate and exhaustive booklet on North Carolina Pine for the information of contractors, builders and architects. It shows you most emphatically that "the wood universal" is a wood *most profitable*—to you and your customer. Write today for free Reference Book B.

NORTHROP, COBURN & DODGE CO.

43 Cherry St., New York

"Stucco Coated frame residence" from July Building Age. Geo. J. Hardway, architect.

"The shingles of the roof were dipped 10" in Cabot's Shingle Stain before being laid, and they were given a brush coat when the house was finished. The stucco finish received two coats of Cabot's Stucco Stain."

Cabot's Shingle Stains

They have been the standard for more than twenty-five years, and are specified by nine-tenths of the architects, who know them from experience. Their colors are soft, rich and beautiful, and guaranteed fast. Their vehicle is Creosote, which thoroughly preserves the wood, and they contain no kerosene or other cheapener. Why experiment with unknown stains, when you are sure of Cabot's?

Cabot's Stucco Stains

are the only artistic cement finishes. They give soft, natural coloring effects, without covering the surface with a painty coating. They are also cheaper than coatings and easier to apply, and they cannot crack or peel.

You can get Cabot's goods all over the country. Send for samples and name of nearest agent.

Second Floor Plan—Scale $\frac{1}{16}$ In. to the Foot

Plans, Elevations and Details of a Frame House at Bayside, Long Island, N. Y.

give to it an individuality highly creditable to the architect responsible for the conception.

The arrangement of rooms is decidedly out of the ordinary. Leaving the broad porch, the visitor enters from the vestibule into a reception hall practically square in size and having at the front a cozy nook lighted by a double window. The stairs are of the combination type and rise from the reception hall three steps to a broad landing, which is also reached by a similar number of steps from the kitchen hall. From the landing the stairs turn at right angles to the left and bring one to a second broad landing lighted by an outside window, and the flight, then turning to the right, brings one to the hall on the second floor in the center of the house.

At the right of the reception hall and communicating with it through a buttressed opening, is the living room, the striking feature of which is the

another in the "Den," which is at the right of the dining room and communicates with it through casement doors on either side of the fireplace.

The kitchen is located at the rear directly beyond the reception hall and at the left of the dining room with which it communicates through a well-equipped butler's pantry. The kitchen has a separate chimney for the range, and the wash trays and sink are placed under one of the side windows where they receive ample light. The refrigerator occupies a space directly off the kitchen and is lighted by an outside window.

There is an entrance to the kitchen at grade and from it the cellar is reached by a flight of stairs directly under the main flight to the second floor.

In the second story are four sleeping rooms and bathroom. A feature worthy of special mention in this connection is the separate toilet which im-

A Frame House at Bayside, Long Island, N. Y.—Architect George J. Hardway, New York City

massive stone fireplace and chimney breast, a view of which is afforded by the picture upon the first page of this article. At the left of the fireplace are seen the bookcases with high window above, and in the background to the left is a glimpse of the dining room with its brick-faced fireplace with "summer piece" in position. Another feature of the living room is its beam ceiling.

Beyond the living room is the dining room with its bay-window and fireplace as already noted. One of the pictures presented herewith represents a view in the dining room looking toward the china closet, and showing through the partially opened casement door, the desk and bookcase in the "Den." At the extreme left is the other door leading into the "Den," while at the extreme right is a glimpse of the fireplace in the living room.

Backing the fireplace in the dining room is

mediately adjoins the bathroom. The sleeping room at the rear has an open fireplace and it is from this chamber that the sleeping porch is reached through double casement doors. Each sleeping room has a commodious clothes closet and in the hall near the bathroom door is a linen closet.

The foundation walls of the house are of concrete, composed of one part cement and five parts coarse gravel and sharp sand. The cellar has a floor of concrete 4 in. thick. The chimneys are built of hard-burned brick set in lime and cement mortar. The flues have terra cotta lining extending from the bottom to the top.

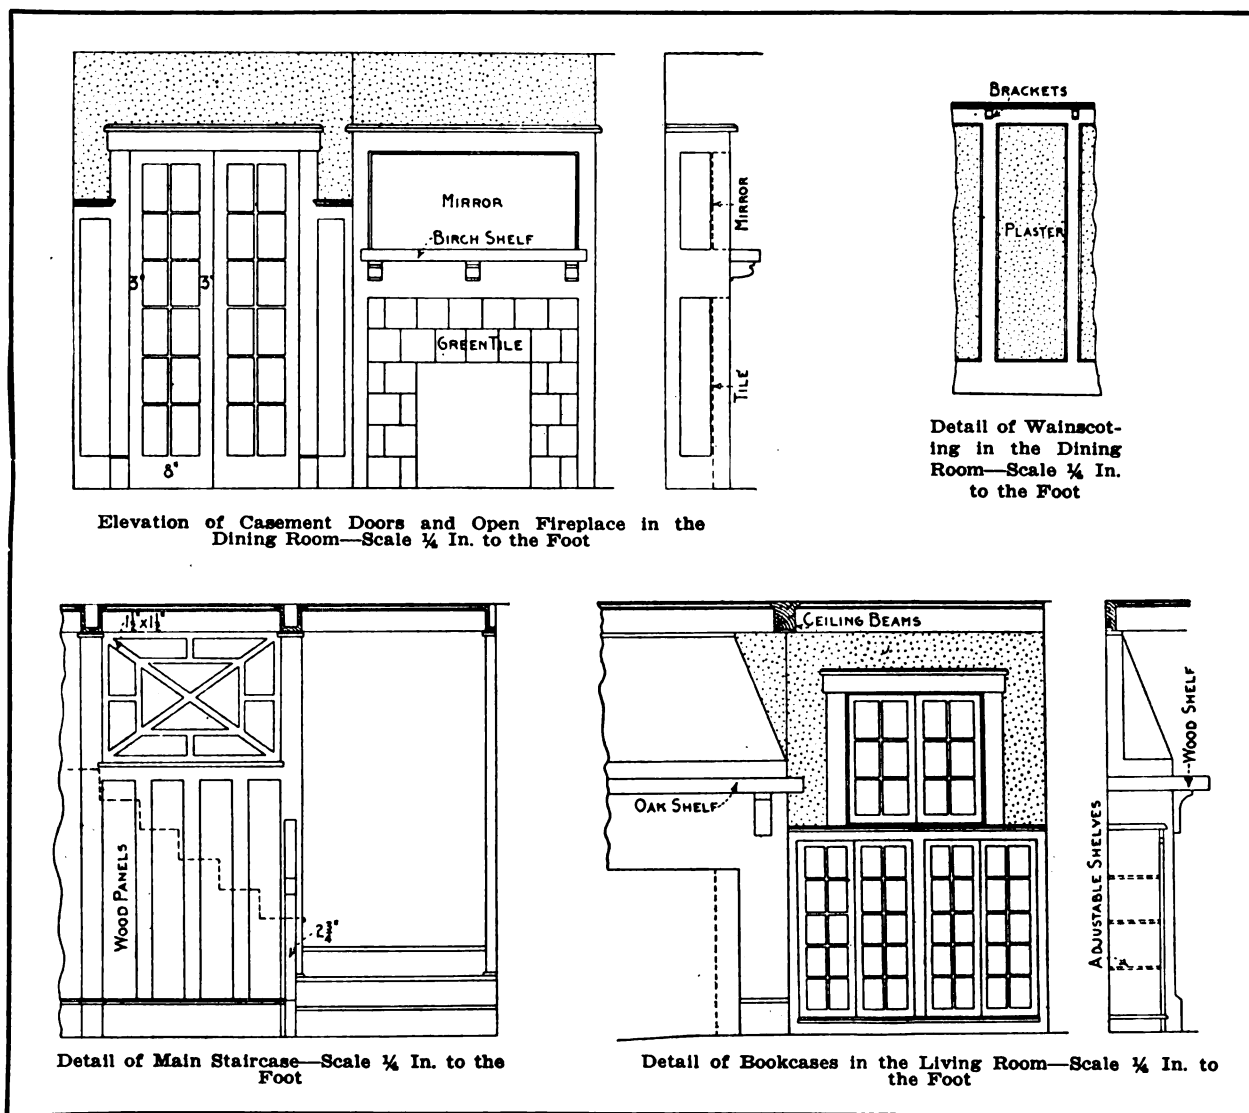

The floor of the front porch, or as it may be more strictly termed "veranda," is of concrete 4 in. thick, resting on a cinder base, with a 1-in. layer of Portland cement as a top dressing.

Of the framing members, the sills are 4 x 6 in.

with girder 6 x 6 in. The sills are halved and spiked together at the corners and supported on Acme columns with iron caps and bases. The first and second floor joists are 2 x 10 in. and those of the third floor 2 x 8 in., all spaced 16-in. on centers. They are doubled under partitions and around openings for stairs, chimneys, etc., and with headers and trimmers hung in stirrup irons. The studs and plates are 2 x 4 in. and the rafters 2 x 6 in., also spaced 16 in. on centers. The floor joists of the porch decks are 2 x 8 in., spaced 16 in. on centers. All framing is diagonally braced with 2 x 4-in.

tion of the kitchen and the pantry are double. The sub-floor consists of $\frac{7}{8}$ x 6-in. spruce boards, laid diagonally, over which is a finish floor of oak parquetry. The floors of the kitchen and pantry are $\frac{7}{8}$ x 2 $\frac{1}{2}$ -in. matched maple. The floors of the second story are of $\frac{7}{8}$ x 2 $\frac{1}{2}$ -in. face edge-grain North Carolina pine, while the floor of the third story is 4-in. North Carolina pine.

The finish of the living room, reception hall and stairs is of $\frac{7}{8}$ x 4 $\frac{3}{4}$ -in. oak, with molded cap. The dining room is finished in birch treated in imitation of mahogany. The finish of the kitchen is of

Miscellaneous Constructive Details of a Frame House at Bayside, Long Island, N. Y.

pieces cut in between studs, and floor joists are braced with 1 $\frac{1}{8}$ x 2-in. herringbone bridging.

The exterior framing is covered with $\frac{7}{8}$ x 8 -in. matched and surfaced spruce boards laid diagonally, over which are 22-in. cedar shingles exposed 9 in. to the weather.

All roofs are covered with 16-in. cedar shingles exposed 4 in. to the weather.

All outside finish, corner boards, casings, moldings, exposed rafters, pergola members, etc., are of No. 1 cypress. The porch ceilings are laid with cypress ceiling strips having 2 $\frac{1}{2}$ -in. face. The porch columns are of the lock-joint type, made by the Hartmann-Sanders Co., Chicago, Ill.

The floors of the first-story rooms with the excep-

cypress, and the same material is used for the finish of the third story.

The doors, with the exception of the front entrance are 1 $\frac{3}{4}$ in. thick and of the five cross-panel type. The window sashes are of white pine 1 $\frac{3}{8}$ in. thick and the French windows are 1 $\frac{3}{4}$ in., rabbetted and hinged at the side.

All exterior woodwork received a priming coat and then two coats of white lead and oil paint. The ceiling of the porch was finished with a coat of bleached shellac and two coats of varnish. The front door was finished with spar varnish.

The shingles of the roof and the sides of the house were dipped in Cabot's silver gray shingle stain and afterward received a brush coat. All interior trim

received four coats of pure flat white finish. The white wood and birch were fumed and stained mahogany, and then given three coats of rubbing varnish, which was finished with pumice stone and water. The white cement tile of the bathroom was given three coats of "Superior" white enamel, over one coat of flat "Jap-a-Lac." The exterior of the bath tub was finished in the same manner.

The bathroom equipment consists of modern plumbing fixtures, the lavatory being of oval pedestal style, 22 x 33 in. in size and of enameled iron. The tub is of the rolled rim iron enameled type, 5½ ft. in length and provided with claw feet. The toilet immediately adjoining the bathroom has a syphon water-closet of vitreous china with mahoganyized birch seat and cover. The servants' bathroom on the third floor is fitted with a 4 ft.

all fixtures as well as to the heater and laundry stove. A sill cock is provided at the front and rear of the house with a shut-off in the basement.

The attractive suburban home here illustrated and described is known as "Greenwood Lodge" and was built for Arthur Swann, Odell Avenue, Bayside, Long Island, N. Y., in accordance with plans prepared by Architect George J. Hardway, 347 Fifth Avenue, New York City.

Decorative and Enduring Qualities of Cypress

A wood that is beautiful, workable and lasting is sure to be valued by architects, carpenters, and cabinet-makers, for these three qualities are not always found combined. Such a wood as this is cypress—

A Frame House at Bayside, Long Island, N. Y.—View in Dining Room Looking Toward the "Den" with the Living Room at Right

6-in. enameled iron tub and an enameled iron washstand measuring 18 x 20 in. The water-closet is of the same style as that already mentioned. In the basement is a wash-down water-closet with an oak seat and cover.

The sink in the kitchen is of enameled iron with flat rim and measures 20 x 30 in. in size.

The house is heated by a hot-water system with bronzed radiators, the boiler used being of the Richardson & Boynton make. All pipes supplying radiators above the first floor are run in partitions and are covered with heavy asbestos. The boiler and all basement pipes have magnesia covering.

Water and gas pipes were carried in from the street 5 ft. below grade. A main shut-off for water is located just inside the front wall of the house in the basement and from this are carried ¾-in. galvanized iron water pipes to supply cold water to

hence its wide renown and popularity to-day. Yet there are still many home-makers who are not familiar with all of its virtues, and a few words upon the nature and usefulness of this adaptable material may prove of timely interest to those who contemplate the building or remodeling of a home.

Cypress should not be used indiscriminately; it need not be employed where cheaper woods might acceptably serve. Yet it is coming more and more to be chosen in places where "good enough" lumber is not so much the object as permanent investment value. For cypress adds so definitely to the value of a structure that builders prefer it for many purposes in place of other woods.

If one does not wish to use it solid, one can employ it as a sort of preserving veneer for the interior trim, shutting out from woods that are less durable the elements of destruction and safeguard-

ing them from decay. Likewise applying the "exterior veneer" principle, every builder may insure his work against rot and other forms of deterioration by "veneering" the house with cypress—which means using it for all outside woodwork. It is the exposed woodwork that bears the brunt of the attack, and the wise general masses his greatest defensive forces at the exposed posts.

The safety of the building, however, is not assured by using cypress for this purpose only. There are other places that should be guarded. The chief one is where the frame structure joins the foundation—the sills or bearing plates. These rest on the cold, damp material of which the foundation is made. They serve as the super-foundation of a frame building.

Weight of Building Carried on the Sills

The entire weight of the building is carried by these sills. There are many points of contact between the sills and the studding, each one of which is a point of attack for destroying fungi, says Arthur S. Devose in a recent issue of *The Craftsman*. The foundation usually transmits the necessary moisture to feed the fungi, and the result is deterioration, slow at first, but more rapid as the destroying agent strengthens its hold.

Destruction of wood at this point is commonly attributed to "dry-rot"—a somewhat misleading term, for utter absence of moisture or complete submersion in it renders wood impervious to decay. Certain wood-destroying fungi thrive with a minimum of moisture and where they secure a foothold "dry-rot" is said to have set in. Cypress is relatively impervious to rot influences, and for this reason is recommended by its historic achievements for duty at all exposed points.

The extra cost of the absolutely necessary quantity of cypress for a house—its cost being somewhat higher than many woods—is almost negligible. If cypress is specified and included in the estimate, it means usually only a slight difference in price, sometimes none at all. Here are actual figures:

Amount Required for the Sills

Take an ordinary house with, say, 150 ft. of outer wall. Using one piece of 2 x 12 and one piece of 2 x 10 for a box sill, it would require 550 ft. of lumber for the sills. If it was necessary to pay as much as \$20 a thousand feet more for the cypress, the cost of the whole building would be increased only \$11. Surely that is a very small premium to pay for insurance against the necessity of putting in a new super-foundation for the entire structure, repair work that would cost several hundred dollars plus untold inconvenience.

Thousands of builders, however, have begun to use cypress for exterior woodwork as a matter of economy. They consider it the best investment they can make. For interior woodwork it meets with greater competition, as many other woods will give ample length of service where not exposed to weather. But the advent of the "sugi" finish, which gives the world-famous Japanese "driftwood" effects, has added to the natural virtues and interesting grain of cypress the possibility of strikingly decorative beauty. This is secured in a simple manner. The surface of the wood to which it is to be applied is charred with a gasoline torch and the

charred portions brushed away with a steel brush.

Cypress is being used, moreover, in increasingly large quantities for greenhouses; in fact, it has almost a monopoly of that trade. It is also becoming popular for pergolas, sleeping porches, rustic siding, arbors, trellises and other uses where the wood is exposed to alternate extremes of temperature and moisture. For such purposes its rot-proof qualities have made it the general favorite.

Working Unit Stress for Structural Timbers

This table gives working unit stresses for structural timbers used in dry locations, and is compiled in the main from material furnished by the Forest Products Laboratory, Madison, Wis. Other values of unit stresses for use in the various formulas will be found in the same table. The unit bending stress may be taken from the table, according to the kind of timber used.

Working Unit Stresses for Structural Timbers Used in Dry Locations

Species of Timber	BENDING		COMPRESSION	
	Stress in Extreme Fibre, Lbs. Sq. In.	Horizontal Shear Stress, Lbs. Sq. In.	Parallel to Grain "Short Columns," Lbs. Sq. In.	Perpendicular to Grain, Lbs. Sq. In.
*Fir, Douglas				
Dense grade	1,600	100	1,200	350
Sound grade	1,300	85	900	300
Hemlock, Eastern	1,000	70	700	300
Hemlock, Western	1,300	75	900	300
Oak	1,400	125	900	400
Pine, Eastern White	900	80	700	250
Pine, Norway	1,100	85	800	300
*Pine, Southern yellow				
Dense grade	1,600	125	1,200	350
Sound grade	1,300	85	900	300
Spruce	900	70	600	200
Tamarack	1,200	95	900	350

*The safe working stresses given in this table are for timbers with defects limited according to the sections on defects in the rules of the Southern Pine Association for Select Structural Material. "Dense" Southern yellow pine and "dense" Douglas fir should also conform to the other requirements of this rule. "Sound" Southern yellow pine and "sound" Douglas fir require no additional qualifications, whereas the other species should, in addition to being graded for defects, have all pieces of exceptionally low density for the species excluded.

Cottages of Reinforced Concrete Built in Four Hours

Attractive summer cottages of reinforced concrete are being constructed so rapidly on the shore of Lake Erie, near Cleveland, Ohio, that approximately only four hours are said to be required to erect one. Steel faced "forms," which can be quickly put up or taken down, are used for the foundation, floor, walls, partitions and roof, which are of "poured" concrete construction. The concrete is discharged into these "forms" from the mixer by means of an inclined adjustable trough, the aggregate being conveyed up the trough by metal paddles arranged endless-chain fashion and then is chuted through a spout to the point required. After the forms are removed, the interior surface is smoothed and subsequently painted.

The cottages are one story in height and occupy an area of 35 ft. in length by 21 ft. in width. The walls are 4 in. thick and the ceilings are 9 ft. high. A flat parapetted roof is covered with earth which serves as an insulator against the heat of the sun.

The floor plan of each home provides for a large living room so arranged that it may be subdivided should necessity arise; a bed chamber, kitchen and toilet room.

A "Field House" and Comfort Station

A Design Well Adapted for a Small Park—Details of Construction with Reference to the Plumbing

THROUGH the activities of Park Commissioners in many Middle Western cities the small parks, squares and triangles under their jurisdiction have been improved by the erection of inexpensive comfort stations, the providing of sanitary facilities for men and women being a distinct benefit to the public and reflecting no little credit on the designers. Buildings of this character combine features of interest to the builder, and a knowledge of the requirements should be of material assistance to the individual in the preparation of plans and specifications. The presentation of the

structure that would enable visitors to obtain a splendid view of the surroundings and enjoy the cool breezes in summer, besides providing a structure that would be a shelter against rain storms and a convenient place where meetings may be held. Should firework displays be held at any time there is little danger of fire, as asphalt shingles have been used in covering the roof.

The subject of this article is an attractive one-story building designed along conservative architectural lines and including many interesting constructive features. In the first picture there is pre-

Fig. 1—Photographic Perspective View Showing Front and Side of the Building

following data is an opportunity for the progressive contractor to bring before the proper authorities in his home city the advantages and low cost of erecting similar buildings wherever needed.

The Park Commissioners of Herrington's Island Park in Geneva, Ill., a town of 2500 population, have recently completed the construction of a field house and comfort station on the banks of the beautiful Fox River, the work being an interesting example of what the contractor in the country town is called upon to execute for a sum approximating \$5,500. The location of the building was an additional inducement for the architect to design a

sented a general view of the west and south sides of the building taken from the bank of the river. The exterior treatment involves the use of face brick and stucco which harmonize with the asphalt shingles. The architectural lines are enhanced by the dormers on the east and west sides. A wide terrace having three arched openings gives access to a spacious loggia. On the south side is the entrance to the boys' toilet rooms, the door being concealed by the outer walls. In the third picture the rear of the building is shown. At the extreme left are seen a number of barricades resting against the terrace. These were provided by the contractor

being so arranged that the summer breezes will sweep through to the far terrace from off the river.

Running parallel with and on either side of the loggia are the boys' and girls' toilet rooms, the arrangement in each case consisting of a large outer room and a smaller toilet room. The sections housing the plumbing fixtures measure 16 ft. square, while the outer rooms measure approximately 16 ft. wide by 28 ft. long.

Access to the toilet rooms is made possible from either the loggia or the exterior of the building, the outside entrances being concealed by brick walls. A stone slab built into each wall denotes whether it is the girls' or the boys' section. Each room is lighted by four windows, four to each side of the building, making sixteen windows in all. The equipment in the girls' toilet room consists of four closets and three lavatories, while the boys are pro-

The cement floors of the loggia, the terraces and terrace steps have a $\frac{3}{4}$ -in. finish of one part Portland cement, two parts coarse sand and 5 lb. of master builders' red concrete hardener to every bag of cement. This hardener was used to reduce the glare of the finished concrete and also to harmonize with the face brick work. The aggregate was thoroughly mixed until uniform in color, sufficient water being added to thoroughly saturate the mixture. For the finish a dry mixture consisting of one part master builders' red concrete hardener and one part Portland cement was mixed to an even color and sprinkled evenly over the surface. This was floated in thoroughly and well troweled. A second troweling was given the surface after it had set sufficiently to finish hard and smooth. For safeguarding the floor, it was specified that after the top surface had set the contractor cover it with

A "Field House" and Comfort Station Fig. 2—A Detail of the Front Terrace

vided with four urinals, three closets and two lavatories, as well as a slop sink.

All foundation walls and piers are of concrete, consisting of one part Portland cement and six parts gravel of medium size, with footings 1 ft. 4 in. The exterior surfaces of all walls above grade and above the finished floor lines are troweled smooth with cement plaster.

The floor of the building and terraces is of concrete 4 in. thick, resting on a 6-in. bed of cinders. A cement base is built around the loggia and cement steps for the terraces and exterior toilet entrances. The proportions of the aggregate for concrete are the same as those in the foundation work. The floors in the toilet rooms and their communicating steps have a $\frac{3}{4}$ -in. cement finish, composed of one part Portland cement and two parts sand.

a uniform layer of non-staining soft wood sawdust or shavings. This was not applied until experiment showed the surface hard enough to prevent the covering from scratching or injuring the finish. The surface was kept wet for no less than five days.

The terrace floors are graded to a 4-in. pitch and brick drips are provided in the terrace walls. Stone was used throughout for the terrace copings and for the 5-in. fireplace mantel.

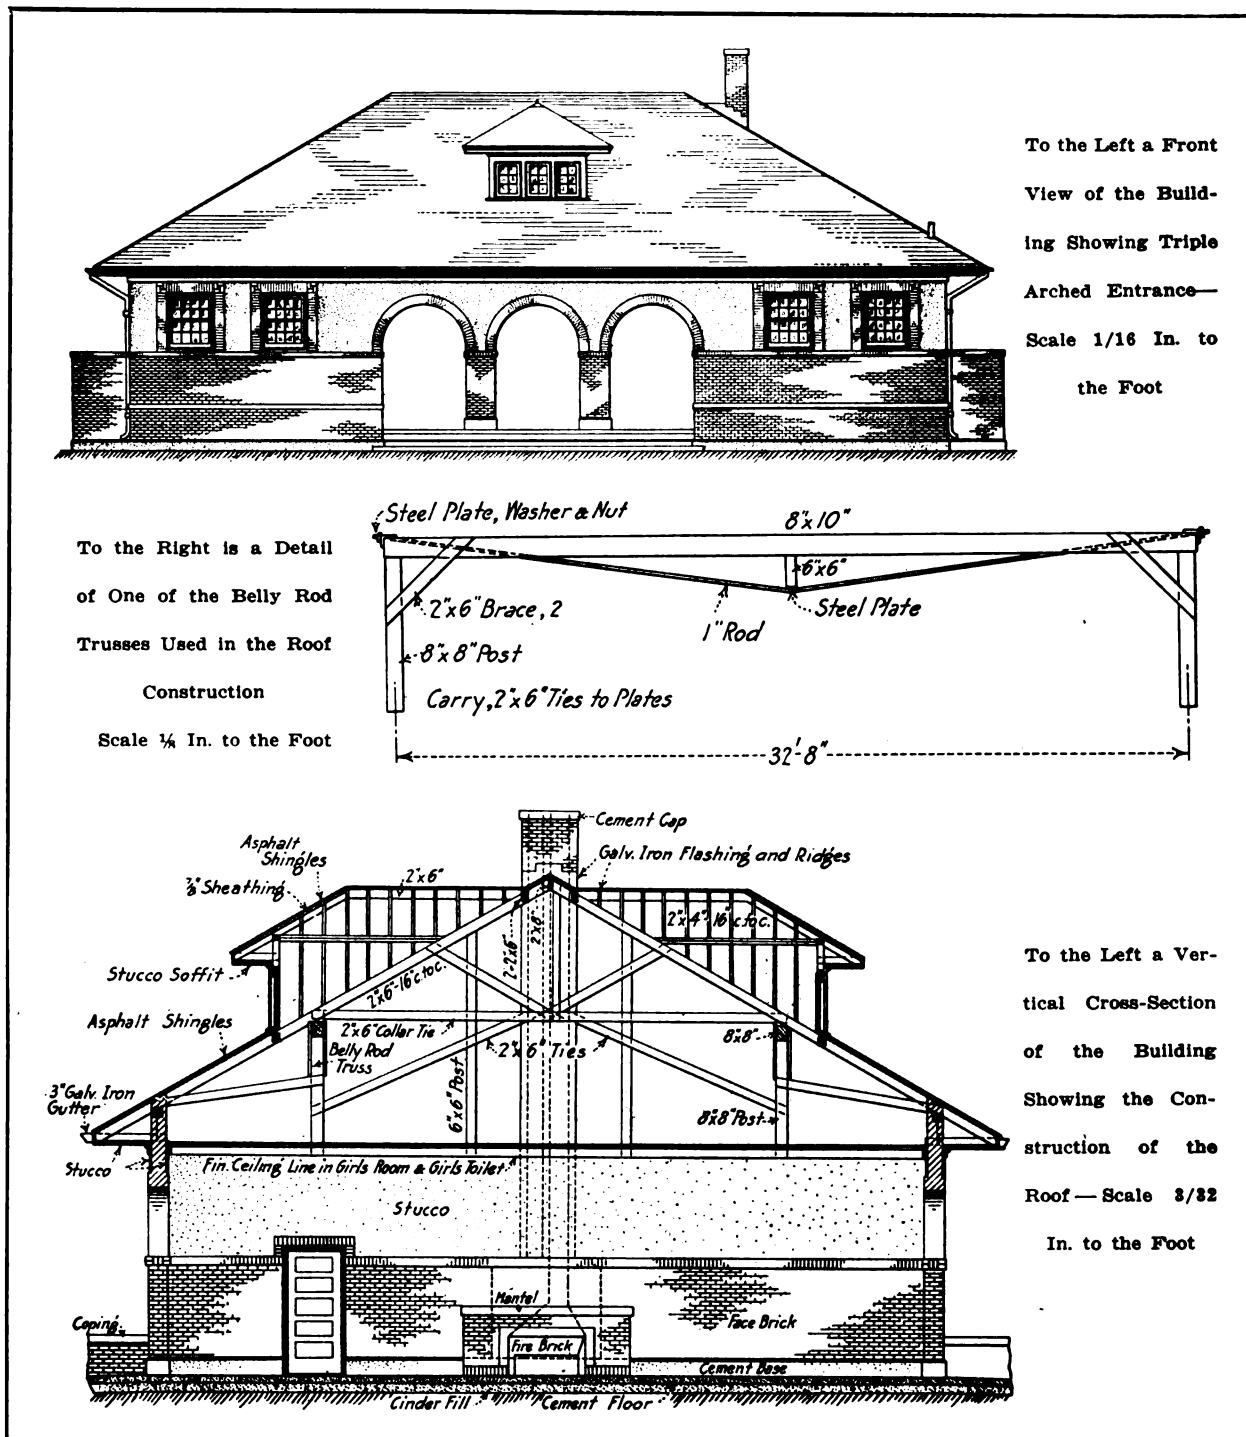

All brick walls backing up face brick and interior brick walls in the toilet rooms are built of first quality hard burned common Illinois brick, with struck joints. The bricks are laid in solid joints of tempered lime mortar, every seventh course being a header course.

The exterior surfaces of all walls, the fireplace, the chimney above the roof and all loggia walls are

finished with a rough face, wire cut Arcadians mixture brick, all face brick being laid in regular bond with $\frac{3}{8}$ -in. uniform raked black joint. Face brick is used for the copings on the walls concealing the toilet entrances. The face brick walls are extended to a height of 8 ft., above which point are hollow tile and stucco work. The outside brick walls are 13 in. thick. Window sills inside and out are

course is carried inside and out, with stucco on common brick between.

The walls above the brick work are of 12 in. "Natco" hollow tile, laid in tempered mortar. The partition walls between the outer and inner toilet rooms are 8 in. thick and built of hollow tile. The ceilings of the toilet rooms and the soffits of the building and dormers are covered with expanded

A "Field House" and Comfort Station—Elevations and a Detail of the Roof Truss

built of brick. The edge of the roof extends 3 ft. beyond the exterior walls.

The chimney and fireplace are of face brick, and the flues are lined with cement plaster. The chimney is capped with 5 in. of cement and is lined and floored with firebrick laid in fire clay. The fireplace is 10 ft. wide and 4 ft. high.

The inner circle of the arched openings is 3 ft. 6 in. in diameter, over which a face brick soldier

metal lath. Six inches of stucco is provided above the brickwork over the windows. The ceilings and soffits and all walls outside and inside above face brick are plastered two coat work.

The plates in the hollow tile wall are 2 x 6 in. and the bolts are $\frac{5}{8}$ in., 18 in. long, and placed 10 ft. on centers. The rafters are 2 x 6 in., placed 16 in. on centers, with braces and collar ties. The four hip rafters are 2 x 10 in. and the ridge is 2 x 8

in. The collar ties spanning the width of the building above the belly-rod trusses are 2 x 6 in. The $\frac{7}{8}$ x 6 in. ties shown in the sectional elevation are nailed to every fourth rafter. Dormer rafters are 2 x 4 in., placed 16 in. on centers.

In the attic space over the toilet rooms are two 6 x 6 in. posts supporting the hip rafters, placed 8 ft. apart, the posts extending to a height of 12 ft. above the finished ceiling line of the toilet rooms. These posts are also 8 ft. distant from the 8 x 8 in. posts forming part of the belly-rod trusses.

The belly-rod trusses extend the entire width of the loggia beneath the dormers and are 32 ft. 8 in.

Fig. 3—Rear View of the Building

Fig. 4—View in Loggia Looking Toward the Front Terrace with the River Beyond

built of $\frac{7}{8}$ -in. M & V pine, the doors being of the same material.

All exterior woodwork received two coats of white paint after priming. The surfaces of sheet metal work, plumbing pipes and window gratings have one coat of zinc white mineral paint mixed with boiled linseed oil and two coats of white lead paint. The pulley stiles received one coat of boiled linseed oil when the frames were primed and one coat when the finish was applied. All interior doors, sash, toilet partitions, etc., have two coats of white lead paint.

The closet compartments are 4 ft. wide, 5 ft. long and 6 ft. high. Connections for water supply are made with the city water main about 50 ft. north-east of the building. A 2-in. galvanized iron pipe is run to a 24-in. manhole in a corner of the girls' toilet room, where the piping and valves are exposed. From the 2-in. water main proper connections are made to the various fixtures. All plumbing fixtures are of types made by the Standard Sanitary Mfg. Co., Pittsburgh, Pa.

The lavatories are equipped with self-closing

Fig. 5—Closet Compartments in the Girls' Toilet Room

A "Field House" and Comfort Station—Various Pictures of Interest to the Builder

long. The 8 x 8 in. posts at either end are joined by an 8 x 10 in. beam securely braced at each end with two 2 x 6 in. pieces, the 2 x 6 in. ties being carried to the wall plates. The distance between the 8 x 10 and the low point of the 1 in. belly rod is 18 in., and this is reinforced by a 6 x 6 securely fastened to the rod by a steel plate. Where the rod joins the truss at the top of the posts it is securely held in place by a steel plate equipped with washers and nuts.

The roof is sheathed with $\frac{7}{8}$ x 6 in. No. 2 pine boards laid close together, which, with the dormers, are covered with Barrett's "Tyle-Like" slate colored asphalt shingles exposed 4 in. to the weather.

The doors throughout the building are of types made by the Curtis Door & Sash Co., Chicago, Ill. The outside toilet doors measure 3 x 7 ft. x $1\frac{1}{4}$ in., and the closet compartment doors are $\frac{7}{8}$ in. thick, of the same length and width. Toilet partitions are

nickel-plated faucets. The urinal stalls are built of slate and the urinals are operated by an intermittent self-operating tank. The closets are equipped with galvanized iron low-down tanks, painted white, and seats which automatically flush the bowl when released after use.

The soil and waste pipes are of extra heavy cast iron with hub joints. The plumbing system is vented and revented, as shown on the accompanying floor plans. The water closets and urinals have 4-in. wastes and the rest of the fixtures 2-in. wastes. The vent stacks continued through the roof are flashed and covered with sheet lead, leaving an air space between the lead and the cast-iron pipe.

The wastes from the building are carried through a 4-in. cast-iron main to a heavy concrete catch-basin located near the building. From the catch-basin a vitrified tile sewer makes connection to the city septic tank.

The building is wired for electric lighting in accordance with the rules of the Board of Fire Underwriters.

The plans and specifications of the building were prepared by Frank B. Gray, 1251 Otis Building, Chicago, Ill., who places the cost of the structure at \$5,445. The general contractors executing the work were Wilson Bros. of Geneva, Ill.

Liquids for Use in the Drafting Room

A liquid may be obtained which enables blue print copies to be made of letters, printed pages from books, heavier grades of tissue drawings, etc. It may be applied to many articles of this kind from which blue print copies could not otherwise be made, as the application renders them transparent, without in any way damaging the article itself, beyond a slight coloring and stiffening of the paper. If this is objectionable it may be removed by applying gasoline to the paper. This cuts out the oil left by the liquid, and restores the article to its original condition.

The application of this non-inflammable compound to pencil drawings on cloth or paper will render these drawing materials transparent, and blue prints may be made in electric frames at the same speed as from ink tracings. This eliminates the old pencil lay-out and reduces the cost of labor and material in preparing drawings from 30 per cent to 50 per cent, depending upon the extent to which the idea is carried out. Brief directions for the preparation of these direct pencil drawings are given below.

(a) Drawings on cloth or paper should be made with the "HB" or "2-H" grade of pencils, the former for the heavy view lines and shading and the latter for the finer and dimension lines.

(b) The drawing when completed should be laid face down on a clean table and the liquid applied by a brush which will transparentize the drawing and grip the pencil lines. The drawing should then be thoroughly coated on face side and dried between blotters; care should be taken to see that any excess solution is blotted from the surfaces.

(c) The solution protects the drawing from smudging of the pencil lines and successful erasing of any considerable portion of the drawing can only be done with benzine and a soft cloth. When new views are laid in on such cleaned portions, the solution should be applied to both sides of the drawing, the same as the original application.

(d) The completed drawings may be handled the same as ink tracings and blue printed at the same speed but are more durable for records as they are water-proof and do not wrinkle.

As regards the transparentizing solution. It has no objectionable odor; does not evaporate after application; does not require heating before application; will have no deteriorating effect on cloth, paper or any materials to which it may be applied. It is entirely safe to handle, is not gummy and does not require the addition of alcohol or similar materials from time to time to prevent gumming.

In addition to its use as outlined above it is indispensable in the drawing room for the following named purposes.

Old or soiled tracings may be thoroughly cleaned and transparentized by applying this solution to both sides with a soft cloth and drying with blotters or cloth.

Sepia negative prints on cloth or paper, and black or brown line positive prints from Sepias, may be transparentized and blue prints secured in the same time as required for making prints from ink tracings.

Printed or typewritten matter, either original or carbon copies may be transparentized and blue prints secured at the same speed as from ink tracings, which makes it invaluable for the preparation of specifications, which it is desirable to produce in blue print form.

The liquid may be applied to tracings damaged by water and the difficulty in securing prints from such tracings may be overcome.

Another useful article to a drafting room may be secured in the way of a liquid to repair holes in tracing cloth. It will repair any torn spots, and will cause holes almost $\frac{1}{4}$ in. in diameter to entirely disappear from the tracing, by forming a coating where the hole formerly was. Ink may be used directly over the hole or on any of the repaired spots without danger of spreading over the cloth.

A number of concerns now manufacture liquids which will remove all errors from tracings. These solutions will not rot the cloth nor cause the same to deteriorate, but leave the surface of the cloth in its original condition. Directions as follows:

Saturate a small soft clean rag with a few drops and apply to the lines to be erased by a gentle rapid rubbing until the erasure is complete. Then with a dry clean rag apply benzine until all traces of the ink are gone. Never rub hard or use a hard cloth.

Stains from fruit, coffee, etc., may also be removed from paper, clothing or fingers by one of these solutions.

Suggestions for Treatment of Interiors

In the issues of the paper since May we have presented each month four pages of well-executed engravings carrying suggestions for modern door and doorway treatment, together with designs of lighting fixtures and door hardware appropriate to the present tendency in these lines.

In the present issue and beginning on the facing page we show a series of excellent interiors with varied styles of finish all calculated to prove of suggestive value to the architect, the builder and the interior decorator.

The series includes dining rooms, living rooms and staircase hall, the treatment in some instances representing the very latest vogue in this line.

On the fourth page of the series are two views of an impressive entrance of a country home in one of the boroughs of Greater New York. The treatment about the doors is especially noticeable.

The old brick walls of a building which is being converted into a theater in Oakland, Cal., have been perforated by hammer and chisel, the little cavities thus made being intended to serve as a binder for the stucco surface.

The Steel Square and Roof Framing

A Method Which May Be Regarded as an Excellent Key to the Use of the Steel Square

By C. J. M.

SO much has been said and written on this subject that it would seem superfluous to discuss the matter further; but there are a few points on which additional comment may not be considered out of place. It is generally conceded that the steel square is a handy instrument to use in cutting the frame work of a roof, and especially if one has first learned how to cut the frame without it. How were all the roof frames cut before the steel square was invented? Everyone knows that there were many roofs framed before that time, and some of them at least show that the work was well done. There were certainly good roof framers in the days of our grandfathers who had some sure method of performing the work which they were called on to do.

Instead of putting the steel square stumbling

steel square in his "kit," although he was far from being ignorant of its uses. The methods used by this man are simple and easy to understand, and may be shown clearly within the limits of a drawing board 18 x 24 in. in size. As this method is the very best key to the use of the steel square, it may be interesting to the young readers of THE BUILDING AGE. I will therefore present drawings illustrative of these methods as I learned them and by practice proved them to be correct.

Referring to Fig. 1, A-B-C-D represents a drawing board 18 in. wide and 24 in. long. I may say here, however, that there is no particular reason for having a board exactly this size, as its dimensions have no bearing on the work to be done, so that any board or number of boards put together for the occasion will serve the purpose so long as it is large enough and smooth enough to lay out the lines correctly. Now, suppose we have an L-shaped roof to

Fig. 1—Method of Finding the Length of the Common and Hip or Valley Rafters

Fig. 2—Diagram of Roof with Six Hips and One Valley

The Steel Square and Roof Framing—By "J. C. M."

block in the way of the young carpenter, why not teach him the old method of doing the work? Instead of telling him that the length of the common rafter on the blade and the run on the tongue gives the mark for the cut of jack rafters to fit against hip or valley rafter, why not teach the young man how to make a plumb miter cut on a raking piece of timber, for that is exactly what it is?

Now as to those old methods of roof framing, I expect the present-day carpenters have been puzzling their brains so much with the figures for the cuts on the steel square that they have forgotten all about them, simple as they are. Now, the steel square is a capital instrument for those who know how to use it and know why they take certain figures on the blade and tongue to obtain certain cuts. I have met very few who possess this knowledge, although I have known a man who could cut the frame of the most complicated roof and have all his lengths and cuts correct without such a thing as a

frame with the ends hipped. The portion forming the "L" is considerably narrower than the main portion of the building, this making it necessary to use six hip rafters and one valley rafter, as shown in Fig. 2, which represents a plan of the roof. It makes no difference what may be the length or width of the roof—all that is necessary for our purpose is to know the rise of the roof per foot run.

Again referring to Fig. 1, we have the triangle *a-b-D*, of which the side *D-b* (12 in.) represents 1 ft. of run and the side *D-a* (8 in.) the rise for 1 ft. of run. The side *a-b* (14 7/16 in.) represents the length of the rafter for each foot of run; and we know if we multiply 14 7/16 in. by the number of feet in the run of the rafter, or half the width of the roof, we will get the length of the rafter from the outside of the wall to the center of the ridge. If there are odd inches in the run add a fraction of the 14 7/16 in, corresponding to the fraction of a foot contained in the odd inches. For example, if

the run be 10 ft. 8 in., or $10 \frac{2}{3}$ ft., multiply $14 \frac{7}{16}$ by 10 and add two-thirds of $14 \frac{7}{16}$ in., which may be easily obtained by dividing the line $a-b$ of Fig. 1 into three equal parts, using a pair of dividers. The equivalent of any fraction of a foot may be obtained in this way.

For obtaining the plumb and level cuts, set a bevel to the angle a for plumb cut and to the angle b for level cut. So much for the common rafter.

In roofs of equal pitch on both sides of the hip the run or seat of the hip rafter stands at an angle of 45 deg. to the seat of the common rafter; in other words, it is the diagonal line of a square.

Again referring to Fig. 1, we have the right angle triangle $c-d-C$, the sides of which forming the right angle at C are each 12 in., and the third side, $c-d$ (17 in.), shows that 17 in. is the diagonal measurement of a foot square and, being so, is the equivalent in the run of the hip rafter for 1 ft. in the run of the common rafter. We have also in Fig. 1 the right angle triangle $A-e-f$, with a run 17 in. and a rise 8 in., which gives 18 $\frac{1}{2}$ in. as the length of the hip rafter for each foot of run of the common rafter. We may obtain the full length by the means explained above in the case of the common rafter. It should be said that the figures given in connection with Fig. 1 are not mathematically correct but are sufficiently so for all practical purposes.

In order to obtain the bevel for the cross-cut of jack rafters, proceed as follows: Fig. 3 shows the right angle triangle $a-b-D$ of Fig. 1, which gives the level and plumb cuts of the common rafters. Draw the line $c-d$ parallel to $a-b$ to represent the thickness of the timber used. Square across from a to c ; on the line $D-b$ set off $D-e$ equal to the thickness of the timber and draw the line $e-f$ parallel to $a-D$. Connect c with f ; then the line $c-f$ is the cross-cut for

Fig. 3—Method of Finding Cross Cut for Jack Rafters

The Steel Square and Roof Framing—By "J. C. M."

the jack rafters. Set a bevel to the angle formed by $f-c-d$.

By a similar process we obtain the cross-cut on the hip or valley rafters where they fit against the ridge or against each other. Hip and valley rafters should always be measured on a line in the center of their thickness, the reason for which will be explained as we proceed.

In Fig. 4 we have the right angle triangle $e-f-A$ of Fig. 1, only for convenience it is shown with the angle e pointing in the opposite direction; $e-A$ (8 in.) gives the plumb cut and $A-f$ (17 in.) gives the level cut of the hip or valley rafter. In this case we lay off $g-e$ for the thickness of the timber and $m-l$ the center line, parallel to $e-f$. Now square across $g-e$ and lay off the distance $A-j$ equal to half

the thickness of the timber and draw $i-j$ parallel to $e-A$. Through m draw $i-h$; then the line $i-h$ is the cross-cut required. Set a bevel to the angle formed by $g-h-i$.

In roofs where the rafters are allowed to project beyond the wall plate to form projecting eaves it is a mistake to consider the top of the wall plate the height of the wall. It is this consideration that affords occasion for the use of the so-called "working line" and what a recent writer was pleased to call the "mathematical ridge." The outside edge of the wall plate is not the point where the wall finishes and the roof begins, but rather where the plumb line cuts the back of the rafter. The length of the rafter should be laid off from this point. What remains of the plumb line above the wall plate or seat of the rafter should be considered as being added to the height of the wall. In this way we lay off the length of the rafter in the right place—from the outside of the wall to the ridge. An illustration of this is shown in Fig. 5, which needs no comment.

Fig. 5—Showing How to Lay Off the Length of the Rafter in the Right Place

Fig. 4—Method of Obtaining the Cross Cut on Hip and Valley Rafters

In Fig. 6 is shown the seat notch in the common rafter where it fits over the wall plate. It will be observed that there are 4 in. of the plumb line left standing above the seat line. This need not be followed in all cases; but whatever is here, it is absolutely necessary that it should be the same in all the rafters, as shown in Figs. 6, 7 and 8. In cutting the seat notch in the hip rafter after the length is laid off on the center line, as from m (Fig. 4) to d (Fig. 8), which shows the seat notch of a hip rafter, square across at d and make the plumb line $a-c$. Back on the rafter half the thickness of the timber from $a-c$, draw another plumb line $e-f$, and upon this last line lay off the distance left plumb over the seat line on the common rafter and draw the seat line at right angles to it. Cut by the first plumb line $a-c$.

Fig. 7, I think, tells its own story and needs little explanation.

It will be seen that *d* (Fig. 8) is the lower extremity of the rafter. Square across at *d* and draw the plumb line *e-f*. Upon this lay off the proper height and draw the seat line. Now add to the seat line half the thickness of the timber *f-g* and draw the cutting plumb line *a-c*. In the case of a hip rafter like that shown at *B* (Fig. 2), the rafter is measured on the center line and the extreme height squared across, as at *d* (Fig. 9), and the plumb line *e-f* drawn. On each side of this line lay off half the thickness of the timber and draw the plumb lines *a-b* and *g-h*. On the line *g-h* lay off the proper height and mark the seat line. A bevel set at the angle formed by *c-a-g* gives the mark for the cut to fit against the wall plate.

The valley rafter shown at *A* (Fig. 2) should be measured in the ordinary way and the seat notch

the blade and the run of the common rafter on the tongue, etc., etc."

Now, this run of the common rafter, to my mind, seems irrelevant to the work in hand. We are treating the plane of the roof of which the backs of the jack rafters form a part. Why, then, go around the job looking for the figure on the tongue of the square when we have it right before our eyes? Now, it is not what a person says that counts so much as the manner in which he says it. If those who profess to know things and teach them to others would explain *why* this or that is thus, it would be better for those whom they wish to teach.

Let us, for example, take a young man on the job with us to cut the frame of a roof. We will say that he is a pretty studious young fellow and very anxious to learn, but as yet knows nothing about the job only what he has learned from his own ob-

Fig. 6—Seat Cut of Common Rafter

Fig. 8—Seat Cut of Hip Rafter

Fig. 7—Seat Cut of Valley Rafter

Fig. 9—Showing the Rafter Marked for Thickness of Timber and Plumb Lines

The Steel Square and Roof Framing—By "J. C. M."

made as shown in Fig. 7. The upper end, where it fits against the rafter *B*, is a square plumb cut. The measurement gives the length to the center of the rafter *B*; therefore, half the thickness of it must be taken off the rafter *A*—not off its length, but measured at right angles to the plumb cut.

The length of all rafters is measured from the outside of the wall to the center of the ridge; therefore, where a ridge board is used half its thickness measured at right angles to the plumb cut must be taken off all rafters butting against it.

In explaining the use of the steel square, some would-be teachers use expressions which, if not misleading, are at least puzzling to the uninitiated. For example, "to obtain the cuts for cripples (jack rafters), take the length of the common rafter on

servation. We place a steel square in his hands, and say:

"Here, start and cut those jack rafters."

We give him the figures on the square for the plumb and level cuts. Yes, he can understand that all right; the plumb and level cuts are square with each other. We give the figures for the cross-cut thus, "the length of the common rafter on the blade and the run of the common rafter on the tongue." He takes the square in his hands, looks at it, then his mind's eye falls upon the common rafter and the relation of its length to its run.

"Hang it! The run of the common rafter is not at right angles to its length, and how am I to reconcile that to my square? It may be right, but I don't understand it."

"No," we say; "it certainly needs explanation before you can be expected to understand it. But it is correct, all the same. Now, look here. You see this little diagram; it is just four lines of equal length forming a square, with one diagonal line drawn to opposite corners. Now, the diagonal line represents the run of the hip rafter. These two sides of the square meeting at this end of the diagonal line represent the run of two common rafters—one each side of the hip. The two sides of the square meeting at the other end of the diagonal line represent the portion of the wall plate within the run of the hip rafter, or the length of wall plate forming the base of the triangle to be filled in with jacks. You see, it is exactly the same length as the run of the common rafter; that is why we take the run of the common rafter with the length."

A light kindles in the young man's eyes, a smile plays around the corners of his mouth.

"Yes, yes; I can see it now, all right. If I lay the blade of the square along here by the edge of the wall plate the blade runs up the side of the rafter. Thanks, Boss, for that explanation; it's worth dollars to me, and so easy to remember."

Largest Office Building on Pacific Coast

What is said to be the largest office structure west of the city of Chicago is the new building about to be erected in San Francisco, Cal., for the Southern Pacific Railroad Company. It will be of steel skeleton frame construction with curtain walls of concrete and brick and the face will be brick and terra cotta. The nature of the ground, formerly tide land, requires careful foundation work, and 2123 piles each 115 ft. long will be driven to bed-rock under the footings.

The structure will be 10 stories in height with deep basement, will be in the shape of an "E," the back extending the length of the block on the south side of Market Street from Stewart to Spear Streets, a distance of 275 ft., the depth on the two side streets being 209 ft., and the estimated cost fully \$1,250,000.

The feature of the front will be a row of terra cotta columns and arches, extending to the top of the second story. The main entrance on Market Street will be full two stories in height, with a lobby finished in white marble. All corridors will be floored with marble, and the woodwork throughout will be oak.

Bliss & Faville are the architects, and the first actual construction will be done by the Van Sant-Houghton Company, which has the contract for piling, concrete caps, footings, etc.

The Most Costly Woods

It has been claimed that the small piece of spruce used in the manufacture of a high-class violin is the most costly wood in the world. The test is not fair. It is the work bestowed on the wood, and the name of some famous maker associated with it, that give the spruce in a violin its value. The test is the wood bought in the rough, before any value has been added by manufacturing. Measured in that way, spruce, even the finest that the market affords, does not measure in value up to a number of other woods.

A value of \$100 a thousand feet would be excessive.

It is not possible to say what is the cost of any wood. The cost varies with time, place, and quality. Very fine samples may sell for two or three times as much as ordinary samples of the same wood. The fairest method of coming to a price is to take averages in a good market during a considerable period of time, and the cost should be at wholesale, so far as the wood has a wholesale value.

Calculated in this way the list which follows gives some of the costliest woods in the American market, but not all of them. Doubtless some which are not in the list are as expensive as some that are there, but the list will answer the general purpose of showing the range of expensive woods in the market. The figures are taken, for the most part, from reports of wood-using industries of either New York or Illinois, and are the average prices paid during one year. They should, therefore, be fairly representative. All of the values are based on the basis of 1000 ft., board measure. Some expensive woods are bought and sold by the pound, but where price is given it is calculated on the basis of 1000 ft.

The following list of woods and prices is compiled from actual purchases:

Wood	Cost per 1000 Feet	Wood	Cost per 1000 Feet
Mahogany	\$140	Cocuswood	\$275
Cocobal	160	Vermillion	300
Madagascar tulip	180	African walnut	\$21
Donsella	203	English oak	340
Rosewood	220	Amaranth	400
Teak	262	Turkish boxwood	400
Circassian walnut	275	Sandalwood	400
Ebony	275	Satinwood	400
Australian plum wood ..	275	Snakewood	575

Every one of the foregoing woods is foreign. Black walnut is usually credited with being the most expensive wood of the United States. The claim probably holds good if only woods in general use are considered. Mesquite lumber, sawed for furniture, sells for more than black walnut, but it is not regularly in the market and is sawed to order and in small amounts only.

The Highest Priced Wood

In searching for the highest priced wood in the world, according to present markets, says *Hardwood Record*, the honor will doubtless fall on malacca (*Calamus scipionum*). This is neither a hardwood nor a softwood, but a climbing palm found in the jungles of Siak on the island of Sumatra. It is used for canes. The choice stick for a cane is cut from between the joints of the palm, and must be 40 in. long. That length is quite unusual, and long search is required to find one. It is said that from 50,000 to 100,000 pieces must be sorted to find one that is perfect. However, good prices are obtained for those which are not faultless, and it is not necessary to throw away imperfect stock. When a perfect specimen is found it is handled with the greatest care, for it is worth almost its weight in gold.

A malacca cane of fair quality sells for \$50, while the best, with artistic taper and perfect crook, is worth \$125. If the stock in such a cane is reduced to board measure, and the value figured on that basis, it is found that it is worth the enormous sum of \$700,000 the thousand feet. No great part of this is due to cost of manufacturing, but can be charged to the expense of finding the high-grade stock in the jungle and taking it to market.

An Eighteenth Century Roof Truss

The Framing Is a Combination of Several Styles but the King-Post System Predominates

AN elaborately and scientifically designed roof will always attract a considerable amount of attention, and to those who possess technical knowledge, and who are conversant with the theory of framed and braced structures, is an object of interest, and intensely absorbing from various points of view. The workmanship will be carefully examined if circumstances permit, and the design studied with interest, the observer tracing the means by which the weight is distributed through the various portions of the structure, until it is ultimately deposited vertically on the supports.

At Stratfield Saye House, celebrated as the Hampshire residence of the Dukes of Wellington, is

ably on the tie beams. The whole of the roof, with the exception of the wall plates and keys, is of fir, and is in a very fair condition structurally, although some parts are considerably worm eaten and crumbling on the surface.

The workmanship, as is usually found in most timber constructions of this date, is rough, no pretensions being made to a particularly fine finish.

The joints at the lower end of all vertical members are secured with a mortise and tenon, but in no case, except at the intersection of the principal rafters with the king post, and at the posts at the extreme ends of the tie beam, is the top of these members provided with any fixing beyond a plain

Some Interesting Details of an Eighteenth Century Roof Truss

a large building, the roof framing of which is shown in the accompanying illustration. The method of framing adopted appears to be a combination of several styles, in which perhaps the king-post system predominates, says a writer in *The Illustrated Carpenter and Builder* of London. The illustration, which is drawn to scale from measurements taken from the roof itself, will show the general construction, the size of all timbers being marked on each member.

The building itself, which is 110 ft. long by 42 ft. wide, was originally erected for a riding school more than 100 years back, but has since been adapted for use as a covered tennis court, with a stone flagged floor. It is similar in design and construction to the one at Hampton Court, and was probably remodeled and laid out as a replica of that building at some later date. The height from floor to under side of tie beam is 21 ft. 3 in.

There are nine roof trusses, spaced 10 ft. 3 in. apart, the principal rafter having a pitch of 40 deg. with the horizontal. The timbers are mostly sawn, but in some cases the adze marks may be seen, not-

butt joint, held in position by an iron strap.

The position of the purlins varies in the actual roof, and they are only indicated approximately on the drawing as regards both position and construction, owing to the difficulty experienced in obtaining a satisfactory inspection of anything outside the principal rafter. The roof is boarded with $\frac{7}{8}$ -in. fir boards, and as these are flush with the back of the principal rafter and are carried across on a level with, and supported by, the small member marked 3 in. by 4 in. to form a ceiling, access to all parts beyond this boarding is very limited. The collar beam is strengthened at each end as shown by an 8-in. by 6-in. beam, which is placed underneath, the two being connected by means of 1-in. iron bolts and oak keys, and supported by two short posts.

All the iron stirrups and straps are out of $2\frac{1}{4}$ -in. by $\frac{1}{2}$ -in. wrought iron. They are expanded at the bolt hole in order to strengthen the bar at this point. The ends of each strap are caulked, and, as an additional fixing, a square staple is driven into the timber astride the strap and close up to the caulking. The bolts are all 1-in. in diameter, with

2¼-in. square nuts. No provision is made for tightening up the joints of the framing by means of wedges or joint bolts. The tie beam being 3 in. thicker than the other members, as shown on the section, is mortised through its depth on each side, and the stirrup passed up through the mortise and connected with the posts as described, thus weakening the beam as little as possible. The ironwork is very primitive, both in its construction and application, the heads of the bolts in particular being hand forged to a rough mushroom shape.

At the right of the elevation it will be seen that the roof is carried on a 5-in. by 15-in. oak plate, which in its turn is supported by an 18-in. brick wall.

On the opposite side the wall terminates about 4 ft. below the tie beam, and the 8-in. by 8-in. wall

plate is carried on a series of posts of the same dimensions standing on the wall, one post being placed under each truss. The tie beam and wall plate are connected by iron angle plates and bolts.

The space between the top of the wall and the plate is left open the whole length of the building for the admission of light and air. On the right-hand side a large skylight is inserted in the roof between each pair of trusses, and is flashed with lead in the usual manner. The roof is covered with duchess slates, with sheet lead hips and ridge.

The design of the roof cannot be considered as economical, nor yet to be of a handsome appearance. Viewed from the ground it appears massive, especially as the more open part at the top is partially hidden by the ceiling, allowing only the lower and more complicated portions to be in evidence.

Details of Bay Window Construction

Manner of Making Frames in the Planing Mill and the Trimming of Them on the Building

BY JOHN WAVREK, JR.

FROM time to time there have appeared in various publications devoted to the woodworking interests, valuable contributions concerning the making of window and door frames. These have shown that what one man has regarded as a very good construction some other capable worker has pointed out wherein the method was lacking, at least according to his own experience, and has endeavored to show a form of construction which he considered more efficient as well as more economical. These little controversies are as they should be because they are the means of bringing out the best possible results in frame-making, laying bare, oftentimes, some weak part of their construction and showing how they may be greatly improved. There is, however, one phase of the window frame work which has been very little considered, and that is, the construction of bay window frames in the planing mill and the trimming of them on the building itself.

In the sketches presented herewith I have endeavored to show as clearly as possible the different methods of construction of bay windows as they are made in the section of Pennsylvania in which I reside. There has been made no effort to show the best possible way of placing the rough frame work because that is really the province of the carpenters who work on the building. It is my aim to show the make-up of the different frames best suited for the openings as provided by the carpenter together with the trim to complete the job and make a neat piece of work.

Referring to the sketches, Fig. 1 shows the floor plan of a style of bay window which is very extensively used; in fact, there are few houses of the regular run which do not include a bay of this kind in the design. Fig. 4 represents a half inside and half outside elevation of the window when completed by the carpenter. In this instance 2 x 4-in.

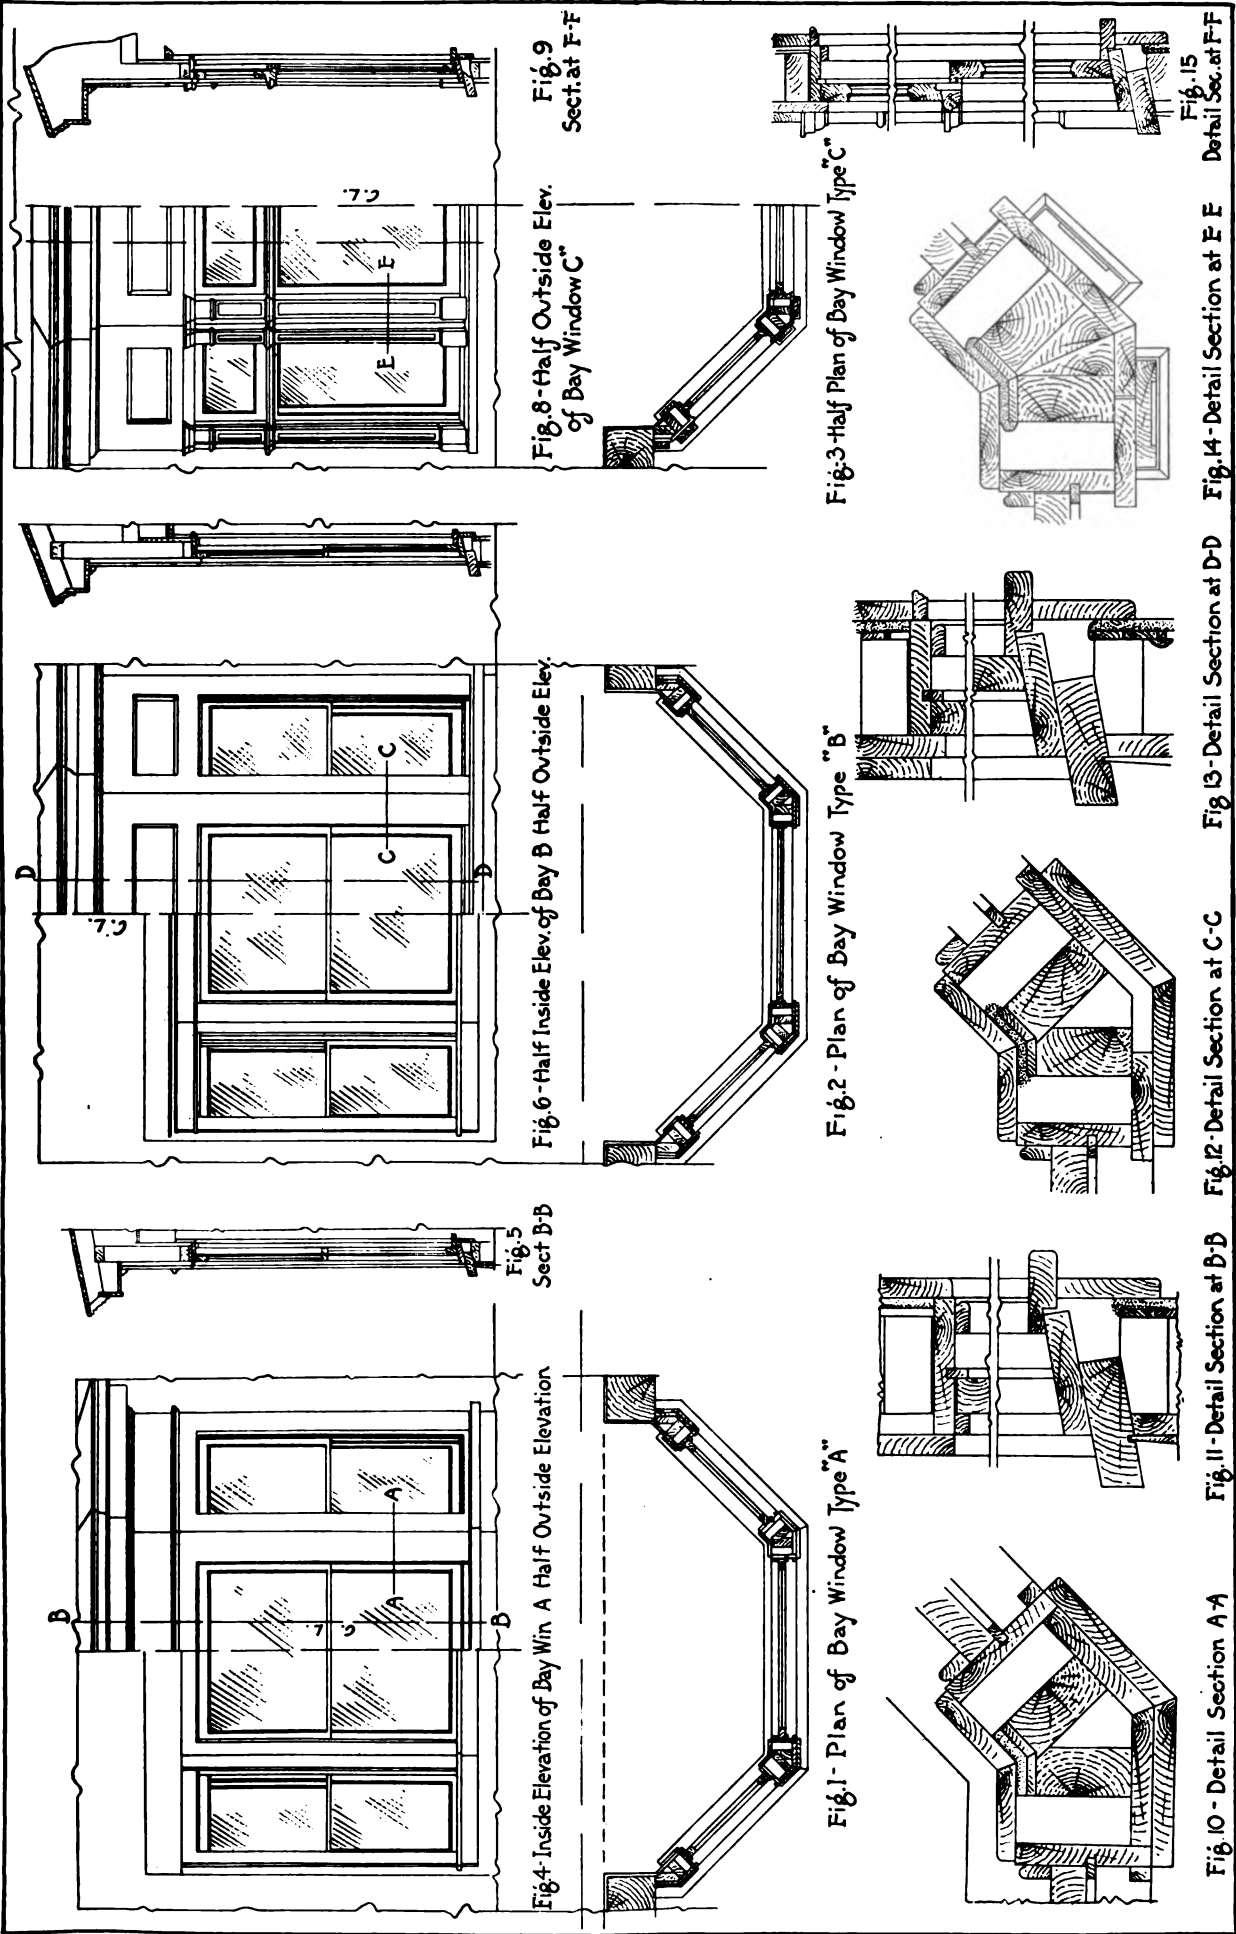

studs have been used sheathed on the outside with ⅞-in. boards. The frame would be made in skeleton at the mill without any outside casing, the latter being measured up after the frames are placed in position. Figs. 10 and 11 show in detail how the frames are built and the method of trimming them.

Fig. 2 is a plan of the same kind of a window as shown in Fig. 1, except the treatment of the frames is different. Where, as in Fig. 1, sheathing is placed on the studs there is none used in the window indicated in Fig. 2. Here the frames are provided with ⅞ x 3¾-in. outside casing at the studs and ⅞ x 5¾-in. heads. Afterward when the frames are in position on the job the millman measures up for the other necessary trim to complete the bay window. Fig. 6 shows a half inside and a half outside elevation; Fig. 7 a full length section through the window on the line D-D, while Figs. 12 and 13 represent the sections in larger detail.

In Figs. 3 and 8 are shown plan and elevation of the same style window but on a rather more elaborate scale. The frames involve a somewhat different construction, and the general treatment is clearly indicated in Figs. 9, 14 and 15.

The frames for this bay window also have a ⅞ x 3¾-in. outside casing and the same size of head. The corners are treated with beveled casings, as shown in Fig. 14, which is a detail of Fig. 8 on the line E-E. The pilasters have been added and in addition to being ornamental they also serve to close up the joints of the casings. Fig. 8 shows the outside appearance of the bay, the inside treatment being the same as that indicated in Fig. 6.

It is hoped that with the aid of the sketches the different schemes will be rendered perfectly clear to the reader. No doubt other methods of making bay window frames prevail in different localities, but the writer is of the opinion that the ones here represented are very extensively used.

Details of Bay Window Construction—Various Types

A Frame Cottage for the Suburbs

A Well Arranged House with Six Rooms and Bath—Shingled Walls and Roof

THE subject of our colored supplemental plate this month is an attractive story and a half cottage with field stone foundations and shingled walls and roof. Noticeable features of the exterior are the dormer window section which breaks the broad sloping roof, the unique entrance effect and the pergola which extends in front of the living room.

An examination of the floor plans shows the interior space to be divided into six rooms and bath. The feature of the main floor is the living room, which extends the full depth of the cottage and has at the end an open fireplace with face and hearth to be laid with chrome orange unglazed tile in 8 x 6 in. squares. This open fireplace is served by an outside chimney built of field stone and having bluestone cap 5 in. thick. The flues are 8 x 12 in. and lined with tile.

Main Hall and Stairs

The main hall and stairs occupy a section through the central portion of the house, the flight to the cellar being directly under that leading to the second story.

At the left of the hall is the dining room, beyond which is a commodious pantry which communicates with the kitchen, the latter occupying a wing or extension at the extreme left of the building. The pantry is well equipped with cupboards, drawers, bins, etc., and the sink is placed directly under a double window in the rear wall. The arrangement is also such as to give direct communication between the pantry and front hall, and avoids the necessity of passing through any of the principal rooms in going from the kitchen to the front entrance door.

On the second floor are three sleeping rooms, one of which extends the full depth of the house, directly over the living room. Features of this room are the seat at the rear wall under the window, and the three large clothes closets. The bathroom is at the front of the house and the hall space is reduced to a minimum. An idea of the internal arrangement at this point may be gathered from an inspection of the detail on another page which represents a vertical cross section of the building taken on a line running through the stairs and bathroom.

Foundations

The foundation walls are to be 16 in. thick with joints well pointed on all exposed masonry. The footing courses are to project 6 in. on each side of the field stone foundation walls and are to be 10 in. thick.

The main walls of the cottage are to be of wood construction, the outside studs to be covered with 1-in. tongued and grooved North Carolina pine boards laid diagonally. Over this is to be placed a layer of heavy building paper and this in turn covered with shingles, although stucco on metal lath can be substituted if preferred. The rafters are to be covered with sheathing boards upon which are to be placed cedar or asbestos shingles, according to preference, laid in regular courses with 5½ in. exposure to the weather. The shingles are to be fastened with galvanized iron nails.

Kinds of Wood to Be Used

All floor beams, plates, girders, etc., are to be spruce or hemlock, according to the preference of the owner, and all exposed woodwork is to be of first quality white pine or cypress.

The finish of the interior trim on the first floor with the exception of the kitchen and the pantry is to be chestnut. The trim of the kitchen and pantry is to be North Carolina pine. The trim of the entire attic floor is to be of basswood and the doors are to be of birch.

The entrance door is to be 2 in. thick, veneered with quartered oak on white pine core, and be glazed with polished plate glass, six lights and one panel, as shown in the detail. The pantry doors are to be double acting.

The leaders, gutters, roof flashing, etc., are to be of best quality tin painted on both sides before installing. Step flashings are to be set into the chimneys at the rake of the roof to insure against leaking.

The Plastering

The plastering is to be three-coat-work and the living room, hall and dining room are to have a sand finish. All other rooms on the first and second floors are to have a hard white finish.

The bathroom is to have porcelain enameled iron fixtures and the bathroom floor is to be finished in white tile on a bed of cement cinders. It is to have sanitary cove, wainscot and cap. It is also to be fitted with a medicine closet.

The kitchen and pantry sinks are also to be of porcelain enameled iron of standard make properly fitted and set. The soil pipe is to be 4 in. in diameter and the vents 3 in., all of cast iron. The house is to be piped for gas and wired for electricity, with combination fixture outlets in all rooms and hallway, also outlet in cellar and at the front entrance.

The heating is to be by means of hot air, the furnace to be of such capacity as to furnish a temperature of 70 deg. within when it is zero outside. The top of the heater is to be at least 24 in. below the finished ceiling. Side wall registers are to be used in every room except the kitchen and pantry,

Plans and Elevations of the Frame Cottage for the Suburbs Shown on the Supplemental Plate

Miscellaneous Constructive Details of Frame Cottage for the Suburbs Shown on Supplemental Plate

and they are to have a neat lattice grill with regulator.

All hardware in the bathroom is to be nickel-plated and throughout the remainder of the house the ornamental hardware is to be a dull brown finish.

All exterior woodwork, except the shingles, is to have three coats of white paint, ground in pure linseed oil. The roof shingles are to be stained a dark blue-green before laying. If asbestos shingles are to be used, they are to be of the same shade. The shingles on the exterior walls are to be white in finish.

All interior trim is to have two coats of varnish and to be stained dark brown with a wax finish.

According to the estimate of the architect, the cottage here shown has a cubic content of 24,293 cu. ft., upon which he places a unit price of 20c. per cubic foot. This estimate, he states, does not include a contractor's profit, nor does it cover any particular section of the country.

The design here illustrated and described was prepared by Architect Frank T. Fellner, 413 Caton Avenue, Brooklyn, New York, or care THE BUILDING AGE, 239 West Thirty-ninth Street, New York City.

Woodwork in Wall Board Interiors

Various Woods Available for Trim—Paneling Effects—Moldings—Numerous Examples Illustrated

BY JOSEPH A. POESL

AS an interior finishing material, wood is hardly equaled. There is something about it which imparts an atmosphere of life and health. It is beautiful and friendly. With it comes a human sentiment unequaled by any other mate-

a room calls for not alone the use of the usual wood trim found in practically every room, but for paneling strips, picture molding, plate rail, wainscot cap, chair rail, and other decorative woodwork. Thus the increased use of wood for interiors is

Fig. 1—Various Styles of Paneling Strips

Fig. 2—Three Types of Picture Moldings

Fig. 3—Cross-Sections of Three Forms of Plate Rails

Woodwork in Wall Board Interiors

rial which we construct homes with for shelter, comfort and beauty. In fact, it creates an ideal expression of the home, and lends to that an expression of warmth, sweetness and hospitality.

A room finished with wall board offers more opportunities for the enjoyment of these desirable qualities of wood than does a plastered room. Such

encouraged, which is one of the reasons for the tremendous popularity of wall board.

Yet it must not be assumed that a wall board interior is, consequently, more expensive. The truth is, generally speaking, it figures about the same as one with lath-and-plaster walls in this respect. The fact that the former is always paneled with

wood strips is really an advantage, for, unquestionably, paneling is a most excellent means of decorating walls and of securing charming interiors at a low cost.

We are beginning to realize the superb effects obtainable by different treatments of wood and learning to apply the characteristic virtues of each variety to their best usage. The new and simple methods of treating wood now in vogue do not conceal but rather emphasize its beauties. Indeed, wall board is fortunate in that wood is its indispensable complement.

To-day, the tendency is much toward the use of soft woods for interior trim. As a result, cypress, California redwood, Douglas fir, yellow pine and white pine are in great demand. If, however, it is desired to use a hard wood, let us not overlook our native products. There is no need to pay high

to show the limitless possibilities for variety in paneling strips, a dozen different designs are illustrated. These have been selected haphazardly. They should not, therefore, be utilized without regard for other trim, and the greatest pains should be taken to have them match it. Paneling strips are never less than $\frac{3}{8}$ by $1\frac{7}{8}$ in. in size, and may be as large as $\frac{5}{8}$ or $\frac{7}{8}$ by 6 in.

Picture molding, like other decorative moldings, is not actually essential in a room covered with wall board, but it can be used to very good advantage instead of a paneling strip to conceal a horizontal joint, and at the same time to improve the appearance of the room. An important feature to remember in connection with picture molding is to have it always generous in size. Those stingy-looking picture moldings commonly seen have no decorative value whatever. Several typical picture

Woodwork in Wall Board Interiors

prices for imported woods when, for example, birch can be substituted for mahogany. Properly stained, it is such a perfect imitation that only experts can distinguish it from the other. It may be surprising to the layman to learn that natural mahogany is light in color, much like other woods, and only by copious staining does it reach its conventional color. Another American wood which closely resembles an expensive imported wood is red gum. It is hard to tell it apart from Circassian walnut. On account of its low price it is puzzling why it is not more popular with home builders.

Paneling strips, as shown in Fig. 1, are all-important in a wall board room. In themselves, they are capable of creating any style of interior decoration, or of accentuating the style that may be already existing. It follows, then, that it is well to exercise care to properly design and adapt them. As almost everybody is aware, they are placed over the joints formed by wall board panels. In order

moldings of good design appear in Fig. 2 of the illustration.

In dining rooms and dens, plate rail—Fig. 3—is particularly appropriate. It is customarily located about six feet from the floor. As is the case with all moldings in wall board construction, plate rail is a component part of the wall itself when placed over a panel joint—not a mere fastening. It is poor policy to buy such illy-designed plate rails as are sold by the average wall-paper dealer. They are generally a conglomeration of curves, and are ridiculously unfit for any room.

Then there are chair rails and wainscot caps, as shown in Fig. 4. The difference between the two is that chair rail is located on the wall at such a height as to protect it from the backs of chairs, while wainscot cap is located higher, at the division line between the wainscot, or dado, and frieze. Some chair rails might do for wainscot caps, but very seldom are wainscot caps used in place of

chair rails. Perhaps the moldings of these kinds shown will help to point out the distinction.

One of the most useful moldings in connection with wall board work is crown molding. Placed in the corner, at the conjunction of the wall and ceiling, it produces not only an attractive trim, but also does away with the two paneling strips which are ordinarily used in this corner. Thereby much labor is saved in addition to the enhanced appearance that results. There are many different crown moldings; only a few are shown in Fig. 5.

It will be observed that several other ways of treating ceiling corners are shown in Fig. 6. These are only interesting for their variety and to illustrate some methods of treatment without crown molding.

When an elaborate treatment for a ceiling corner is desired, a cornice is the solution. As will be seen in the illustration, Fig. 7, it is built up of several individual moldings. Cornices are used much for period decoration.

False beams, Fig. 8, are very often seen on wall board ceilings. They are not so very expensive,

Fig. 8—Showing Cross-Sections of False Beams

Fig. 9—Six Styles of Corner Moldings

Fig. 10—Showing Applications of Special Moldings

Woodwork in Wall Board Interiors

and give to a room a certain dignity which is difficult to secure otherwise. The flat beam shown is the most common, while the other is used considerably for high ceilings with narrow panels.

Corner molding is also handy in wall board construction. It will be noticed that a set of moldings of each style are shown in Fig. 9, each set comprising a molding for an exterior and for an interior corner. These are labor-saving in that they are quickly applied, much quicker than two paneling strips could be put on.

We have yet to mention those special moldings used at the baseboard and around the door and window casings when wall board is applied over plaster, or when it is used with door and window frames made for lath-and-plaster walls. Invariably, they are especially designed and made, although stock moldings might be suitable in some cases. In Fig 10 are shown their shape, as well as how they are used.

In conclusion, moldings, particularly paneling strips, are frequently employed for decorative effect, and are, therefore, not always placed over panel joints. In such event it is necessary to put headers between the studs and joists directly behind them so as to provide a solid nailing background to which they can be fastened, holding the molding and wall board together in close contact.

A Difficult House Moving Operation

The moving of buildings involving difficult features in their execution is always a subject of interest on the part of our readers, as is evidenced from the attention given to the articles which we have published in the past illustrating and describing jobs of this nature. One of the latest to which attention may be invited is that of moving what is known as the old Crocker residence near San Francisco, involving steep grades and sharp curves. The house is 85 x 135 ft. in plan, has six large chimneys, is four stories in height and of heavy construction, the weight being roughly estimated at about 800 tons.

In raising the building from its old foundations, five rows of 10 x 12-in. beams were placed lengthwise directly under the floor joists of the building. Under these longitudinal beams were placed 12 x 14-in. crossbeams spaced 3 ft. apart. One of the chimneys is estimated to have weighed 45 tons, and

under this extra beams were placed in order to carry the unusual weight.

Beneath and parallel to the crossbeams and resting in turn on two lines of 18 x 18-in. timbers running the full length of the building were short 14 x 16-in. spring beams. In this way, the load was finally centered on the two 18-in. beams which bore directly on the 8-in. rollers and to which was applied the "pull" for moving the structure along the runway. The drawing power was supplied by two two-horse teams on capstans operating 7-sheave tackles rove with 5/8-in. wire rope. The tackles were attached to a 2-in. cable fastened to the 18-in. beams in such a way as to equalize the strain and prevent a greater pull coming on one tackle than on the other. The dead end of the hauling rig was secured by digging a 10-ft. trench 30 ft. long. This trench was bulkheaded with 8 x 10-in. timbers and in it were placed four upright posts 14 x 14 in. in cross section and 10 ft. long. A 2-in. cable was

wrapped around these posts and then led to a convenient point for attaching the tackle.

In carrying out the operation, a trestle 300 ft. long had to be built across a ravine and with a 500-ft. grade down which the house must descend at the rate of $1\frac{1}{2}$ in. per ft. The contractor agreed to move the house without injuring the trees on the estate and in order to do this the house had to make some sharp curves in its journey. In one case a right-angle turn had to be made in about 400 ft. to avoid cutting the trees. A runway of house-movers' cribs was built ahead of the structure as it advanced. The rollers ran on a bed of 12 x 14-in. stringers resting directly on the cribs, and where the runway was highest the cribs were held in place with 12 x 12-in. braces every 20 ft.

Just before descending the steep grade it was necessary to swing the house through a half turn. This was done by building eight circular runways beneath the shoring and providing each with rollers. When this turntable, so to speak, was ready, the "pull" was applied at opposite corners in opposite directions, and by changing the direction of "pull" from time to time, the half revolution was successfully completed.

The house-moving contractor who superintended the work was Ellis Anderson of Burlingame, Cal.

Tenement House Construction in New York City

The cost of material and conditions in the labor market are reflected in the report of the Tenement House Department just issued which shows that though there was a decrease of nearly 33 per cent in the number of houses planned during the second quarter of 1916 in Greater New York, the cost of constructing them is \$4,413,600 greater than for the larger number last year.

During the quarter in question 30 plans were filed for new tenement houses estimated to cost \$24,805,500, as compared with \$20,481,900 for the corresponding period of last year.

A remarkable increase appears in the valuation of tenements planned in Manhattan during this quarter as compared with the same quarter last year. During the quarter ending June 30 there were tenements planned to cost \$18,761,000, while for the same period last year those planned were valued at \$5,512,000. While it may be said that many of the plans were filed to forestall the operations of the zoning and heights resolution it is probable most of them will be built, although delay in starting many of these operations may be due to the cost of materials and scarcity of labor.

The value of tenements planned during the second quarter for the Borough of the Bronx is \$3,633,000, while for the same period last year the cost was \$7,089,500.

In Brooklyn during the period covered by this report tenements to the value of \$3,537,500 were planned, while the corresponding figure for last year was \$6,272,400.

The figures for the Borough of Queens for the same periods of the two years are respectively \$874,000 and \$1,620,500.

The number of tenements planned during the quarter for the whole city is 433. Eighty-eight of

these were proposed for the Borough of Manhattan, 70 for the Borough of the Bronx, 167 for the Borough of Brooklyn and 88 for the Borough of Queens.

Last year during the same quarter 645 tenements were planned, 63 of which were for Manhattan, 158 for the Bronx, 268 for Brooklyn, 148 for Queens and 8 for the Borough of Richmond.

There are now in the city 104,244 tenement houses; of these, 77,743 are old law tenement houses and 26,502 have been erected under the modern law. There are now 6304 more tenement houses in the Borough of Brooklyn than in Manhattan. In the Borough of Brooklyn there are 47,202 tenement houses, while in the Borough of Manhattan there are 40,898. The number of apartments in Manhattan, however, is much greater than that in Brooklyn, there being 536,647 apartments in the former and 268,677 in the latter. The number of apartments in the whole city is 964,986.

Sheet Metal Contractors' Committees

President George Harms of the National Association of Sheet Metal Contractors recently appointed committees to have charge of various phases of the work of the association during the ensuing year, the chairman of each being as follows:

Warm-air Furnace—J. H. Hussie, 2407 Cuming Street, Omaha, Neb.

Apprenticeship—O. E. Cluss, 2408 South Jefferson Avenue, St. Louis, Mo.

Legislation—F. W. Stechow, 904 Central Avenue, Cincinnati, Ohio.

Trade Relations and Policy—E. L. Seabrook, 261 South Fourth Street, Philadelphia, Pa.

Fire Prevention—Fred de Connigh, 930 West Nineteenth Place, Chicago, Ill.

Overhead Expense—Louis Luckhardt, 508 Second Avenue, Pittsburgh, Pa.

Advisory—J. D. Riley, 2625 Sarah Street, Pittsburgh, Pa.

Trade Development—E. B. Langenberg, 4045 Forest Park Boulevard, St. Louis, Mo.

Lecture—F. B. Hiller, 3105 Detroit Avenue, Cleveland, Ohio.

San Francisco Labor Situation

Our San Francisco correspondent, writing under date of Aug. 5, says: "With the settlement of the waterfront strike late in July, and the resumption of work in the lumber yards on an 'open shop' basis, lumber began pouring in from the northern ports, and the local retail yards have had quite a rush. Construction had been postponed or retarded on many buildings throughout the city, and with plenty of material the work is now being hastened.

"Work on Class 'A' buildings is being retarded somewhat by a strike of structural steel workers. The Building Trades Employers' Association recently notified the Building Trades Council that the places vacated by the strikers would be filled at once under 'open shop' conditions, this action being endorsed by the Law and Order Committee of the Chamber of Commerce."

Some Aspects of Modern Shingling*

Various Methods of Treating the Hips— What Is Known as the "Boston Hip"

EDWARD H. CRUSSELL

FOR covering the hips on shingle roofs many different methods have been devised, some appearing to be native to certain localities. Perhaps the most primitive method is that in which the hip is covered with two boards in the same

circular section, recessed or rabbeted to fit the hip, as shown in Fig. 29.

Some builders prefer to cover the joint at the hip with metal shingles. This makes a weather-proof job, but is not acceptable to all tastes. Orna-

Fig. 28—View of the Hip Boards

Fig. 29—Perspective of a Hip Roll

Fig. 31—Form for Bending Metal Hip Shingles

Fig. 30—Showing Metal Hip Shingles in Place

Some Aspects of Modern Shingling

manner as usually adopted for the ridge. The courses are carried out to the hip and cut off without any particular care; then, after the shingling is finished, the hip boards are jointed and fastened in place over them, a lapped joint being used in preference to a mitered one as shown in Fig. 28.

Sometimes the hip is covered with a molding instead of boards. The molding is generally of

mented hip shingles can be purchased for this purpose, or a simple strip of tin or galvanized iron may be used. Perhaps the most simple form of home-made metal hip shingle consists of a strip of tin about 4 in. wide, long enough to extend two or more inches under the following course and with its lower end cut to a semicircle. This style of hip shingle is shown in place in Fig. 30.

Instead of cutting the lower corners of these

*Copyrighted, 1916, by Edward H. Crussell.

metal shingles, they are sometimes turned under in such a manner that they fit around the lower ends of the shingles on which they are placed and are held down by them. The easiest way to bend the shingle is over a form like Fig. 31. This is nothing more than a piece of shingle of the correct width and shape, fastened to the edge of the work bench or some other convenient place. The reverse side of the tin shingle is shown at A in Fig. 31. It is easily made and the turned corners, when slipped into place, obviate the necessity of nailing the lower end of it.

Another early method of covering hips was what has been called "weaving" them. This method requires that both sides of the hip be carried up at the same time. It is illustrated in Fig. 32. The course of shingles on one side of the roof is finished out and fitted to the hip by paring the edge.

marking the shingles and they are cut with a hand-saw, six or eight being held together and cut at the one time.

Sometimes, to avoid so much short grain, the bevel required at the hip is divided between two or more shingles, which makes a great deal more work but leaves the shingles in better condition. The writer has heard this described as the "fantail" method. It is illustrated in Fig. 34. These shingles, also, are cut to pattern, and perhaps the best arrangement is to "turn the hip" with five shingles, two on one side and three on the other, reversing the order for each course. A pattern is, of course, needed for each different shape of shingle, and to avoid confusion it is better to number the shingles as they are cut.

The hips may be shingled a little in advance of the plain shingling in the same way that a brick-

Fig. 32—Showing What is Called "Weaving" the Hip

Fig. 34—Appearance of the "Fantail" Hip

Fig. 33—Hip Shingles Running Parallel with Hip

Fig. 35—Style of Hip Suitable for Steep Pitch

Some Aspects of Modern Shingling—Showing Various Styles of Hip Treatment

The last shingle of the corresponding course on the other side is then carefully pared and fitted over it. In the next course following, this procedure is reversed, so that the center joints of the shingles show a broken line up the hip.

The lower corners of these shingles require nailing and the nailing must be done carefully, as they are easily broken. Indeed, the ends of these shingles often curl up and split off from the effects of sun and weather after the roof is finished, which has led to a change in methods of cutting the hip shingle.

One method is to lay the hip shingle parallel with the hip (instead of perpendicular to the eaves) and trim it to shape from the bottom and inner edge, as shown in Fig. 33. This leaves the short grain of the shingle on the inner lower corner, where it is not so liable to damage. A pattern is used for

layer builds a corner, or they may be carried up with the plain shingling, which necessitates all four sides of the roof being carried up at the same time.

Weaved* hips may also be laid after the plain shingling has all been finished, although the writer has heard the possibility of this denied. It is much the best method of the three as it allows any side of the roof to be shingled separately. It is accomplished by leaving one or more shingles off the ends of the courses; then, after the plain shingling is finished, the hip is carried up by piecing out the courses on each side of it. Of course, care must be exercised to have the courses from each side of the roof match at the hip, and perhaps this is as good a place as any to point out that on roofs of unequal pitch it will be necessary to vary the width

*Woven hips may be the correct term but the writer has never heard it used.

of the courses on one side or the other in order to have them do so.

A method of shingling hips that used at one time to be very popular in certain sections is shown in Fig. 35. In this method the hip shingle, instead of being cut to a point, is allowed to run down to the course below, which does away with the short grain and the tendency to split.

The writer feels that Fig. 35 may not be as clear

Fig. 37—Method of Fitting the "Boston Hip"

Fig. 38—Lower Courses of Hip Trimmed Ready for Shingling

to the novice as he would like to have it, and it may help some to mention that the shingles A and B of this figure both belong to the same course, and are in the same plane. If the lower end of shingle A was cut off to line with course B, then course B would be the same as any course in Fig. 32, excepting that the outside shingle would be slightly thinner than the others. Perhaps the easiest way to understand Fig. 35 would be to look at Fig. 32 and imagine the last shingle in each course extending down to the course below it.

This method seems better suited to steep roofs than those of low pitch, and the appearance of the finished hip, though rather unusual, is not displeasing. The hip shingles must all be of the same width and should be of such a width as to cover the diagonal line of the hip from one course to the other, as shown in the drawing. If for any reason shingles of this width are not obtainable, two shingles may be used, each one-half of the required width, and a variation of the design may be obtained by placing the inner shingle so that it extends only half-way down the course below. This I think may be understood without the aid of a separate drawing. The center line of joints of this hip are broken, as in Fig. 32, and the lower ends of the shingles must be nailed.

We will close this chapter on hips by a description of the "Boston hip," pictured in Fig. 36, which is perhaps the most popular style of all.

There are some variations of this hip, the easiest one to apply being that in which the plain shingling is carried out to the corner of the hip and the hip shingles are then laid over it in the same manner

as already explained for laying a shingled ridge. This is not a true Boston hip and is more properly termed shingled hip.

The correct method of laying the Boston hip is shown in Fig. 37, where it may be seen that the upper end of the hip shingle is cut to fit against the side of the plain shingle in the course above (as shown at A) instead of being laid over it. This gives a much neater appearance to the finished hip, which is of some importance in first-class work or in work that is close enough to the ground to be easily examined.

The writer's method of laying this hip differs considerably from that usually advocated, but it is the one he has found to be the quickest and easiest. Do the plain shingling first, stopping the courses about 4 or 5 in. from the center of the hip, but making no effort to get them exact. The double course at the eaves should be fitted as carefully as if no shingles were to be laid over it. After the plain shingling is finished, snap a chalk line down each side of the hip at the width you have decided upon for the hip shingle. This is usually 4 in., though it may vary from 2 to 5 in., according to circumstances, the wide shingle being used as a large

plain roof and the narrow one on such work as the hips of a small tower or octagonal summer house.

The writer is of the opinion that the appearance of the hip is improved, especially where wide shingles are used, by tapering the width of the hip shingles so as to make them smaller at the top. The tapered hip involves no extra work, and is worthy of trial.

Fig. 38 shows one side of the hip as it appears after the line for the hip shingle has been struck. The first move is

Fig. 36—Appearance of the "Boston Hip" on a Roof

Fig. 39—Showing the Beginning of "Boston Hip"

Fig. 40—"Boston Hip" with Beveled Shingles

Some Aspects of Modern Shingling

to piece out, or trim back, the ends of the plain courses so as to bring their lower corners to the line. The trimming is best accomplished with the aid of a long paring chisel about 1½ in. wide, and has already been done on the first three courses of Fig. 38. Where the plain shingling does not extend to the line, as at A, a narrow shingle must be laid to fill out, and sometimes it is necessary

to split a piece off the shingle already laid in order to have the narrow shingle of a reasonable width. Only those courses are trimmed that can be reached without moving.

The shingles to be used for covering the hip must, of course, be wide enough, but do not need to be of the exact width. The first hip shingle laid must be cut on the lower edge to coincide with the edge of the roof as may be seen in the photo, Fig. 36. After the lower edge has been cut the shingle is laid to the line and fastened in place with a couple of nails, its upper end extending over the course against which it is to fit, as shown in Fig. 39.

The upper end is now trimmed off with the chisel at the dotted line and two more nails are driven in where they will be covered by the following shingle. The shingle now being firmly nailed, its outer edge is trimmed to the bevel of the hip, after which the shingle on the other side is laid and fitted in the same manner. The joints up the center of the hip should be broken, as in Fig. 32, and to achieve this the first shingle in the second course must be laid on the far side of the hip, or immediately following the shingle just laid. This laying of two shingles in succession on each side of the hip is sometimes a little puzzling to the novice, but he soon sees the reason for it.

One variation of the Boston hip is that in which all the hip shingles are beveled on the lower edge so as to line up with the plain shingling, as in Fig. 40. This entails a lot more work, but the idea is sometimes of use in ornamental shingling where something special is required. Another method is to cut the hip shingle to fit against the *second*, instead of the *first*, course above. This is useful where the roof is steep and the shingling is laid with narrow exposure to the weather, in which case the hip shingle, if cut as in Fig. 37, will be too short to make a satisfactory job.

(To be continued)

Hydrated Lime Plaster

The use of hydrated lime plaster for scratch and brown coats is gradually growing in favor with architects and builders. Up to 15 or 20 years ago, it will be recalled by some of the older contractors, that when any interior plastering was to be done, use was always made of lump lime, sand and hair. In those days it was necessary to slake the lime after it was delivered on the job. This operation of slaking often required several days to complete, and was looked upon as inconvenient.

Hydrated lime plaster, has, however, been in the market for several years, and gives all the advantages in finished walls of old-fashioned lump lime, but eliminates the inconvenience, for hydrated lime is delivered on the job slaked all ready for the addition of sand and can be mixed and applied with the same convenience as other plaster in the market to-day.

Another point in favor of hydrated lime plaster is that it is a nonconductor of sound. Acoustical experts are agreed that old-fashioned lime plaster and lath was the best nonconductor of sound, and as hydrated lime plaster gives the same good results that were formerly accomplished with lump lime, architects and builders are quick to grasp the

value of this material for residences, churches, school buildings, hospitals and all other buildings where quiet conditions are desirable or good acoustics are essential.

The advantages to be gained by the use of this material warrant the consideration of all builders, as its real value can be determined by the increase in tonnage.

Value of Brick and Tile Products

The value of the brick and tile products of the United States in 1915, according to the United States Geological Survey, was \$125,794,844. Three varieties of brick and tile and miscellaneous products increased in value in 1915 compared with 1914. Front brick, valued at \$9,535,536, increased \$245,913, or nearly 3 per cent over 1914; drain tile, valued at \$8,879,264, increased \$357,225, or 4 per cent; fire brick, valued at \$18,839,931, increased \$2,412,384, or nearly 15 per cent; and miscellaneous products, valued at \$3,716,944, increased \$551,130, or 17 per cent. There was a decrease of the total product of about 3 per cent.

The product that showed the greatest decline was sewer pipe. Common brick and terra cotta also showed decrease compared with 1914. The decrease in these industries occurred during the early months of the year, but the conditions improved during the last three or four months of the year, the year closing with bright prospects for 1916.

Another Mammoth Apartment House

Plans have recently been filed with the Bureau of Buildings for the borough of Manhattan, New York, for another notable addition to the group of artistic structures to be erected in the vicinity of the Grand Central Terminal. According to the plans, the project is to be carried on by the New York Central Railroad, and the structure will cover the entire block bounded by Forty-eighth and Forty-ninth Streets and Lexington and Park Avenues. It will be twelve stories in height and cost \$2,500,000. The site measures 405 ft. on each street and 200.1 ft. on each of the avenues.

When completed it will be the largest apartment house in the city, covering an area of over 32 lots, or more than two acres of ground. The present largest apartment house is the Belnord, which covers 17 city lots. The new structure has been designed by Whitney Warren and Charles D. Wetmore, who planned the new Grand Central, as well as all of the buildings in that zone controlled by the railroad company.

Condition of the Building Industry

According to the report of the Chamber of Commerce of the United States, issued on Aug. 13, the building industry is stated to be in generally excellent shape. It is, in the opinion of the committee, the best barometer of general business, since building in the country districts means the extensive use of materials in almost every line of commercial business. Despite the high prices of material, the committee report concludes, the building outlook continues good.

Trade Topics—Every Reader is Invited to Participate

Rules for Finding Lengths and Bevels of Rafters and Braces

From D. W. Daley, Parkersburg, W. Va.—I noticed in the July issue of *THE BUILDING AGE* a table by W. S. Wilkin for finding the lengths of common rafters, and I am sending herewith some figures which I used many years ago. While working as a draughtsman in a steel plant, I used the table here given for the purpose of obtaining the lengths of braces, etc. A portion of the information is copied from "Kidder" and a part of it is copied from "Ellis." I am sending the sketches, table, etc., as I feel sure the information will be useful to many readers of the paper.

Referring to the diagrams, the lines AB and BC

Fig. 1—One Method of Finding Lengths and Bevels of Rafters; also Method of Backing a Hip Rafter

Rules for Finding Lengths and Bevels of Rafters and Braces

in Fig. 1 represent the walls at the angles of a building; BE is the seat of the hip-rafter, and GF of a jack-rafter. Draw EH at right angles to BE , and make it equal to the rise of the roof; join B and H and HB will be the length of the hip-rafter. Through E draw DI at right angles to BC . Upon B with the radius BH describe the arc HI , cutting DI in the point I . Join B and I , and extend GF to meet BI in J ; then GJ will be the length of the jack-rafter. The length of each jack is found in the same way—by extending its seat to cut the line BI .

From F draw FK at right angles to FG ; also FL at right angles to BE . Make FK equal to FL by the arc LK or make GK equal to GJ by the arc JK ; then

the angle at J will be the top bevel of the jack-rafters and the one at K the down bevel.

Now in backing a hip-rafter, proceed as follows: At any convenient place on BE , as O in Fig. 1, draw the line MN at right angles to BE . From O describe a circle tangent to BH , cutting BE in the joint S . Join M and S ; also N and S , then these lines will form at S the proper angle for beveling the top of the hip-rafter.

A second method for finding the lengths of jack-rafters may be described as follows: Lay the rafters side by side and square over a line at one end as at $A-A'$ of Fig. 2. Then from $A'-B'$ either snap a chalk line or draw a line with a straight-edge. Where this line cuts the face of each rafter, is its

Fig. 3—Showing Seats of Hip and Valley Rafters in Roofs of Different Pitch

length on the longest side. Now having found the bevel as described in method No. 1, apply the bevel to the edge of each rafter and mark the bevel cuts as shown in Fig. 2. In the case of end jacks in irregular roofs, mark the bottom ends to the same angle as the roof is in plan instead of "square," as shown in diagram and measure the length of the common rafter up from this point.

For each 2 ft. the building is wide, the seats of hip and valley rafters is 1 ft. 4 $\frac{31}{32}$ in., as shown in Fig. 3, which measurement use for the run and the same rise used on the common rafters. The same number of runs will give the length required. This is for intersections of equal pitches.

The table referred to in the early part of my comments is presented herewith, the figures being such as to meet all the stated requirements.

Rise or Run in Feet	Rise or Run in Inches	Rake in Feet and Inches of Common Rafters	Rake in Feet and Inches of Hip and Valley Rafters
The Rise and Run May be Reversed		Length of Common Rafters for Each 1 Ft. of Run	Length of H. & V. Rafters for Each 1 Ft. of Run
1 ft.	1 in.	1 ft. 0 5/128 in.	1 ft. 0 5/256 in.
1 ft.	2 in.	1 ft. 0 21/128 in.	1 ft. 0 5/64 in.

1 ft.	24 in.	2 ft. 2 13/16 in.	1 ft. 8 49/64 in.

Trouble With Glued-up Work

From W. M. D., Baltimore, Md.—I noticed in one of the back numbers of THE BUILDING AGE that a correspondent had trouble with work which he had glued up. He asked why the work was not straight after the clamps were removed, as he had jointed and fitted it perfectly straight before gluing.

For his benefit and that of the readers of the paper who have not had much experience in this line, I will endeavor to explain the difficulty. The trouble occurs mostly in gluing up such work as table tops and the like, where the clamps are opened out 3 ft. or 4 ft. or more, with 3 or 4 joints. I am presuming that iron clamps are used by the majority of carpenters, and if they will take the trouble to lay three or four 12-in. boards on a couple of trestles, put on two or three clamps and tighten them up, it will be found that the backs of the clamps have bowed down and the boards have followed the shape of the clamps as a consequence. If the work is glued up in that shape it will remain so when the glue has dried and the clamps have been removed.

My remedy is to use two sets of clamps—one set on the top and one set on the bottom. First put on the top clamps and draw the work together, then lay a straight-edge across the work which will invariably be bowed up; after this has been done, put on the bottom clamps. Tighten them up and loosen up the top ones until the straight-edge and the work come in line. See to it that all the clamps are tight and the work straight across, then when the glue is dry and the clamps are removed, the work will be straight.

In jointing up such work it is necessary to make the joints fit to a hair from end to end. The first piece should be jointed straight and square on the edge; the piece that is near to it should be fitted by a straight edge across both pieces, regardless of the square.

I usually dowel the joints, placing the dowels

about 18 in. apart. The dowels should have a small groove or saw kerf the full length of the dowels in order to let out the air. If one of them becomes air-bound no power will drive it in, so precaution is necessary.

In concluding, I would say that the glue used should be comparatively thin. The draught should be shut out of the shop and the gluing should be done in a hurry.

Shingling Staging

From D. P. Barry, Redford, N. Y.—In looking over the comments in regard to shingling on the Pacific Coast from "G. L. McMurphy," and which appeared in a recent issue of the paper, I am constrained to give a description of what I regard as the simplest and quickest made shingling staging. I shingle to two or three lines, and there are no shingles that do not need trimming. It is of no consequence that the butts are somewhat uneven; often a lot of trimming is needed to get the butts approximately in line.

A straight-edge is out of the question on a building 40 to 200 ft. long—a straight-edge keeps the shingler moving too much. Two good shinglers on a plain roof with good shingles will lay 8000 to 10,000 shingles in a day, but 2500 to 3000 shingles are all anyone should aim to lay. There is no reason, to my mind, why the carpenters' trade should be singled out for rapid transit work. It is nerve racking any way you take it.

Discussion of Building Methods

From J. P. W. Lane, Kans.—In looking over the July issue of THE BUILDING AGE I notice D. P. Barry of Redford, N. Y., gives me quite a send-off in regard to the construction of a box sill which I described some time ago. Now, if I had been in the correspondent's place I fear I should not have made any mention of his sill No. 1 with the 2 x 4 on the sides for the joists to rest upon where most of the weight comes. His No. 3 is not much better; in fact in some respects it is worse to my way of thinking because doubling the 2 x 8-in. flat on the wall will cause them to rot out much sooner than if single and can be no better than if single for strength if laid on a solid wall. Again the 2 x 8 in. he cuts up to which to nail them does not touch the studs if 2 x 4 in. are used. We use cross bridging to keep the joist from twisting.

His No. 4 solid sill is all right, but it will rot sooner than the sill shown in my sketches and is not any stronger after he has filled it full of holes. Another thing, he cannot fasten his studs as securely if he simply toe-nails them on top, and the cost of labor is at least ten times as large with nothing gained.

In regard to his sills I have talked with two builders of established reputation in the trade and their opinion is much the same as mine. I do not profess to know it all, but I have a boy whom I taught to be a carpenter. He is now a foreman and working on buildings that involve an expenditure running up into big figures. He draws, I expect, as big a check weekly as the correspondent in question, and he was born and raised in Lane, Kan.

In regard to squares a 16-in. tongue is good

enough for me or for anyone if he knows how to use it. I have owned a 16-in., a 17-in. and an 18-in., but it so happens now that I have only three squares and they all have 18-in. tongues. My boy took my 16-in. tongue with him when he left home.

I am inclined to doubt if the correspondent ever put on laths diagonally or he would not say there was no sense wasting time lathing that way. In my judgment, it takes no more time and every scrap of lath can be used. I would prefer boxing inside and out if it were the same price but how many people will pay for it except in a cold climate. Lathing diagonally on boxing put on horizontally makes the best job of plastering of which I have knowledge and that is the reason I prefer it on the inside.

I would say that I am not greatly impressed

shelf, which is 4 in. deep by 69 in. long inside, accommodates 18 fruit jars set in a single row. Six of these shelves are built into the closet and every jar of fruit is visible when the doors are opened. If it is customary to use pint or two quart jars, the shelves should be built accordingly. Shelves for two-quart jars should be 5 in. deep with a space of 10 in. between the shelves. Pint jars require only 6 in. between the shelves, while 8 in. is required for quart jars. The two bins at the bottom provide space for potatoes or other vegetables and also gives to the closet a wide base to prevent any possibility of tipping. It is unnecessary to build a bottom in these bins if the closet stands on a good floor.

The front of the fruit jar shelves is closed by

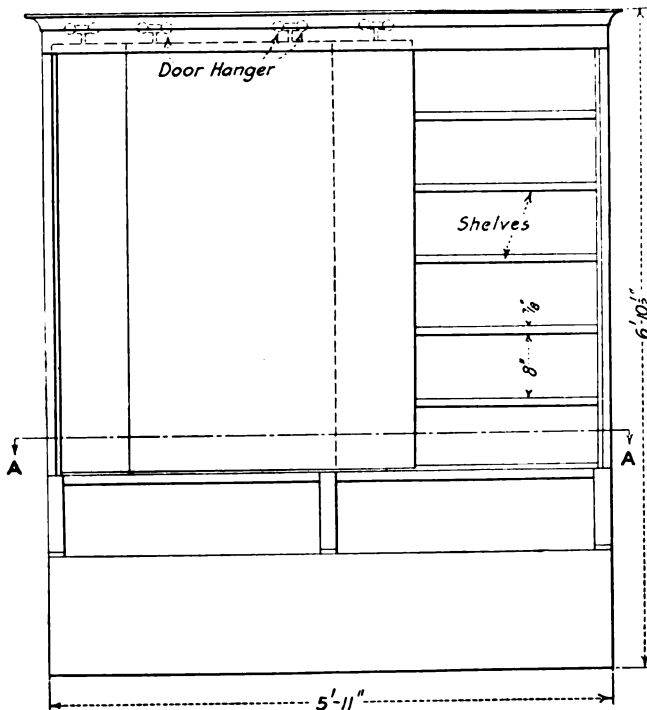

Fig. 1—Front Elevation of the Closet with Door Pushed to One Side Showing the Shelves

Details of a Fruit Closet—By E. J. G. Phillips

with the correspondent's sill and threshold combined, because when it becomes worn it will require too much work to renew it.

Details of a Fruit Closet

From E. J. G. Phillips, Aurora, Ill.—A fruit closet in which every jar is in sight, is the ideal way to store the winter's supply. This can be easily accomplished without taking up any more space than the ordinary shelves, by building a closet like that shown in Fig. 1 of the illustrations. If made to the dimensions given, it will have a capacity of 108 quart fruit jars. Each

two sliding doors. These doors slide in parallel tracks attached to the top board of the closet as shown in Fig. 5. Door No. 1 slides in the outside track and door two slides in the inside track. A fascia strip in front of the tracks extends down below the top of the doors closing the top tightly. Fig. 2 shows plainly the details of construction. The doors may be very simply constructed by using one thickness on 5/8-in. beaded ceiling held together by a strip across the top and bottom. Braces such as would be necessary in a hinged door are not required in the sliding door. They are hung from the top and therefore are not subject to sagging or such strains as would be produced in a door hung from the sides. A narrow

strip attached to each side vertically between the top and bottom strips will fill out the thickness of the doors where they overlap at the center and close this space tightly. The hanger shown in Fig. 4 is of small size built especially for very light doors. It rolls in a track $1\frac{3}{8}$ in. wide by $1\frac{1}{4}$ in. high.

If this closet is built of yellow pine and given a natural finish, it will be quite as pleasing in appearance as it is useful.

Elevation for Ten Room Twin House

From T. T. Carter, Bluefield, W. Va.—I am sending a sketch representing a front elevation of the ten-room twin houses concerning which the corre-

Elevation for Ten-Room Twin House

spondent made inquiry in a late issue of the paper. This front has been satisfactorily built here in brick, stucco and in concrete blocks. The space mentioned by the correspondent above the doors for the windows could be evenly divided and doors with glass panels with transoms would give light and ventilation for the halls and stairways.

Some Comments on Shingling

From Edward H. Crussell, California.—I have, of course, been much interested in the various comments upon 'Some Aspects of Modern Shingling' that have appeared in the correspondence columns, and take the first opportunity of answering.

The scaffold bracket of W. M. Spalding, Elmira, N. Y., in the April issue, appears to me to be a satisfactory contrivance and I am glad to know of it.

I think I know why "E. M. P.," Robbinsdale, Minn., in the July issue always recommends the use of the straight-edge in shingling, but never having used, or seen, one of his nailing machines, I am unable to say anything for or against them.

I cannot say that I approve of the method of roof staging of John Upton, La Fargeville, N. Y., in the August issue and I suggest, with all the best intentions, that on his next job he try the method described in the April issue. I assure him that I will not be offended if he does not like the method there mentioned and I hope he will not be offended at my suggestion.

In conclusion I wish to say that the articles are not written in any "I know all about it" attitude, and I hope the readers will feel free to comment upon them in any manner whatsoever, whether to offer new ideas as wrinkles, or criticize anything that has already appeared.

Constructing an Ordinary Shed

From W. M. L., Orange, N. J.—I would greatly appreciate it if Mr. Wilkin or some other practical reader of the paper would furnish information telling how to construct an ordinary shed 12 ft. wide by 18 ft. deep, 9 ft. 6 in. high at the front and 8 ft. high at the rear. In the front are to be 8 ft. x 8 ft. doors.

I also wish to know how the bevels are found.

Floor Plans Wanted for Club House

From S. C. M., Lake Hopatcong, N. J.—Will some of the readers architecturally inclined send to the editor for publication sketches of floor plans suitable for a technical club house for students? The rooms are to be all on one floor, and should include a large reception or meeting room, laboratory, carpenter shop, draughting room and library. The building should be 25 x 75 ft. in plan.

Death of Andrew Richmond

Andrew Richmond, a building contractor of Pittsburgh, Pa., passed away at his home in that city on July 24, at the age of sixty-four. He was born in County Antrim, Ireland, and went to Pittsburgh at the age of eighteen, where he was engaged in business with his son for the past sixteen years.

He was a member of The Builders' Exchange, the Master Builders' Association, the Brick Contractors' Association and the Pittsburgh Chamber of Commerce.

In a recent address before the Southern Forestry Congress, at Ashville, Henry S. Groves, Chief Forester of the United States, emphasized the importance of the timber supply of the South, and pointed out methods by which it may be perpetuated. He stated that 61 per cent of the present hard-wood supply of the country is located in the South, and that many of the most important hard woods are supplied wholly from the Southern forests. He also stated that, at the present rate of cutting, the existing supply of high-grade hard-wood timber will not last many years.

An Apartment House of Stucco Finish

A Compact Yet Convenient Arrangement of Rooms
for Eleven Families in a Three-Story Structure

By CHARLES ALMA BYERS

WHILE from the owner's point of view it is solely an investment proposition, the apartment house, to prove a real and lasting success, must receive careful and well-balanced forethought in a number of different directions. In

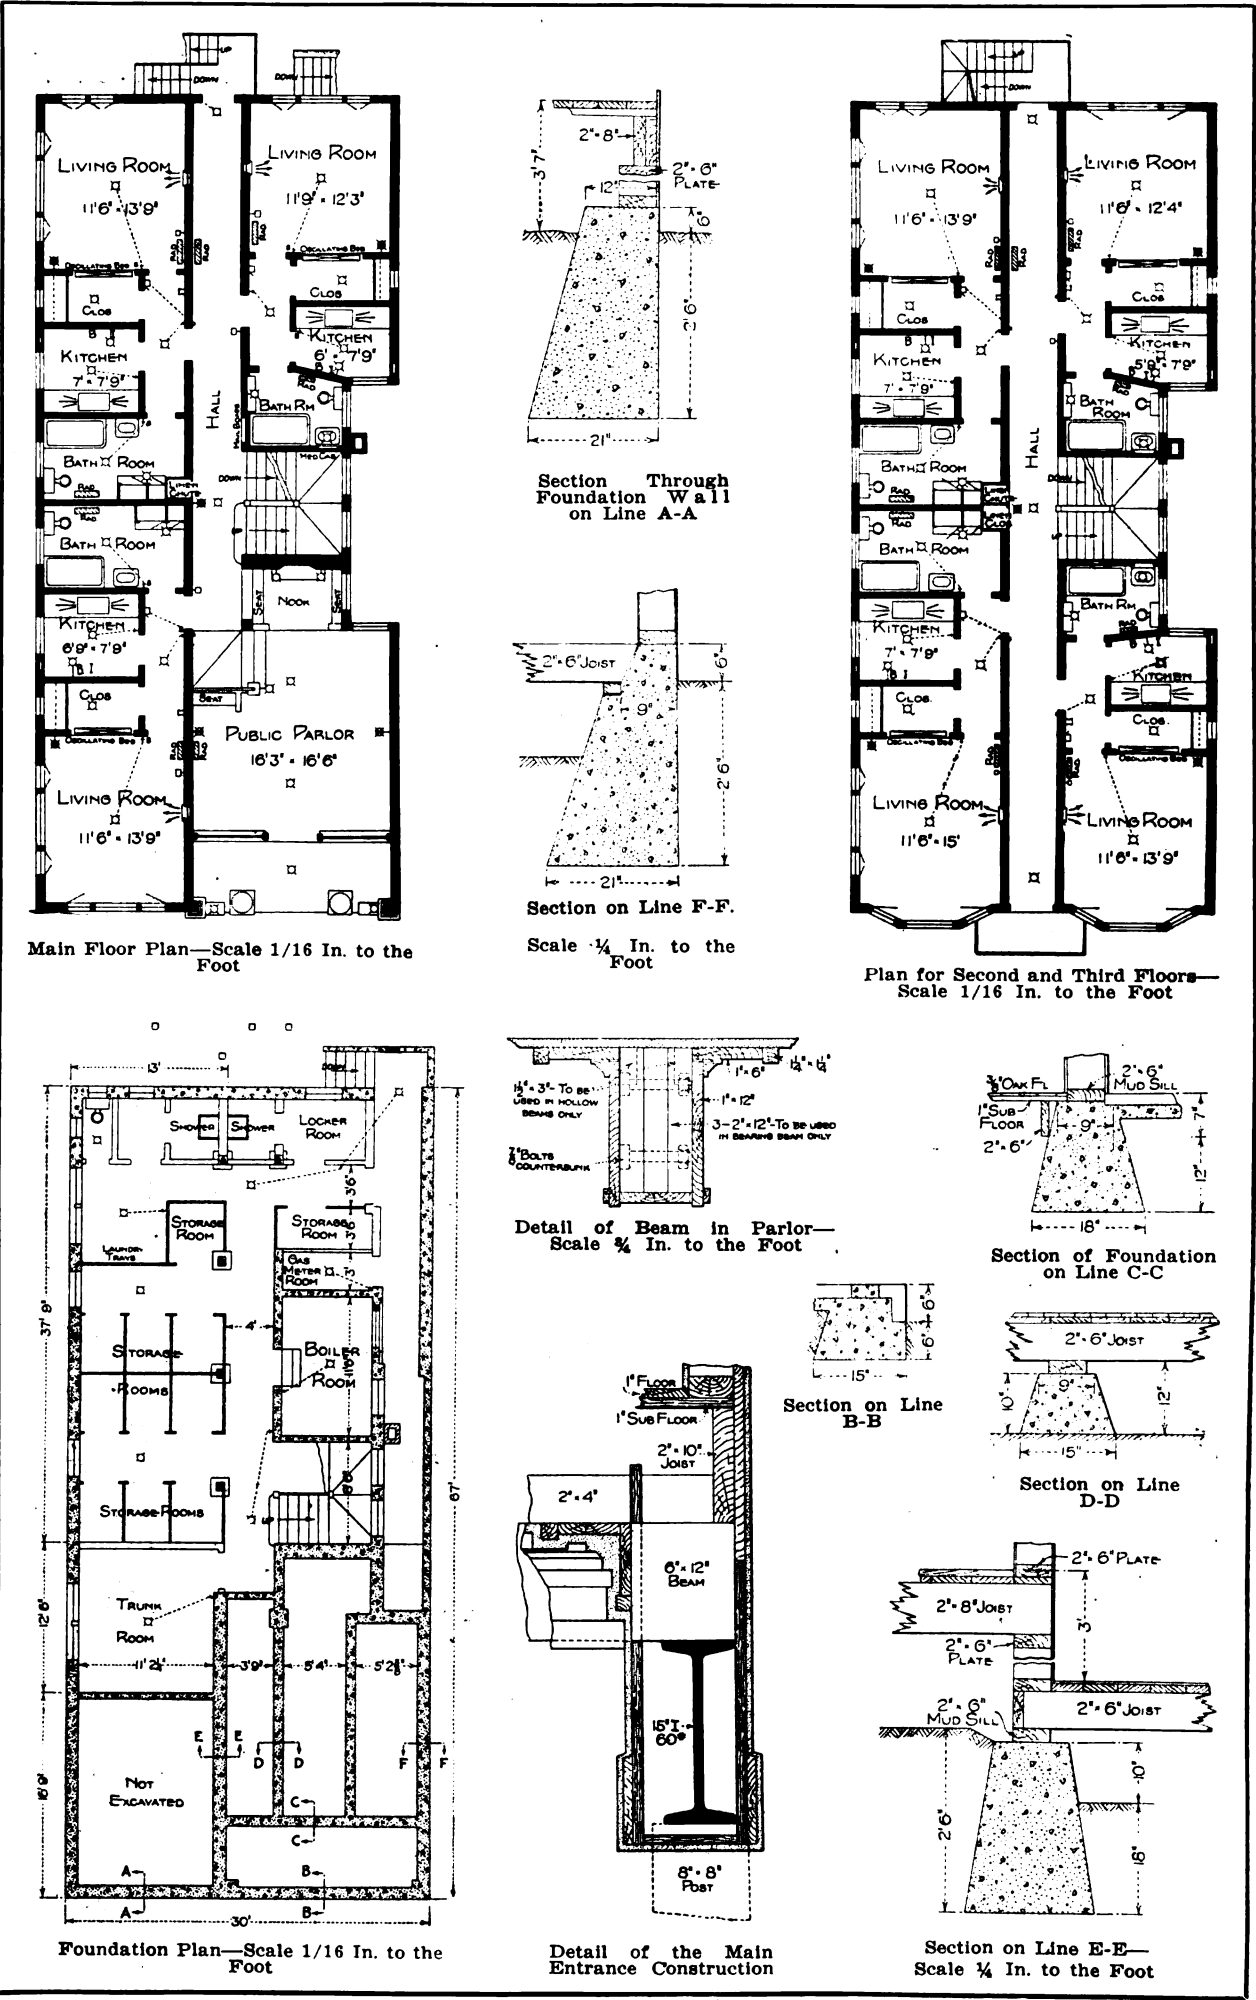

investment, including both the lot and the improvements, with a liberal margin to offset possible vacancies. This phase of the proposition, which, of course, is highly important, is rarely overlooked, although it may often be too carelessly considered

Photographic Perspective of the Finished Building—Architect Albert L. Reed, Los Angeles, Cal.

the first place it should be ascertained, with reasonable certainty, that the size and character of the building and its location will enable the collecting of an average revenue sufficient to pay a satisfactory rate of interest on the total amount of the

to assure safety. But equally important also is the matter of making the building suitably modern and convenient in its interior appointments and attractive in its exterior appearance, so that the apartments may be in demand and periods of vacancy,

An Apartment House of Stucco Finish—Plans and Miscellaneous Constructive Details

or partial vacancy, thereby minimized. Unless this problem is solved, all previous estimates will count for naught, and the whole undertaking automatically becomes a doubtful speculation instead of a businesslike investment.

The apartment house here shown is neither very large nor elaborate, nor does it represent any very great expenditure of money, but it does constitute a well-balanced investment. Moreover, and which is of greater interest, it is a well-planned building—dignified and mildly attractive in outside appear-

in., is covered with a tarred-paper composition, the roof area being inclosed with a low coping-wall extension, with a minimum height of 2 ft. On the front a very attractive cornice effect is created by the introduction of two hood-like sections of red roofing tile, separated by a section of perpendicular wall, rounded off along the top edge and pierced in the center by a group of three Mission arches. At each of the front corners there is also a narrower but similar wall section, pierced by a single arch. These arched openings—five in all—are equipped

An Apartment House of Stucco Finish—The Building Ready for its Coating of Stucco

ance and convenient, economical and modern in interior arrangement. In short, it introduces a number of features, both structural and in the way of appointments, that deserve careful consideration by the prospective apartment house builder.

The outside walls of the building are of cement stucco, of pure white surface, and the trimming, for the most part, is also white. The foundation is of "poured" concrete, and the roof, which is comparatively flat, having a fall that totals but 18

with hidden electric lights, which, together with the two chain-and-brace suspended lighting fixtures of rather elaborate design at the sides of the front entrance, produce at night a most attractive effect.

The front entrance is of the loggia type, the recess being 6 ft. in depth and 16 ft. 11½ in. in width. This area is floored with red brick, laid in herringbone pattern, inclosed with a cement border 8 in. wide, and into the surface of the pillar and pedestal effects at either side of the outer

entrance are set small inlays of hand-made tile. A double door, of square panes of glass, gives access to the interior, and at each side of this doorway is a large plate-glass window, while above both the doorway and the windows is a long transom, divided into three sections. The doors, as well as the framing about both them and the windows, are of plain white oak, finished in a soft bluish-gray shade, or eucalyptus color.

Windows Arranged in Groups of Three

All windows on the front, except those of the entrance, are arranged in groups of three. Beneath the lower group is an attractive window-box, plastered inside and out with Keene's cement, and the four groups above are arranged in shallow bays. Fire-escape balconies project on the front from the second and third floors, and into each of these open French doors. The front and back tiers of windows on the alley side and one tier in the rear end are also groups—the center portion in all such arrangements being a single stationary glass and the side sections being designed as casements, each composed of a single glass panel. All other windows, except those of the closets, are of double casements, but of smaller size, and the closet windows, which are still smaller, are single but open in the same manner.

These casement windows, instead of opening toward the interior, swing outward, and are equipped with rod attachments by which they may be held stationary in any position desired. Where windows of this type open inward it is always difficult to prevent them from admitting water from beating rains, but no such difficulty need be experienced when casements of the outward-swinging type are used, for the buffer strips, or stops, will naturally be on the inside and will cause the water to drain outward instead of toward the inside.

There is an outside iron stairway in the rear, with landings at the different floors, which also serves in emergencies as a fire-escape.

The building is located on a lot that corners on a side alley, convenient access to the rear part of the structure being thereby provided. The lot is 75 x 30 ft. in size and the building covers 86 per cent of this area. It has a frontage equal to the total width of the lot, and a depth of 67 ft., leaving unoccupied margins of 6 in. in front and 7 ft. 6 in. in the rear. On the side opposite the alley, however, there is a small court recess extending to the top of the building, 4 ft. in depth and 19 ft. 5 in. in length.

Arrangement of Rooms

The structure, exclusive of the basement, is three full stories in height. It contains on the ground floor a large public parlor and three complete apartments, and on each of the two floors above are four apartments, making a total of eleven apartments in all. The front entrance leads directly into the parlor, and from one of the rear corners of this room extends, by way of a short flight of steps, a straight, narrow hall, which gives access to the various individual apartment halls on this floor and connects both with the inside stairway and with the outside stairway in the rear. A similar hall, extending the full length of the building, connecting likewise with the stairways and the individual halls, also prevails on each of the floors above. These

main passageways are 4 ft. wide in the clear and the entrance halls of the different apartments are approximately 10 in. less in width in the clear. A linen chute, lined with galvanized iron, with a door on each floor, extends from the top floor to the basement, and on the second floor, only, is a small closet, equipped with shelves, for clean linen. A wall drinking fountain and built-in mail boxes are features of the first-floor hall.

The public parlor, which, in the main, is nearly square, contains, in the rear, a small fireplace nook, which is elevated 6 in. above the common floor level of the room. The fireplace is provided with gas connections for a gas grate, and at each side of it is a built-in seat. Both the floor and the walls, including even the ends of the seats, as well as the entire fireplace of this nook are covered with "Batchelder" hand-made tile of light blue, buff and yellow shades. The seats are 16 in. high, and a similar built-in seat, all of wood, faces the entrance from the side of the steps leading to the hall, while into one of the side walls of the room is built a small cabinet for card tables.

Finish of the "Public Parlor"

The parlor itself is floored with $\frac{3}{4}$ -in. quarter-sawn oak, over two-ply waterproof paper. The ceiling is beamed and the walls are finished with a wainscot and a plate rail. The wainscot extends to a height of 5 ft. 6 in., consisting of five-ply built-up paneling, with battens about 3 ft. apart. The paneling is of select Oregon pine, and slash-grain Oregon pine is used for the remainder of the woodwork of the room—all of which is finished in a dull eucalyptus color, like the entrance outside.

The ceiling of the parlor—the floor of this room being on a lower level than that of the other first-floor rooms—is 12 ft. high, exclusive of the beams, the beams being approximately 13 in. deep. The ceilings of the halls and all other rooms are 9 ft. in the clear.

What Constitutes Each Apartment

Each of the apartments consist of a large living room, a "cabinet" kitchen, a bath room and a roomy closet, as well as a private hall which gives direct access to each of these rooms. Aside from the convenience of the arrangement, one of the particularly attractive features of the apartments is found in the number and the quality of their built-in effects. In every case the living room possesses a full-size disappearing bed, of the "oscillating" type; the bath room contains a small but excellent built-in dresser, with cabinets and drawers and a plate-glass mirror, and a medicine case, in the door of which is set a plain mirror 12 x 24 in. in size. The kitchen has a most complete cupboard arrangement along one wall, while in the wall on the opposite side are a broom closet and a disappearing ironing-board. The wardrobe closet is equipped with the usual shelf, pole and hooks. The kitchen cupboard, it should be added, contains, besides the usual sink, drain-board, shelves and drawers, a draught cooler, an ice-box, a bread-board and a tin-lined flour-bin.

The floors throughout, except in the public parlor, as stated, and in the bath rooms, are of 4 in. No. 1 Oregon pine, over a 1-in. pine sub-floor, two-ply

felt intervening in the case of the second and third stories. In the bath rooms they are of "Flexo-stone," applied over a 1-in. mesh galvanized rabbit wire, to a thickness of $\frac{1}{2}$ in., and which is turned and continued 6 in. up the walls. The woodwork of each apartment, as well as of all halls, is of Oregon pine, and the walls throughout are plastered.

The Tinting and Finish of Woodwork

The tinting and the woodwork finish is particularly interesting and attractive. The woodwork of the living room and individual hall of three of the apartments, as well as of all main halls, is finished, as in the parlor, in eucalyptus color; of two of the apartments, in mahogany; of four of the apartments, in Circassian walnut; and of the remaining two apartments, in silver-gray stain—the imitation eucalyptus and walnut being done in art grain. The furniture of these different-styled rooms is finished to correspond in color. The woodwork of the kitchens, bath rooms and closets is enameled white. The plastered walls are tinted with "Acme No-Lustre," Tiffany blend, seven different color schemes in all being created. The walls of the public parlor, however, are covered with tapestry paper, of indistinct flower pattern.

Since this apartment house is located in a beach city, on the Pacific Coast, where ocean bathing may be indulged in by the tenants, there are certain features of the basement that deserve special mention to builders located in similar resorts. These consist of locker rooms and showers—one each for males and females—located in the rear end of the basement. In each locker room are four individual lockers, which are built against the wall of one end. In inside dimensions each closet is 4 ft. 3 in. high, 1 ft. deep, and approximately 1 ft. wide—the end ones being a little wider in order to fill out the space. A built-in seat, 16 in. high, extends the full width of the four lockers. The showers supply both hot and cold water. Incidentally, in the rear end of the hall on each floor another type of locker is also provided, equipped with shelves and wood and screen doors, for use for various purposes.

The Basement

The basement also contains eleven individual storage rooms—one for each apartment—as well as a large trunk room, a small meter room, a laundry, a lavatory, and the boiler room. It is reached from both the inside stairway and steps in the rear.

The basement, excavated to irregular depths, covers approximately three-fourths of the building plot. Its maximum ceiling height is 9 ft. and its minimum, for the used portion, is 7 ft. It is walled with poured concrete, which, with the piers, consists of good Portland cement, river sand and crushed or broken rock, in a 1-2½-4½ wet mixture, the rock being graded to pass through a 2-in. ring. The flooring consists of concrete also, for which a 1-3/5 mixture is used, and over this concrete, which is 3½ in. thick, is a surface of ½ in. of 1-2 topping, troweled to a smooth finish. Sand screened through a No. 16 mesh screen is used for this surface coat. The floor is naturally sloped toward certain drain pipes.

The entire unoccupied area in the rear of the building, as well as the court on the side, is covered

with concrete and surfaced in the same manner and of the same composition as is the flooring of the basement. This work, however, is marked off into blocks 4 ft. square.

The partition walls of the boiler room are of concrete, but the other basement partitions are, for the most part, of single board or frame construction, all timber being painted white. The walls of the shower rooms are plastered with Keene's cement, but the concrete walls elsewhere, as well as the ceiling, are covered with plaster of ordinary quality. The chimney rising from the boiler room is constructed of hard-burned brick, plastered on the outside and lined on the inside, which is 8 x 12 in. in dimensions, with terra cotta. The basement walls extend some distance above the ground level, and this enables a number of small windows to be used to aid in lighting the interior.

Walls and Piers of Basement

The walls and piers of the basement combine to create the foundation of the building. The piers support 8 x 8-in. posts, set in cast-iron shoes. The mud sills are of 2 x 6-in. redwood, and the girders—two rows running lengthwise of the center—are of 8 x 8-in. Oregon pine, built up from four 2 x 8-in. pieces. The studs and joists are as follows: Underpinning studding, 2 in. x 6 in.; first-story studding (bearing), 2 in. x 6 in.; first-story studding (non-bearing), 2 in. x 4 in.; second- and third-story studding (bearing), 2 in. x 4 in.; second- and third-story studding (non-bearing), 2 in. x 3 in.; first-floor joists, 2 in. x 8 in.; second- and third-floor joists, 2 in. x 10 in.; ceiling joists, 2 in. x 4 in.; and roof joists, 2 in. x 6 in.—all of Oregon pine and set 16 in. on centers.

Double joists are used under all partitions, and all door studs, as well as headers over all openings, are double, while all openings of 8-ft. span are trussed. All plates are single at the bottom and double at the top; and two rows of bridging for each floor, of 2 x 3-in. timber, run the entire length of the building. Surfaced redwood is used for all window sills and casings, outside, and all other framing material is of clear Oregon pine. The partitions are fire blocked in accordance with the local city ordinance. To bridge the weight of the second- and third-floor extension there is used over the front entrance a 15-in. 60-lb. "I" beam, boxed in, and which is supported by two 8 x 8-in. plastered-in. posts. This steel beam in turn carries a 6 x 12-in. wood beam.

Covering of the Exterior of the Building

The entire exterior of the building, as well as all floors and the roof, are sheathed with 1 x 6-in. Oregon pine, surfaced one side, and laid with the surfaced side down, the floor sheathing, or sub-floor, being laid diagonally to the joists.

Over the exterior sheathing is used a new type of plaster-board, and over this is loosely stretched and nailed a wire netting. To this is applied the stucco consisting of a 1:2 mixture of cement mortar 1 in. thick, finished with white cement and white silica sand.

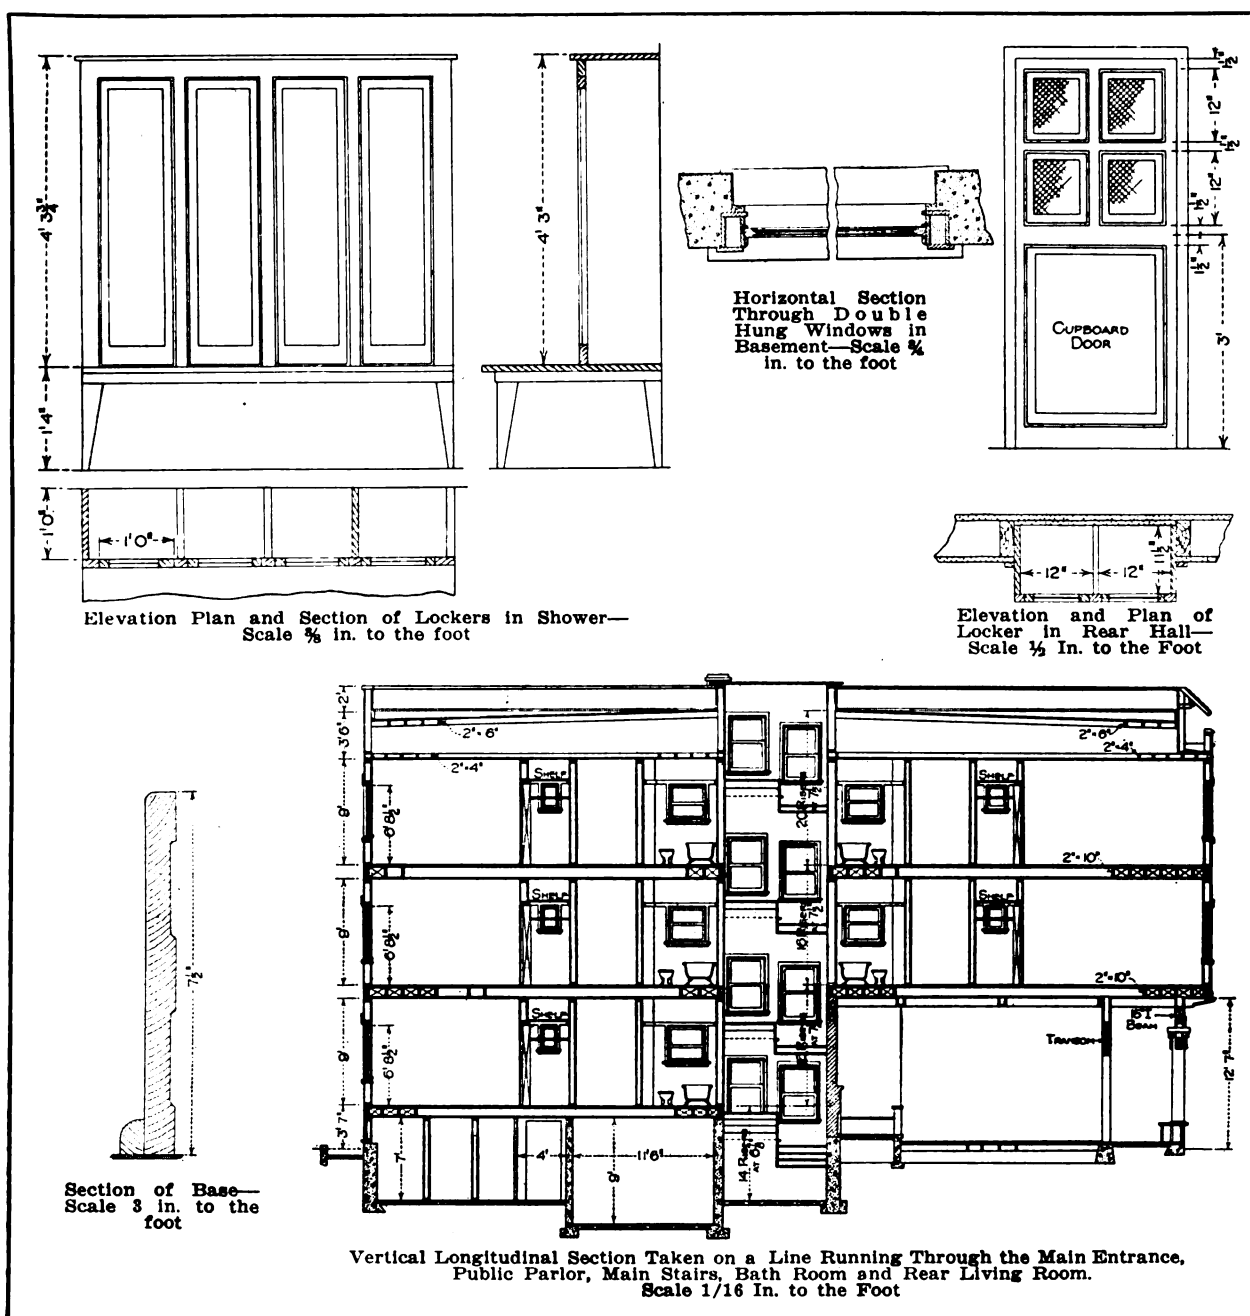

For the interior the plaster is applied over ordinary wood and metal lath, the metal lath being used to cover the ceilings, soffits of the stairs and

the walls and ceilings of the halls, as well as the penthouse inside and out; wood lath is used elsewhere. The dados of the kitchens and bath rooms are finished with Keene's cement, blocked off in the latter in 8-in. squares, and "Victor" hard wall plaster is used elsewhere.

The roof and penthouse are covered with 5-lb. three-ply felt, well mopped between layers with hot tar, and over this is placed a single layer of "Paraffine" rubber-sanded roofing.

The building is heated throughout from a base-

thing represented in the investment except the lot and the furniture, was exactly \$12,970.64. It was constructed almost entirely by day labor, included in this being the concrete work, the plastering, the painting, etc. The plumbing, as well as the heating and ventilation plants, however, were installed, under sub-contract, by S. S. Ford, 58 Lime Avenue, Long Beach, Cal., at a price of \$3,800. The tile work in the public-parlor nook was likewise contracted, it being done by the manufacturer at a cost of \$375. While the other items cannot be segregated to any

An Apartment House of Stucco Finish—Miscellaneous Constructive Details

ment furnace, the system making use of an "Ideal Sectional" boiler and a "Johnson Whirlwind" burner. Radiators are provided in the public parlor and the main halls and in each of the living rooms and bath rooms. A ventilation system, providing for a register in each living room, is also a feature of the building, with galvanized iron pipes leading to the roof. And hot and cold water is supplied to all kitchens and bath rooms.

The total cost of the building, including every-

extent, it may be stated that the excavating and concrete work amounted to approximately \$1,000, and the carpenter labor to about \$2,000.

The building, known as the Dresden Apartments, is located at 125 Daisy Street, Long Beach, Cal., and was designed by Albert L. Reed, architect, 107 West Seventh Street, Long Beach, who was also the general contractor and builder. Mr. Reed has specialized for several years in apartment houses and flat buildings.

Suggestions for Outside Painting

Comments by an Expert Written Expressly for Young Painters and Apprentices—Painting Hard Pine and Cypress

By R. H. FORGRAVE*

WHEN Northern soft pine and poplar were in general use for siding and finishing the outside of houses, almost any kind of paint, provided it contained a sufficient amount of oil, would hold and give good results, failing in few instances. Indeed, I have seen paint stick to the boards so long that so much of the oil had left it that water would soak through it into the boards when it rained, leaving it wet like the surface of unpainted lumber until the sun and wind had dried it, yet the pigment still continued to hang on. In these days of hard pine and cypress it is a question of material more than of anything else.

Getting paint to stand on hard or pitch pines, as it is known in some localities, is a most difficult job sometimes. As to cypress, it is almost as difficult. The scaling of paint on cypress is not so general as on hard pine.

Why the Paint Does Not Stick

What is the reason that paint does not stick well to these woods? Is it because the oil does not penetrate the hard places in the wood, a reason I have heard advanced? I think not. There are just as hard places in oak, ash, beech, etc., and not much trouble is experienced in painting them, if the paint is good. We know that paint adheres well to iron, steel and some other metals with no suction at all. So it must be due to something in the composition of the wood rather than to its texture. If you will examine either of these woods, recently seasoned, with a powerful microscope, you will find that their physical, cellular structure is entirely different, but much alike in the matter that fills the cells, inasmuch as the cells of both are filled, or, rather lined with a substance of a gummy nature. No doubt these gums are different in their chemical composition.

A Varied Experience

My experience in painting these woods has been that of others I have talked to—good, bad and indifferent. I have found the longer they have been seasoned, or, rather, the older the lumber, the better the paint will adhere. I have noticed when buildings, sided with either of these woods, have stood until they have become somewhat weather beaten that little trouble is experienced in making paint adhere. This is proof enough for me that buildings constructed of such lumber should be left to stand awhile, until the sun and rain remove some of the gum. The paint will then give better results. As buildings are generally painted as soon as con-

structed, we must make the paint suit the conditions as near as possible.

As a general purpose paint for outside work there is no paint superior to white lead and oil. In good drying weather no dryer of any kind should be used in the priming coat, and very little in the remaining coats. If one can conveniently do so, it is better to allow each coat to get perfectly dry before another is applied, and use no dryer at all in warm dry weather. White lead is a dryer itself, rather slow, but white lead paint will dry well in a short time during the hot summer months if the oil is right. Don't hurry a job of outside painting with white lead unless you are compelled to do so.

The Chalking of Paint

If white lead is not broken up well, and thoroughly mixed with the oil, the oil and lead will not be equally distributed. I think this is the reason why the paint will begin to chalk on one part of the job before it does on another and before the time it should begin to do so. There is not enough of oil to bind the pigment properly. We are not bothered much with chalking in this part of the country (Ohio). We have a case once in a while which I think is due to faulty mixing more than to anything else.

To break up and mix a considerable quantity of lead and oil properly with a paddle by hand is a tiresome operation. The best way to do it is to take two suitable vessels, a larger and smaller one. Put a hundred pounds or less of lead, ground in oil, in the smaller one, add a little oil, a half gallon, for instance, and thoroughly work it into the lead. Keep on adding a little oil in this manner, working thoroughly into the lead until the mass is of such a consistency that the paddle will move freely through it. Pour into the larger vessel and proceed in like manner until there is enough to do the job, or, at least one coat. Stir this mass thoroughly until you are sure the oil and lead have been equally distributed. Don't be afraid of stirring it too much. I advise mixing enough for the job and stirring frequently while the work is going on.

Proportions of Oil to Lead

This first mixing should contain three or four gallons of added oil to a hundred pounds of lead in oil. Take out enough for the priming coat and temper with oil, stirring it thoroughly; don't just stir it into the top, letting the bottom portion remain heavy. Let the paddle go to the bottom and stir until you are sure the whole is of the same consistency throughout. As some lead will stand more oil than others, I cannot tell you the exact amount of oil to use. In general, however, six to eight

*In a recent issue of the *Painters' Magazine*.

gallons of oil to a hundred pounds of lead will do the work properly. Some practical men use the priming coat so thin, if white, that the pigment is barely perceptible. I do not think this is proper. There should be enough pigment in the priming to serve as a filler to some extent. There must be the proper amount of each in the mixture in order to fortify each other. I have always had the best success when I used about 12½ pounds of lead to a gallon of oil for priming new work.

As I said in the beginning, these two classes of lumber demand a different treatment. Owing to the gum in them, no doubt, it seems that a paint containing turpentine has a better grip on the pores of the wood than a pure oil paint. I discovered this when painting bulletins. A great many bulletin boards are constructed of the cheap grades of both of these kinds of lumber, many of the pine boards containing a large quantity of pitch. Every sign painter knows, when cutting in letters, the quickest and best way to do it is on a flat ground. At first

speak of, open the package and allow the benzine to evaporate and thin with turpentine. All mixed outside paint contains benzine; I do not know if benzine does paint any harm, but it does it no good. It only serves as a thinner and soon evaporates.

In all cases, whether the prime coat be stout or thin, it should be rubbed well into the pores of the wood. The second and third coats should be spread on evenly so as not to have the coats thick in some places and thin in others.

Suggestions for Wall Decoration

Many of our readers are doubtless interested almost as much in the interior decoration of modern homes as they are in the constructive features, and we therefore present for their consideration a picture of a dining-room in an apartment building which has just been finished in the city of Chicago. The panel arrangement is unusually effec-

Suggestions for Wall Decoration—Scheme Adopted in a Chicago Apartment House

we painted them in the usual way, killing the knots with shellac and priming with lead and oil, making the last coat nearly flat. On short-time display signs we simply gave the boards one stout coat of flat paint, working it on in such a manner so as to make it cover. I discovered that work done in this manner often stood better than what we called good work. We often relettered these signs, painting over without burning off. They have stood better than those primed with oil paint, which we painted and relettered in the same way.

To make a primer for this lumber, either kind, mix the lead and oil rather stout and temper with turpentine, as is done in inside painting when a semi-flat finish is desired. It may be finished in gloss, a gloss coat being the best on a flat coat.

As to mixed paint, we have little to say, as the directions for use are furnished by the makers. However, you should be sure that it is of the same consistency throughout. To paint the lumber we

tive and affords possible suggestions that may be of value to builders and house owners generally. The picture which is here reproduced is made from a photograph kindly loaned us by the *Carter Times*, and from it we also take the accompanying descriptive particulars.

The cornice, picture mould, chair rail, panel moulds and all other wood trim was placed first. Then a fine canvas or sheeting was put on between all moulds and trim except in the panels where an exceptionally pretty wall paper, a large leaf pattern in old blue, grays and tan, was used. The canvassed portions were sized, lead coated and finished with white egg-shell enamel along with the wood trim.

The wood trim is birch. Portions not enameled, doors, buffet and quarter-round, were oil stained to a brown mahogany color, shellaced and rubbed with pumice and oil to a dull surface.

The doors are not of the usual panel and stile

type but are perfectly flat, having an inlay of white wood with a black wood inlaid narrow border on each side.

A prettier or more cheerful room would be hard to find and it has manifest advantages over dark walls and woodwork for average apartment dining-rooms, which are notoriously dark and gloomy.

White enamel finish for wood trim and canvas covered walls has become popular indeed of late in the cities. The demand for such work is so great that the larger contractors keep a few especially competent men with fine brushes busy all the time doing nothing but enameling.

Bungalow Operations in Washington

The bungalow type of dwelling is rapidly growing in popularity in Washington, D. C., and in the northeast section of the city there are two squares being built up chiefly with this type of home. It is said the completed operation will number close to 150 homes of bungalows and related types.

The bungalows in this section have from five to eight rooms, open fireplaces, hot-water heat, and the larger ones have two baths. A near-by section contains bungalows set back from the street so as to afford an 18-ft. lawn, the idea in most of the operations being to give comparatively large grounds. Some of the more pretentious houses contain a built-in refrigerator, icing either from the inside or outside.

Not all the dwellings are of frame construction, for at Sixteenth and Irving Streets a bungalow operation has just been completed in which the materials are hollow tile, with a brick front displaying a rug effect in tapestry brick.

Preparing for the Trades at Carnegie Institute

The Nineteen Hundred and Sixteen commencement marked the close of the first decade of the School of Applied Industries, Carnegie Institute of Technology, Pittsburgh, Pa. During the ten years 9772 young men were enrolled as students, 476 of whom have been awarded diplomas or certificates of graduation for completing the regular courses, and have entered twenty-one different industries.

The School of Applied Industries is not a trade school, except in the sense that instruction is offered in twenty-one different trades. The graduate, after completing his three years of training in the day school, does not enter industrial life as a drafts man, a carpenter, a sheet metal worker or a plumber, as is commonly supposed. His training has been of a broader nature, not confining itself to a specialized operation in a single trade nor to the whole of a single trade. It is more concerned with the trades as groups.

A young man interested in building operations will choose the course in building construction, including practical instruction in architectural drawing, sheet metal, plumbing, carpentry, electric wiring, etc. A third course is open to the young man whose interests are in the direction of equipping and installing and taking care of the equipment of

a power plant or of a large building. It consists of the various branches taught under building construction, with special emphasis upon power machinery operation, sanitary equipment and installation, heating and ventilating and electricity.

For a more mature man who, on account of his previous experience in the industries, can profitably take a single trade in which he desires to perfect himself, a one-year intensive trade course is offered. No student who has been inexperienced in the trades is permitted to take this work.

The shop work in all the three-year industrial courses covers but one-half of the instruction. The other half is given over to academic work, which gives the worker the reason for the various operations in the practical training.

The combination of the theoretical and the practical, so closely allied, tends to produce the thinker in the industry instead of the automaton, or rule-of-thumb worker. The broad scope of the training in any particular course makes it possible for the graduate to start his outside work with an unusual amount of intelligence for a worker in the industry. The logical next step for him is a position of leadership as a foreman, superintendent or manager.

In addition to the day courses, the Night School of Applied Industries is a powerful factor in training workers, especially for the local industries. This is in the nature of a continuous school where the young man works at his trade during the day and comes to school for three nights a week, two hours each night. With the use of the school shop equipment, and under the instruction of expert workmen, as well as instructors in mathematics, English, chemistry, physics and drawing, a rare opportunity is afforded him to become a more efficient workman. Among the night courses are plumbing, heating and ventilating, plan reading, steam engineering, sheet metal and cornice work, electric wiring, patternmaking, foundry, forging and machine shop.

Meerschaum as a Building Material

Even the most aesthetically inclined of our American millionaires would hardly consider the luxury of living in a palace built of meerschaum as within the range of their fortunes, yet there are many unpretentious houses of this material in the Spanish town of Vallecas, near Madrid, where a coarse variety of this substance is to be found.

Getting Out Stock Window and Door Frames

Often those planing mills and lumber companies which buy window and door frames in large lots encounter the problem of not being able to get all the different kinds or styles of frames they need in their business, says S. Irvin Baer, in a recent issue of the *Woodworker*. I have been up against this same problem, and have solved it in the following way:

The sketches, Figs. 1 and 2, show window and door frames that can be used for different walls, but the door frames cannot be used for heavy brick walls. The window frames can be used for sheathing and lap siding, cove siding, lap siding only,

cove siding with $1\frac{1}{8}$ -in. casings and the cove siding cut between the casings, brick veneer walls and brick walls. Fig. 2 shows $1\frac{1}{8}$ -in. casings, a wide cap on head, and sill relished only $4\frac{1}{2}$ in. The reason for this wide cap is so it may be used for cove siding and set back of same. The $4\frac{1}{2}$ -in. relish is, if only $4\frac{1}{2}$ -in. jamb is used, as for lap siding without sheathing and casings, set on studs and lap siding cut between casings. If $\frac{7}{8}$ -in. casings are wanted, such as cove siding to set outside of cove siding, they can be surfaced down from $1\frac{1}{8}$ to $\frac{7}{8}$ in. If brick veneer frames are wanted, all that is necessary is to put a brick mold on casings; and for box frames for brick wall it is only necessary to put brick mold on casing, build a box on, and pull the sill out so it will project a little over brick mold; this may be easily done by rebating the shoulder back farther.

In our mill we have found this to be a help, not only in getting orders out faster, but in making the frames, as we can buy them by the carload, and only have to buy one kind; it would make a lot of

encourage the hope that it will be made a regular annual summer event.

The lectures and classes were conducted by the experts of the association and others prominent in the cement world. The course included discussions and demonstrations regarding materials which enter into concrete, tools and equipment, principles of reinforcing, ornamental surface finishes, plaster and glue mold work, etc. Demonstrations of the latter were carried on by instructors and students of the Mooseheart Institution in one of the laboratories, while demonstrations of slab and floor work, column work, etc., were conducted outside the building. Other lectures and classes were held in the classrooms and auditorium.

Permanent Exhibit of Woods and Stains

A permanent display of all the building woods in America is to be installed at Chicago, Ill., in the Insurance Exchange Building, where the lumber

Fig. 1—Section and Elevation of Door Frame

Fig. 2—Section and Elevation of Window Frame

Getting Out Stock Window and Door Frames

trouble to carry frames for the different styles. It takes only a few minutes to make such a frame to suit the order, and in buying them by the carload very attractive prices can always be had. While these frames cannot be used for all classes of work, they will come in very handy for the ordinary house, and will prove themselves a great saving. A careful study of sketches will show how we worked out this problem.

Course in Concrete for Manual Training Teachers

An increasing number of manual training and vocational schools are placing concrete construction in their curriculum, for its growing popularity and importance are such as to commend it to the student. With a view to aiding teachers in their work, the Portland Cement Association held a week's course in concrete construction during the latter part of June at Lewis Institute, Chicago, under the auspices of the Extension Division of the Association. The course attracted nearly 200 teachers, both men and women, and the success was such as to

manufacturers of America are planning to provide an exhibit that will give any builder an idea of what can be done in the house he is contemplating. All sorts of finishes and various types of construction will be on display.

There will be cases containing hundreds of panels of woods, in the natural finish, and in stains. There will also be, for building engineers, an exhibit of treated and untreated woods, good and bad structural material, giving concrete examples of what kinds of wood to select for various building purposes. One of the displays will be a large model of a building of "mill construction," showing floors, roof timbers, pillars, and all the interior work on a factory building of large size.

There will be several models of farm buildings, and also of four frame houses to cost from \$2,000 to \$8,000 each, preferably for houses in the city. Sidewalks, creosoted block roads, models of garages and chicken houses will also be provided. One exhibit will be of large-sized specimens of structural material and other such phases of the industry. Eventually, it is planned to install such an exhibit on a modified scale in every large city in the country, to provide information for prospective builders.

Construction of Roofs in Scotland

The General Method of Procedure in Scotland—Some Interesting Details of the Work

BY JOHN Y. DUNLOP

IN taking up the matter of the construction of roofs in Scotland I have deemed it advisable to show a method which has been long in use in different parts of the country. The system might not suit every purpose and would be entirely out of place in connection with very small roofs, but for the general run of work of the carpenter-contractor, and more especially those who execute large contracts, the method shown is worth consideration.

Things with Which the Carpenter Is Supplied

When a building is erected in Scotland the carpenter in most cases is supplied with a roof plan and a detail of the spar at the junction of the wall such as shown in Fig. 3. He is also given the detail specifications in which the size of the roof timbers is noted and the nature of the labor at the joint.

From these he is able to lay down full size a section of the roof so that a template can be made of the different roof timbers. From the plan, Fig. 1, he is also able to obtain the length of the valley rafter or flank plate should he adopt that method.

In erecting the roof shown in Fig. 1 most of the carpenters here in Scotland would allow the main roof, which extends from gable to gable, to run right through, then have it boarded on five sides leaving a small portion blank where the wing roof would meet the main roof. The wing roof would then be set up and the flank plate, which is a piece of 1 x 9-in. timber, laid flat on the roof boarding so that the outer edge is contained by the plane which is formed by the upper edge of the roof spars, nailed in position. The jack rafters are then cut to fit on the flank and ridge, as shown in Fig. 5.

The advantage of this method, which is fully appreciated in Scotland, is that it does away with the long and heavy flank rafter, saves the cutting of a great number of jack rafters, and as most of this work is paid for by the square yard of sloping surface it pays the contractor much better to adopt the flank plate system.

One Method of Framing the Roof

Another method which Scotch contractors sometimes adopt is to cut the whole of the roof timbers with a circular saw in the yard, or with a portable saw on the job. This is another great saving, provided of course there is no trouble in erecting.

In a case such as this, say with a roof similar to that shown in Fig. 2, the roof plan would be used to obtain the dimensions of the spars, and the hip and valley rafters. The roof would then be set up in sections full size and the templates made for the common spars.

In erecting, the common spars would be set up,

then the position of the flank rafters and the hip rafters determined, all as shown in Fig. 6. The position of the jack rafters on the valley and hip rafters would now be marked off and the length of each taken and marked on a board.

Fig. 7 represents a dimension board for this roof with the three bevels which would be required in the cutting of the jack rafters. The plumb bevel for the top end, the level bevel for the bottom and the side bevel for the edge of the top end are shown. The measurements of the jack rafters for one end of the roof are also shown in Fig. 7. This measurement board when complete is sent along to the mechanic to have the material prepared.

Setting Up the Framing Timbers

In setting up the different lengths of the spars they should be drawn in pairs, as this prevents mistakes, such as cutting too many for one side. Fig. 8 shows one pair set on the bevel drawn ready to be cut.

The timber is now taken along to the saw and cut by allowing it to rest on one arise, then tilting slightly back so as to bring the setting-out line in a true plane with the revolving saw, as in Fig. 9.

In some cases the spars are required to be marked for the part of the roof for which they have been cut, but this is a small matter compared with the setting out and cutting of a heavy roof, as very often it has to be done on insecure footing and at a giddy height.

Mammoth Loft Building

It has been decided to increase the height of the four-story post office and express building covering the block between Lexington Avenue, Forty-fifth and Forty-sixth Streets, New York City, to twenty stories, and plans for the work have recently been filed. The plans provide for the extension of the building over the street at the rear of the Grand Central Palace to Park Avenue, and all the new stories are intended to be occupied as lofts.

The completed building will cover an area of 200.10 x 405 ft., or about 81,400 sq. ft. to a floor, thus making a total for the sixteen new stories of 1,302,400 sq. ft.

Annex to the Hotel McAlpin

The proposed annex to the Hotel McAlpin, West Thirty-fourth Street and Broadway, New York, will make that structure what is said to be the third largest hotel in the world. The addition is to be twenty-three stories in height and will contain 200

rooms, making a total, with the main structure, of 1700 rooms. A feature of the annex will be the large amount of space devoted especially to women, a large ballroom, a children's playground, and, on the roof, an outdoor playground.

The annex is estimated by the architects, Warren & Wetmore, to cost \$1,000,000. Construction work is being done by the Thompson-Starrett Co.

Kinds of Lumber Cut in 1915

The lumber cut of 1915, by principal kinds, has just been compiled by the Forest Service, with results shown in detail in the table below. Southern yellow pine, with a total cut of 14,700,000,000 board feet, forms 30 per cent of the total, and was more than three times the cut of Douglas fir, the second on the list. Oak, white pine and hemlock are the only other kinds showing over 2,000,000,000 ft.

1915 Lumber Cut by Species

Kind of Wood	Probable Total, M Ft.	Reported M Ft.
Yellow pine.....	14,700,000	12,177,335
Douglas fir.....	4,431,249	4,121,897
Oak.....	2,970,000	2,070,444
White pine.....	2,700,000	2,291,480
Hemlock.....	2,275,000	2,026,460
Spruce.....	1,400,000	1,193,985
Western yellow pine.....	1,293,985	1,252,244
Cypress.....	1,100,000	926,758
Maple.....	900,000	771,223
Red gum.....	655,000	478,099
Chestnut.....	490,000	399,473
Yellow poplar.....	464,000	377,386
Redwood.....	420,294	418,824
Cedar.....	420,000	352,482
Birch.....	415,000	355,328
Larch.....	375,000	348,428
Beech.....	360,000	303,835
Basswood.....	260,000	207,607
Elm.....	210,000	177,748
Ash.....	190,000	159,910
Cottonwood.....	180,000	138,282
Tupelo.....	170,000	153,001
White fir.....	125,048	121,653
Sugar pine.....	117,701	115,109
Balsam fir.....	100,000	71,358
Hickory.....	100,000	86,015
Walnut.....	90,000	65,144
Lodgepole pine.....	26,486	22,672
Sycamore.....	25,000	19,729
All other kinds.....	49,531	37,826
Total.....	37,013,294	31,241,734

The figures include both the actual reported cut from the mills making returns and the estimated probable actual cut. The total cut of all species is shown as 37,013,294,000 ft., as has been previously announced by the Forest Service. It is believed that at the outside the grand total 1915 lumber cut did not exceed 38,000,000,000 ft.

The actual reported cut of lath in 1915 was 2,745,134,000 and the estimated total cut 3,250,000,000. For shingles, the reported cut was 8,459,378,000 and the estimated total cut 9,500,000,000.

Because of the closer touch of the Western offices of the Forest Service with the mills in their territory, and the consequent greater accuracy of the estimates of probable total cut of the Western species, the figures for these species are not rounded off as are the corresponding figures for other kinds. The many thousand mills east of the Rocky Mountains make estimates of more than approximate accuracy impossible.

Local Building Operations in July

The amount of new construction work for which permits were issued in July by the Bureau of Buildings in each of the five boroughs of Greater New York makes a highly gratifying exhibit when compared with the figures for the same month last year. The total is \$50,526,144, as against \$12,246,489 a year ago, the cost of alterations to buildings being omitted in both instances. Of this enormous total for July, 1916, the Borough of Manhattan furnished \$45,472,250, which is the estimated cost of the 101 new structures for which permits were issued by Superintendent Alfred Ludwig of the Bureau of Buildings. Counting in the cost of alterations to 404 buildings of \$3,732,970 gives a total for the Borough of \$49,205,220. These figures contrast with 50 new buildings for which permits were issued in July, 1915, estimated to cost \$4,097,080, and alterations to 268 buildings estimated to cost \$748,223, or a total of \$4,845,303.

This tremendous increase in Manhattan over last year was due almost wholly to the rush of builders to anticipate the new measure which is designed to not only place a restriction on tall buildings but to check the invasion of retail districts by factories and business streets. This measure was unanimously adopted by the Board of Estimate on July 25 and during the two or three days prior to its adoption plans were filed for operations involving an estimated outlay of more than \$20,000,000.

According to classification plans were filed in Manhattan for 23 apartment houses, to cost \$11,665,000, against 19 in July last year, to cost \$1,585,000. Of hotels 11 were planned last month to cost \$9,930,000 against one a year ago costing \$60,000. There were 18 store and loft buildings planned last month to cost \$11,955,150 against 8 a year ago, to cost \$1,444,000. Of office buildings 14 were planned last month, to cost \$7,581,000, against none a year ago; 10 manufacturies and workshops, estimated to cost \$2,670,000, against 2 last year, to cost \$3,000; 2 places of amusement, to cost \$160,000, against one last year, costing \$40,000, and 11 garages, to cost \$528,000, against 12 in July last year, to cost \$122,080.

It will be seen from these figures that of the \$45,472,250 which is the estimated cost of the new construction work planned last month, four classes of buildings account for \$41,131,150 of the total.

Registration of Architects

The law which recently went into effect in New York State regarding the licensing of architects is rather more exacting than that in some of the other states. For example, it provides that nobody must practise under the title of "architect" unless he has received a certificate of qualification from a board of five examiners. In New Jersey, however, a diploma or other evidence of graduation from a full course of architecture may be accepted as a satisfactory evidence of competent knowledge of architecture, design and construction. In New York this must be supplemented by at least three years' practical experience.

In New Jersey, again, any person who was engaged in the practice of architecture when the act

was passed, and presents an affidavit to that effect, is entitled to receive a certificate without further test. In New York the act provides that an architect must have been engaged in the profession for more than two years before the passage of the act, and must also present satisfactory evidence as to character, competency and qualifications before he is entitled to a certificate.

Moving a House with an Automobile

Many and varied are the uses to which automobiles have been put since they became so popular with the public, and the wide-awake contractor and builder is ever on the look-out for new "stunts" which may be performed in connection with a machine of this nature. The accompanying picture shows the unique manner in which an automobile was utilized to help a house mover out of the predicament in which he found himself.

total output, said R. S. Kellogg in an address before the National Association of Owners and Managers of Buildings at one of its more recent meetings, is used for mill work which includes all kinds of interior finish, high-grade flooring, veneered doors, etc., and in the manufacture of furniture and fixtures. In fact, it is in the field of interior finish that birch finds its most appropriate use.

There are as many styles of birch trim as there are designers who wish to produce an unusual or particularly appropriate effect. The author expressed a preference for the simpler styles which offer the fewest possible angles and corners to collect dust, and at the same time give the largest uninterrupted surface to display the figure and sheen of the wood itself. For the same reason his choice is for the softer hued stains which bring out the qualities of the wood in harmonious fashion, rather than for more brilliant colors or paints which obscure the natural beauty of the wood.

Great progress has in recent years been made in the manufacture of artistic veneered doors, of

Moving a Two-Story and a Half Frame House by Means of an Automobile

A two and a half story frame house was being moved in Tulsa, Okla., and the horses attached to the cable were having a hard time of it in pulling the weighty building. Just then the sales manager of the Carhart Motor Company happened to be passing the scene of operations in an Overland "Six" and noting the predicament of the horses had his machine hitched to the cable and its 45-hp. motor soon started the building on its journey, while the horses, not to mention the men, seemed to view the proceedings with an expression of great relief.

Birch for Interior Finish

It is a well-known fact that birch is one of the most widely useful of woods, a recent tabulation of factory reports showing that it is used for nearly 200 distinct purposes. More than half the

which many styles are available. One of the most pleasing is a single panel birch door stained silver gray, but other styles have many admirers.

The demand for conveniences and economy of space has resulted in a wide variety of built-in work, all the way from kitchen to bedroom. Built-in bookcases, china closets, sideboards and wardrobes are considered among the necessities of the modern residence. For them no wood is superior to birch. In addition to its desirable qualities of figure and color, birch looks well and fulfills every requirement of high-grade cabinet wood. We have all seen beautiful examples of built-in work that harmonizes perfectly with finish and furniture, which are also the ultimate of convenience and utility.

As to where we shall use birch, I would say everywhere in the interior of your building. It is of proved worth for such hard service as store counters, showcases and fixtures, while its merits

make it just as appropriate for trim of the finest residences, apartments, offices and hotels. Moreover, the reasonable cost of birch places it easily within the reach of the builder of the modest cottage or bungalow. The Colonial hall and stairway in white enamel, the living-room in silver gray, the dining-room in one of the many shades of brown, the bedroom in white enamel or natural, the den to suit the owner's particular fancy—all offer suitable opportunities for the use of birch.

Among the stains which I like best on birch are silver gray, walnut, fumed oak, natural and Mission brown. These are colors which harmonize well with general schemes of decoration, and are not likely to get on anybody's nerves. However, I have no quarrel with the user of birch who prefers an entirely different selection. The wood will take and hold permanently any stain of the right kind that is properly applied. An authority says that "Birch is the ideal high light for a scheme of coloring in browns with notes of blue and orange"; also that silver gray is beautiful in a room with walls of dull old blue, and a ceiling of silver gray on which are frescoed pink old roses, but not being a professional decorator, I shall have to go carefully here.

One of the best features of birch is that it combines so well with other woods. I have seen excellent combinations of maple or oak floor with birch trim, and of birch veneered doors with a trim of other woods or white enamel. Your own observation will furnish a multitude of instances of this sort. It is evidence enough of the qualities of birch and its popularity with architects to say that it is used in leading hotels, apartment houses, office and banking buildings, and in uncounted residences throughout the country.

Outing of Ohio Builders' Supply Men

The summer outing of the Ohio Builders' Supply Association was held at Cedar Point, July 27, 28 and 29. About 150 members were present and are said to have thoroughly enjoyed themselves.

During the outing President W. O. Holst called to order a short executive session at which it was decided to hold an evening meeting for the purpose of listening to H. S. Gaines, the official organizer of the National Builders' Supply Association, who made an interesting and suggestive speech about the possibilities of increasing the membership by means of the district organization plan. He made such an impression that the idea is to be taken up at an early date.

An exhibition of the work of the pupils of the Baron de Hirsch Trade School, 222 East 64th Street, New York City, was given on Thursday evening, July 13, from seven until ten o'clock. The display attracted much interest on the part of visitors, showing as it did a most creditable degree of proficiency by the pupils.

Lincoln, Neb., is said to be enjoying the greatest building boom in its history.

New Publications

Electric Wiring Diagrams and Switchboards. By Newton Harrison, E. E., with additions by Thomas Poppe. 272 pages, size 5 x 7½ in. Illustrated by 129 diagrams. Bound in flexible cloth. Published by the Norman W. Henley Publishing Co. Price, \$1.50.

Electricity as a means of illumination for dwellings and public buildings is rapidly gaining in popularity, and new structures erected in sections where the current can be secured from a public main are wired for the purpose. The book under review, now in its second edition, is stated to be "A practical, comprehensive treatise explaining the theory and design of wiring circuits," and a "guide for all interested in the application of electricity to illumination and power." As such, it contains much valuable material presented in a fashion to afford the reader a good knowledge of the subject. Those who have no knowledge of higher mathematics will find the work within their understanding, for all calculations and examples are limited to the use of arithmetic, both in the case of direct and alternating current.

The work treats of the fundamental principles of electricity, wiring systems and functions of mains, feeders, etc.; resistance, types and connections of motors; switchboards, their parts and purposes; generators for alternating and direct current lighting, and many other things of an interesting and instructive nature.

Gothic Ornaments. By A. Pugin. 92 full-page plates, size 11½ x 9 in. Bound in cloth. Published by J. Tiranti & Co. Price, \$5.00.

The Gothic period saw the erection of some of the most sublime and beautiful structures known to architecture. Gothic influence and tradition are still living and vital forces of to-day, and therefore many architects make a special study of this phase of their work. Of interest and value to such is the book under review, for it is a new edition of a work originally printed in 1831 and reproduced in 1854 which had for its purpose the reproduction of Gothic ornaments selected from various ancient buildings erected during the period from the eleventh to the sixteenth century in England and France.

Wood carvers everywhere refer to it for really sound detail of the best practical examples of various kinds of Gothic work, and it is described as "one of those Technical Art Books which never get out of date." The few matters which have been revised have been solely in the direction of facilitating reference and greater handiness. The illustrations, which are reproductions of charcoal drawings, are of sufficient size to enable an architect to easily catch the details. Some of the subjects treated are arms, bosses, canopies, dogtooth ornament, elbows, finials, grotesques, panels, tracery, spandrels, weepers, etc. The present edition is said to be limited to 500 copies.

A pamphlet, describing with great clearness and force the need of a state regulation of plumbing, house drainage and ventilation, is being distributed through Texas under the auspices of the Texas Association of Journeymen Plumbers.

Brief Review of the Building Situation

Building Operations for July in 119 Cities Show
an Increase of 72.48 Per Cent Over July, 1915

THE outstanding feature of the building situation as it is reflected by the reports of operations for which permits were filed in July, is the very unusual increase of 72.48 per cent for 119 cities, as compared with the activity in new construction work in July a year ago. This is particularly noticeable in the eastern section of the country, where the gain in the cities reporting is nearly 134 per cent. An analysis of the figures, however, shows that this very gratifying exhibit is largely due to the rush to file plans of imposing structures in the Borough of Manhattan, New York, before the measure restricting the heights of buildings and preventing the erection of factories in the retail districts was adopted. Eliminating New York City from the calculation shows the gain for the 119 cities reporting to be only 7 per cent. The number of permits issued during the month shows an actual decrease as compared with July, 1915.

From the Eastern section of the country we present reports from 47 cities, of which 16 indicate increases and 31 decreases, as compared with last year, or a total gain of 133.84 per cent. Eliminating the figures for the Borough of Manhattan, New York, for reasons stated above, and the showing is a loss of 8.7 per cent. A comprehensive idea of the activity during the two periods in the Eastern cities reporting may be gathered from an inspection of the table which follows:

CITIES OF EASTERN STATES

	July, 1916	July, 1915
Albany	153,325	416,760
Allentown	62,280	79,075
Altoona	71,221	85,031
Atlanta	200,717	613,146
Auburn	39,570	43,401
Bellefonte	29,305	21,040
Binghamton	144,831	146,599
Boston	4,912,000	5,483,000
Bridgeport	464,157	1,061,200
Brockton	104,612	84,517
Buffalo	1,135,000	1,494,000
East Orange	225,859	144,848
Elizabeth	121,305	118,382
Erie	255,781	283,700
Harrisburg	90,215	144,325
Hartford	363,756	441,767
Haverhill	101,950	145,000
Hoboken	109,790	48,078
Holyoke	97,400	178,915
Lawrence	68,650	56,375
Manchester	87,511	309,050

Trenton	114,985	385,521
Troy	62,373	125,161
Utica	157,900	112,205
West Haven	50,315	335,725
Wilkes-Barre	185,580	45,133
Worcester	526,545	703,329
Yonkers	291,200	346,700

In the Central West, or Middle States, the 37 cities reporting indicate an increased activity in the projection of new construction work of 26.22 per cent as compared with July a year ago. The noticeable centers of activity are Chicago, Detroit, Milwaukee, Minneapolis, St. Louis and Youngstown, while Akron, Cincinnati, Dayton, Evansville, Kansas City and South Bend are some of the more noticeable showing a falling off in activity.

CITIES IN MIDDLE STATES

	July, 1916	July, 1915
Akron	756,425	1,148,750
Cedar Rapids	146,000	167,000
Canton	341,440	247,450
Chicago	8,076,800	6,455,630
Cincinnati	768,350	1,275,100
Cleveland	3,397,660	2,319,280
Columbus	563,085	504,085
Davenport	123,060	46,355
Dayton	350,805	232,105
Des Moines	138,383	181,405
Detroit	4,622,590	2,683,080
Dubuque	84,800	23,100
Duluth	172,240	201,422
East St. Louis	51,450	142,976
Evansville	242,781	396,770
Fort Wayne	289,500	202,580
Grand Rapids	246,822	211,639
Indianapolis	818,979	598,078
Kansas City, Mo.	1,108,140	1,418,060
Kansas City, Kan.	51,940	77,177
Lincoln	157,275	272,335
Milwaukee	2,067,794	844,967
Minneapolis	1,913,175	1,474,265
Omaha	584,675	556,780
Peoria	166,435	121,190
Saginaw	63,965	54,897
St. Louis	1,541,421	615,148
St. Paul	782,224	770,018
Sioux City	299,150	218,200
South Bend	97,652	229,210
Springfield, Ill.	103,100	63,400
Superior, Wis.	71,155	52,250
Terre Haute	69,740	109,140
Toledo	565,492	534,012
Topeka	101,893	168,891
Wichita, Kan.	135,800	89,825
Youngstown	274,800	147,650

Of the four zones into which the country has been divided in reviewing the building situation, the Southern is the only one showing a loss as compared with last year. Of the 19 cities reporting from this section, 8 show gains and 11 losses, with a total loss of 11.57 per cent. The largest gain is reported by Washington.

CITIES IN SOUTHERN STATES

	July, 1916	July, 1915
Baltimore	618,218	695,375
Birmingham	141,418	223,987
Chattanooga	39,984	32,375
Dallas, Tex.	268,176	656,124
Fort Worth	257,220	220,029
Houston	196,341	164,720
Huntington	102,100	132,040
Jacksonville	214,275	187,382
Louisville	185,380	599,320
Memphis	261,405	245,285
Montgomery	40,481	40,810
New Orleans	381,126	513,510
Norfolk, Va.	103,612	163,575
Oklahoma City	183,575	81,530
Richmond	269,169	328,667
Savannah	132,095	154,840
Tampa	79,425	82,010
Tulsa	285,500	242,865
Washington	1,814,753	1,424,207

In the extreme West, taking the territory lying beyond Denver, 16 cities report a gain over July last year of 18.7 per cent. The striking increase is that reported by Seattle, due largely to the filing of plans for two large fireproof structures estimated to cost \$545,000. Spokane also shows an important gain, as do Denver, Salt Lake City and Tacoma.

CITIES IN EXTREME WESTERN STATES

	July, 1916	July, 1915
Berkeley, Cal.	121,350	182,100
Colorado Springs	55,025	22,690
Denver	348,770	177,090

Current News of Builders' Exchanges

Various Matters Likely to Prove of Interest to Members of Exchanges Throughout the Country

Convention of North Carolina Builders' Exchange

THE semi-annual convention of the Builders' Exchange of North Carolina was held at Wrightsville Beach on Aug. 2 and 3. Meetings of the general contractors, sub-contractors and material men who belong to the Exchange occupied the first day and the general meeting was held on the second day of the convention.

A number of interesting addresses were made, including one by Joseph Litener, ex-president of the North Carolina Architects' Association. The social features of the event were enjoyed by all.

Outing of Grand Rapids Builders' Exchange

The fourth annual outing of the Builders' and Traders' Exchange of Grand Rapids, Mich., held on July 29, was enjoyed by two hundred members and their guests, among whom were included representatives of the Plumbers' Association, the Engineering Society and various architects of the city. They were conveyed by automobiles to Crooked Lake and once arrived there showed that the building business has no bad effects on appetites, for there had been provided for them a roasted ox, five bushels of green corn, 100 berry pies and ten gallons of coffee. Some of the members complained of the heat so the committee called off the greased pig event because the grease was so hot it would not stick. The principal event of the afternoon was a ball game between teams from the building contractors and the Master Plumbers' Association, the prize of a silver loving cup being won by the plumbers. Other events were a tug-of-war, in which the material men defeated the contractors, foot races, a balloon ascension and a parachute drop by the Moore brothers.

Membership Campaign and Banquet of Flint Exchange

The membership campaign of the Builders' and Traders' Exchange of Flint, Mich., has been gratifyingly successful, for the one hundred mark has now been passed and one-half of this number is the result of the recent campaign.

On Aug. 4 the members of the Exchange entertained a delegation of the Builders' and Traders' Exchange of Detroit at a banquet given to celebrate the growth of the former body, which is now two years old. Several interesting addresses were made by officials of the Detroit Exchange, including President W. A. C. Miller, Treasurer T. E. Beck and Secretary Charles A. Bowen.

Chicago Builders' Exchange Has a "Dutch" Luncheon

Members of the Builders' and Traders' Exchange of Chicago, Ill., had a most enjoyable time in the association's club rooms in the Chamber of Commerce Building on Thursday evening, July 27, when a Dutch luncheon was served. This affair was held in lieu of a regular outing, and during the evening an entertainment program enlivened the proceedings to an appreciable extent. Refreshments and a wide variety of inviting comestibles were served to about two hundred members and friends, and a number of prospective members were present to see the enthusiasm that is an unwritten law of the exchange. The officers of the exchange were on hand to greet everyone and the affair was voted a most successful one.

The Situation in Buffalo

In writing of the situation in that city, F. N. Farrar, secretary of the Builders' Association Exchange, Buffalo, N. Y., says:

Our exchange had an automobile run Tuesday, July 18, and wound up at the Auto Club's country home for a splendid dinner. The event of this month will be a river party in the shape of a trip around Grand Island. The usual outdoor sports will be a feature, including a ball game, which, in view of the fact that the exchange has some very good players, ought to be an interesting event.

Practically every trade in the building line is asking for an advance in wages, regardless of the fact that they are already exceedingly well paid and that the average employer is trying to recover from the effects of two very lean business years. Glowing accounts of the prosperity of certain concerns who are blessed with business due to munitions and other war contracts have furnished an excuse for the unions to make demands on the ordinary building contractors, which, if acceded to, would practically put them out of business. If the men were content with an advance of wages without exacting the conditions that invariably accompany the demands for higher pay, the situation might be met, up to a reasonable limit, but it is the experience of the employers that the day's output falls off as wages advance, instead of increasing in something like the same proportion, or, at the least, being maintained at approximately a fair standard.

A movement is on foot in New London, Conn., looking to the formation of a Master Builders' Association.

Steps have recently been taken in Nashville to organize what will be known as the Tennessee Association of Builders' Exchanges, with James A. Daugherty of Nashville as president.

Want Los Angeles Contractors Licensed

The Master Builders of Los Angeles recently brought before the city council of that city a proposed ordinance, which is still under consideration, and which would require that all persons conducting a business of building and contracting shall register at the office of the inspector of buildings; the payment of a yearly license fee of \$100, and the furnishing of a \$5,000 bond to cover any violation of the building ordinance.

Convention of National Association of Builders' Exchanges

The next convention of the National Association of Builders' Exchanges will be held in Atlanta, Ga., on Feb. 13, 14 and 15 of the coming year.

The ninth annual convention of the National Association of Building Owners and Managers will be held at St. Louis on Sept. 12 to 15.

HOLE TO ADJUST HANGER
AND OIL BEARINGS

National Adjustable Storm-Proof Door Hanger

When you figure on a barn the prospective owner expects you to specify the material and fixtures that will make the best barn.

That's the reason it will pay you to be thoroughly posted on our No. 88 Adjustable Storm-Proof Door Hanger. It has two adjustment features, vertical and lateral—both simple and easily operated. Another distinctive feature is that the door is hung very close to the storm-proof rail.

Some time you will want a copy of our beautifully illustrated catalog. Better get it now; then you will have it when you want it. Your dealer's name will be appreciated.

National Mfg. Co., Sterling, Ill.

Asphalt Shingles Mean Larger Profits for Contractors

**Extra
Beauty
Without
Extra
Cost**

A HANDSOME, brightly colored roof of *Asphalt Shingles* makes a lot of difference in the way a house looks. Many roofings are so discolored and lacking in decorative effect that they add nothing to the appearance or character of a house.

Asphalt Shingles have a rich, permanent coloring that makes any home upon which they are used stand out among its neighbors. Their shades of red, green, gray, brown or black, with the smooth and regular outline of each separate *Asphalt Shingle*, make the roof an *ornament* to the house.

Asphalt Shingles

"Destined to Roof the Nation's Homes."

A roofing like this cannot leak and cause complaint from the house owner because it is triple-thick. Nor do *Asphalt Shingles* curl or blow up. They are very fire-resistant and give absolute protection against burning brands or sparks. Their long life makes them a perpetual source of satisfaction to the house owner.

Asphalt Shingles have these advantages, yet sell for practically the same prices as common roofings. Their quick-laying features, which save labor charges, mean that by using them you put yourself in position to get *more business* and so earn larger profits.

All of our advertising always refers the prospective house builder to his Architect and Contractor about Asphalt Shingles.

In Our Booklet "The Roof Distinctive" we tell still more interesting facts about them. This book is worth many dollars in the money-making hints it will give you, yet we will send it free if you write. We will also send new book of Fire Tests if you ask for it.

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Concrete Mixing Plant on Roof of Skyscraper

In carrying out an important piece of work in connection with an extensive addition to a large store building in the city of Chicago it was necessary to establish a complete concrete mixing plant on the roof of the structure. The building in question is nearly a block in length, extending to an alley in the center of the square, and is ten stories above the street level and three below. The building is of modern steel frame construction erected several years ago, and was designed to carry additional stories when the growth of the business of the concern occupying it should require them. Recently it was desired to construct an additional story at the south end of the building extending 176 ft. on State Street and 144 ft. on Van Buren Street, and a contract for the work was awarded to the Clark-Bisbee Company, 175 West Jackson Boule-

surface in the rear alley and provided with discharge gates designed to provide coal storage for the furnaces and which discharge the coal into a traveling bucket when required. It was decided to use several of these hoppers for handling the sand and stone in the new construction work. The material was delivered in six-ton auto trucks and dumped down the chutes into the hoppers, from which it was gated into wheelbarrows. The large elevator carried nine wheelbarrows and the smaller one five at each load to the tenth floor. An inclined runway was built from the tenth floor to the roof and all materials used in the concrete and in the new construction work were transported from the tenth floor up this inclined runway.

For mixing the concrete the contractors made use of a motor-driven "Standard" low-charging mixer of 8 cu. ft. capacity. This mixer was selected by reason of its light weight and great portability. It was taken

Fig. 1—View of Roof of Skyscraper in Chicago Showing Concrete Mixing Plant

vard, Chicago. The street walls of the present building extend a considerable distance above the roof, so that it was only necessary to erect a new roof and floor with the required columns, beams and girders. The new construction is entirely of reinforced concrete and the contractors decided that this could be handled to the best advantage by placing the mixing plant on the present roof of the building. The picture presented in Fig. 1 shows the appearance of the work while in progress.

The equipment of the building included two large high-speed freight elevators running from the third basement to the tenth floor, and one of which was of 10 tons capacity. In the third basement or, as it may be termed, the third story below the street level, were several elevator hoppers connected by chutes with the

up on the large elevator to the tenth floor and then up the runway to the roof, 180 ft. above the street level. In this work the columns, girders, beams and roof were constructed, after which the old roof underneath was removed and replaced with a reinforced concrete floor. There were required for the work 95 concrete beams, 22 concrete girders, 14 concrete columns and in the construction work there were used more than 13 tons of reinforcing steel rods, many of them 28 ft. long; also about 40,000 ft. of lumber for the "forms." The concrete was a standard 1:2:4 mixture, the coarser aggregate being crushed limestone screened to a ½-in. mesh. Due to the excellent facilities for handling the material, the work progressed rapidly and with apparently little more difficulty in handling the concrete than when mixed at the ground level.

New Stanley Barn Door Latch

A new barn door latch embodying a number of features likely to interest the architect and builder is shown in Fig. 2 of the illustrations. It is built around the idea of durability, its few parts being heavy and strong. Its construction is such as to protect the parts against rust, the bolt being tinned, the spring

Fig. 2—The New Stanley Barn Door Latch

sherardized and the handles, plates and strikes heavily coated with japan. The latch is also furnished galvanized when so desired. The angle slant on the strike and the bevel on the bolt allow the latch to lock automatically. It is easily operated from either side of the door by means of a roomy, comfortable handle. It is adjustable for doors all the way from $\frac{3}{4}$ in. to $1\frac{3}{4}$ in. thick. The bolt is wrought steel, solid at its working point, and has a throw of $15/16$ in. A pull on either handle slides the bolt back. The two handles are connected by a steel bar $\frac{1}{4}$ in. thick. An inspection of the illustration shows how the inside plate is applied well back from the jamb so that there is no danger of injuring the hand. This inside handle may be omitted if desired and the latch converted into an extra heavy catch. The strike is made wider than the bolt so as to allow for any sagging of the door. This new barn door latch has just been placed upon the market by the Watrous-Acme Mfg. Co., Des Moines, Iowa, whose sole sales agent is The Stanley Works, New Britain, Conn., and with New York office at 100 Lafayette Street. The latch is packed $\frac{1}{4}$ dozen in a carton with $\frac{3}{8}$ in. No. 10 screws, one pair of Safety Padlock Eyes, and full directions for its proper application.

"Perfect Art" Metal Ceilings

Artistic thought and adaptability of design to material are manifested in "Perfect Art" Metal Ceilings, which is the title of Catalog No. 16, issued by the James H. Watson Co., Bradley, Ill. The company directs special attention to its new line of Gothic and Colonial designs, also the improved Re-pressed Beads and Die-cut Nail Holes. The beads and buttons of all plates are now re-pressed on Tool Steel Dies, so

that every bead and button is exactly alike and fits accurately over the underlapping bead and button, thus producing a tight and perfect joint. The metal is cut out at each nailing point so that nails can be driven through the points, where the corners of the plates fit together, without extra effort. The result of these improvements is claimed to be decreased cost of erection. Halftone engravings, the majority of which are nearly full page size, illustrate the catalog and depict Ceiling and Wall Plates, Cornices, Profiles of Cornices and Mouldings, Centers and various designs of styles such as Louis XIV, Colonial, Gothic, Italian Renaissance, Romanesque, etc., together with their prices. There is also included directions for applying the ceilings over plaster or wood lath, prices and "How to Figure Quantities and Prices."

A New Dixon Pencil

Builders are sometimes confronted with a brick wall of decidedly porous material, which after a hard storm is wet enough to damage material in contact with it on the inside. The remedy applied some years ago to the First National Bank Building of Jersey City, N. J., will therefore interest many. The building is exposed to the salt air from the North River and also to all the driving storms from the East. The wall was painted with Dixon's Silica-Graphite Paint made by the Joseph Dixon Crucible Co., Jersey City, N. J., which rendered the walls impervious to moisture. Draftsmen, architects and others who use high grade drawing pencils will be interested to learn that the company has added a new pencil to its well-known line in the "Eldorado," the "master drawing pencil," furnished in 17 grades. It is claimed to have a strong, long-wearing, smooth and evenly graded lead. We understand that full-sized samples will be sent by the company when requested on the letterhead of any reader of THE BUILDING AGE and addressed to "Department 190-J." It is interesting to note in "Graphite" that two additions are being made to the plant of the company.

Universal Telescoping Casement Adjuster

A new telescoping adjuster for use on windows opening either in or out has recently been placed on the market by the Pacific Hardware Mfg. Co., Los Angeles, Cal. This adjuster is called the "Universal" and a view of it is shown in Fig. 3. It has a new tension grip operated by a thumb screw, which, it is said, can

Fig. 3—The Universal Telescoping Casement Adjuster

not slip out of place when once adjusted and is made of solid brass with any standard finish that may be required.

Fireplace Fixtures

The fireplace is undoubtedly an important adjunct of the modern home and one of the perplexing parts of its construction is the correct width of throat. It stands to reason that efficiency and economy are promoted by the use of a damper, for the one sized throat is certainly not at its best under all conditions. A damper is just as useful in connection with a fireplace as with a stove. The claim is made that Stover Improved Dome Dampers permit the throat width to be changed according to weather conditions and as the fixture forms and proportions the throat itself, there

MEDUSA WATERPROOFING

Bungalow of W. D. Shoupe, Chicago Lawn, Illinois
Made Weather and Damp-proof by Medusa Waterproofing

How About Your Waterproofing?

WHEN you are building concrete and stucco houses for *permanence*, there's one thing you must not overlook—and that is waterproofing. A builder is known by the houses he builds—and any number of contractors are building enviable reputations for themselves by making their houses weather-proof, storm-proof and damp-proof by the use of

MEDUSA WATERPROOFING

Medusa Waterproofing cuts down the cost of your concrete work. In stucco, it prevents hair cracks and checking—and *absolutely keeps the water out*.

It makes basements damp-proof—and keeps them that way *permanently*.

Best of all, Medusa Waterproofing is a time and money saver. It comes in powder or paste form—and only eight pounds is required for every barrel of cement used in the mix. Furthermore it won't affect the strength, setting, or hardening qualities of the concrete.

Do You Want to Know More about Waterproofing?

If you do, fill out the attached coupon and mail it to us today. We'll send you the Medusa Waterproofing booklet that is chuck full of interesting information which you can put into practical use. Fill out the coupon now.

is little opportunity for the mason to go astray when it is used. Many people like to avoid the dust and dirt incident to a fireplace by having it provided with an ash trap door, which permits the ashes to be dropped through the floor to the basement. In Catalog 1590 a new publication of the Stover Mfg. & Engine Co., 747 East Street, Freeport, Ill., these contrivances are described and illustrated by halftones and cross-sectional views of the fixtures in place. After the fireplace itself is constructed, there is an opportunity for modern equipment to facilitate the fire-building. Andirons of many styles, fire baskets, grates, spark and fire guards, screens, fireplace sets, wood holders, gas logs, etc., are all illustrated and described in the catalog under review. Prices are also given. The catalog shows a number of additions to the company's line.

New Baseboard Warm Air Register

Baseboard registers in connection with warm-air furnace heating systems are rapidly growing in popularity and in Fig. 4 we present a register of this type, which has recently been brought out by the Hart & Cooley Co., New Britain, Conn. The register is made in a variety of sizes which are classed as Nos. 141, 142½, 143, 143½, 144 and 145, the right-hand figure in every instance being the size of extension beyond the face line of the riser with which the register may be connected, giving a very large boot opening into the bottom. An important feature of the construction is that it is made in two pieces—the frame proper,

Fig. 4—New Baseboard Warm-Air Register

formed from a solid piece of metal, and the convex quick detachable face. For convenience in setting there is provided a steel gage, as shown at the bottom of the illustration, with a heavy black appearance, and above is the frame mentioned and in front of it is the detachable register face. The latter, as may be seen from the pattern, is intended to give a free air space equal to the largest boot with which it may be connected. The valve is of a single flat piece and arranged to be operated by hand or by the foot. The register box flanges of sheet metal may be turned over the edge of the register frame, making a tight job to prevent the leakage of air at points which would leave dust streaks on the wall. The detachable face may be removed by turning a rivet screw half a turn. Another point is that the distance between the open lattice work and the floor is sufficient to prevent annoyance from dust or dirt being swept into it in cleaning a room.

The "Ja-Nar" Automatic Room Temperature Regulator

Modern hygiene recognizes the value of an equable temperature in preserving health and human efficiency. Colds and many other ills are directly traceable to the sudden violent changes that often occur in the average home. A temperature regulator that can be applied to one radiator or many, that can be used in any one room of the house in which regulation of temperature is especially desired without going to the expense of putting in a complete temperature system and one that

will keep the temperature constantly at any desired degree between 60 and 80 deg. is certain to meet a demand that has been felt by many. Such a device, it is said, is the "Ja-Nar," described as "an automatic device for maintaining uniform room temperature" in buildings heated either by steam or hot water. It consists of a cabinet-looking covering made of furniture steel and fitting over the radiator, the size of which it closely approximates. The temperature is regulated by louvres which control the amount of air passing over the radiator so well that, it is said, the temperature will not vary more than one degree each way from the degree at which the device is set. The louvres are controlled by a "sylphon." This contains a metallic bellows inside of which is a volatile liquid which when heated gives off a vapor like steam and has a powerful expansive force. This liquid is said to be sensitive to very slight changes in temperature, never evaporates or changes form and therefore never needs renewal. The "Ja-Nar" is described and illustrated at length in a booklet entitled "The Ja-Nar" and the Sylphon Regulator is illustrated and described in "Ideal Sylphon Heat Regulators," both of which are being sent out by the Annex Co., Knoxville, Tenn.

"Northwestern" Concrete Mixers in Canada

A very gratifying demand for their concrete mixers is reported by the Northwestern Steel & Iron Works, Eau Claire, Wis. They state that these inquiries are coming not alone from domestic sources but also from

Fig. 5—"Northwestern" Concrete Mixers in Canada

Canada. A recent shipment to the Canadian Government consisted of Model 610, which has a capacity of 12 cu. ft. and weighs 6000 lbs. It was ordered to be sent by express—an indication of the anxiety of the Canadian authorities to get the machine at work as quickly as possible on permanent improvements for their largest concentration camp. Many "Northwestern" mixers are in use across the border and one of the popular styles owned by a prominent contractor of Montreal is shown in Fig. 5. All this is suggestive of the manner in which the "Northwestern" has made friends with Canadian contractors.

Catalog of Berger's Sheet Metal Products

An attractive publication of 184 pages neatly printed in black and red on white enameled stock and with a cover of heavy gray stock carrying a design on the front which typifies the steel industry, has just been issued from the press by the Berger Manufacturing Company, Canton, Ohio. It is known as catalog No. 10 and is regarded by the company as one of the most complete works on sheet metal products which it has ever issued. The company turns out a diversified line of sheet metal goods, among them being flat sheets, roofings and sidings, tin and terne plate, eaves trough, gutters, pipe, etc., ventilators, skylights and special work, galvanized cornices, finials, tanners' accessories, steel ceilings, metal lath, rein-

Why are Wheel- barrows

Like Automobile Tires?

"People has got into the habit of measurin' the value of automobile tires by the number of miles they'll run, under certain road conditions, carrying a certain load.

"It's a good habit, if ye don't go too strong on the 'freak' performances the tire men talk about in their advertisin'.

"Now a feller ought to buy *wheelbarrows* on the same basis, pickin' out the ones that carries the heaviest tonnage the greatest number of miles, under the most contrary conditions.

"The costs and the profits on every job has got to be *measured by the barrow-load* of stuff carried. There ain't any other measure.

"Jest as there ain't any other measure for rubber tires except their mileage and the load they carry.

"All of which is another way of sayin' that the Barrow that piles up the most mileage and tonnage and days' work is the best investment.

"This means **STERLING BARROWS**, with their self-lubricated fiber bushings, their perfect balance, their out-and-out sturdiness, and long-lastingness.

"Take it from me, a cheap wheelbarrow, like a cheap automobile tire, is a pretty expensive thing for any man."

—TIM TRUNDLE.

Send for Our Catalog No. 19

Sterling Wheelbarrow Co.

Poster of the "Eveready" Saw Rig

The builder who has need of a saw rig in connection with his work will find much to interest him in a new poster issued by the Oshkosh Mfg. Co., 86 Buck Street, Oshkosh, Wis. Herein is described the Oshkosh "Eveready" Saw Rig and the appliances that can be affixed to it and which may also be attached to an old style machine at little expense. Halftone engravings of the machine and its attachments lend interest and include Rip and Cross Cut Saw, Jointer, Safety Guards for Jointer, Rabbeter, Mortiser, Horizontal and Vertical Boring Attachments, etc. The company is also sending forth a booklet entitled "Here Is the Evidence," which contains a long, though partial list of satisfied users of the "Eveready." There are also facsimiles of letters received from contractors, builders, etc., who commend the machine. Some of these letters describe interesting "kinks" or "wrinkles" which an inventive owner has utilized in connection with the saw rig.

New Butt for Accordion Doors

A butt especially designed for use on accordion doors is being placed upon the market by the Stanley Works, New Britain, Conn., and in Fig. 6 we present a general view of it. This style butt is offered both with

Fig. 6—View of New Accordion Door Butt

and without ball bearing washers, the latter style being equipped with the Stanley patented non-rising butt pin. When open, these accordion door butts have sufficient clearance to receive the combined thickness of the doors between the anchor door and the wall. The butts have a 3¼-in. throw, and may be used on doors of any thickness. They are particularly adaptable wherever a large offset is desirable. The butts are made in only one size, namely 2¼ x 6 in., and are packed one pair in a box, being furnished in any standard and Stanley finish.

Burt Manufacturing Co. Enlarges Plant

Owing to the great increase in its business, the Burt Mfg. Co., Akron, Ohio, has found it necessary to enlarge its manufacturing facilities, and is just completing two large two-story additions to its already good-sized factory at Akron. It is also purchasing considerable up to date machinery, for on account of the determination to enlarge its scope of business, much new machinery will be required, for which orders have already been placed. In the past the company has devoted its efforts exclusively to the manufacture and sale of exhaust heads, ventilators and oil filters, but in the future it proposes to branch out into a general line of sheet metal work.

Black Rock**

BLACK CENTRE

REGISTERED TRADE MARK

When You Build— Build Reputation

Building a reputation is a simple thing. All you need to do is to do what you have to do a little better than your competitor, and your fame grows apace.

The carpenters and builders who saw far enough ahead to interest themselves in Black Rock Wallboard, started then to build their reputations on a firm foundation.

The jobs that you do this year will either advertise you, or injure your

reputation, five years from now. If you use Black Rock Wallboard—in 1920 people will point to you and say “There’s a man who builds wisely and well.”

As a man who is used to dealing in lumber, you will like the way Black Rock Wallboard works. It is as stiff as lumber. Moreover, it is the only board with a moisture-repellant black center.

The last word in wallboard

The reason why Black Rock has such properties of permanence is simply that the veneer process of combining the four plies makes Black Rock the stiffest and strongest wallboard. Incidentally, that’s why it looks, works and lasts like high-grade kiln-dried finishing lumber.

Incidentally, that’s why it will not warp, buckle, bulge or pull away from the nails. The very fact that by this new method Black Rock has been moisture-proofed eliminates the principal causes of contraction and expansion.

And the well-sized, smooth, “sanded-like” surface of Black Rock needs less paint, because no priming coat is necessary.

Black Rock Wallboard is something *new, different*—the last word in wallboard.

It will boost your reputation as a builder. It will bring you “repeat” business. You cannot afford not to know about Black Rock. Send post-card, or coupon, for free book and sample.

Catalog of the Majestic Company

The Majestic Company, Huntington, Ind., has recently issued a new catalog of Majestic modern building specialties. Illustrated and described are round Majestic hot-air heaters, square heaters, the Majestic "Duplex" system of heating, side wall and stack branches, first floor and second floor side wall and stack fittings, "Minneapolis" heat regulator for hot-air furnaces, Majestic coal chutes for residences and store buildings, the Majestic burglar-proof basement window, porch column bases and several types of built-in and underground garbage receivers.

Importance of Proper Crating of Goods

The Kohler Co., Kohler, Wis., manufacturers of enameled plumbing ware, has given considerable study to the problem of crating bathtubs, lavatories and sinks. A special crate has been devised for each piece of ware, a crate that is exactly adapted to it. one that will save space and weight and is economical in every respect. This becomes an important matter where rents are high and room, either in warehouses or plumbing establishments, is scarce.

Another feature that makes Kohler packing of advantage is the protection which it gives to the product. The crates are strong but light in weight, while adequate padding is an additional safeguard against damage.

Even the small ware, such as sinks, sink backs and drainboards, is packed in individual crates which are bundled together when shipment is made in lots. This allows the dealer to reship a single piece without the inconvenience or cost of recrating, while it does not demand an increase in storage space.

New Moulding for Wall Board

That wall board is effective and economical as an interior trim is evidenced by its rapidly growing popularity in all parts of the country. Its merits have been set forth from time to time in these columns and for several months past a most interesting serial relating to it has been published. With a view to facilitating the installation of the material, the W. R. Friedel Co., Memphis, Tenn., has devised what is described as the Friedel patent flange moulding, which represents the result of many years' experience with wall board and a thorough familiarity with the usual methods of applying it. Full details regarding the new moulding are to be found in an attractively printed booklet entitled, "The New Way." Crooked or irregular spaced studing, warped joists and various inaccuracies in framing work are claimed to cause no trouble when this moulding is used, for it is said to be entirely independent of headers and studs, the flange itself providing a suitable base for the wall board. The latter slips into grooves or flanges and is not nailed, so that expansion or contraction of the wall board will cause no trouble. Removal of the wall board is said to be easy at any time without its being injured. The elimination of nailing and extra framing and fitting of headers is said to materially reduce the cost of labor and practically offset the slight difference in price between the Friedel patent moulding and the ordinary kind. The material is provided in 10, 12, 14 and 16-ft. lengths in yellow pine, but special forms to detail can also be furnished in oak, gum, birch or mahogany. The booklet under review contains drawings showing the moulding and its manner of installation, halftones of houses and their interiors in which the material has been used, and other information likely to be of value to the carpenter and builder interested in wall board installation.

Motor Trucks vs. Horses

Many times during "hot spells" of the past few weeks the contractor or builder using a horse in connection with his business has probably had many opportunities for considering how unfavorably it compares with the

position.

From time to time, other Iron Planes, made in imitation of this celebrated plane, have appeared upon the market.

These imitation Planes are often put up with numbers and labels designed to make the consumer think that he is obtaining the "BAILEY" Plane.

We are the sole manufacturers of the "BAILEY" Plane. Every Plane has the name "BAILEY" and the number cast in the bottom, and the name "STANLEY" is stamped on the cutter.

Always insist that your order be filled with Planes made by THE STANLEY RULE & LEVEL CO., which carry with them a GUARANTEE backed by a company that has been manufacturing Carpenters' and Mechanics' tools for over half a century.

STANLEY RULE & LEVEL CO.
NEW BRITAIN, CONN. U.S.A.

motor truck. On the other hand, when the thermometer directs its energies to keeping as low as possible, the slipping and falling of the horse makes it equally inefficient by comparison. That the motor truck is superior in weather more favorable to the horse is also generally conceded, and many builders are availing themselves of the machine's capacity for work. Information that will prove of interest to those contemplating the motorization of their equipment is contained in the last issue of *Traffic News*, the house organ of the Federal Motor Truck Co., Detroit, Mich., which is also sending forth a folder entitled, "Federal in Picture." This folder contains interesting halftone engravings of various unusual occupations in which "Federalers" are engaged, such as street sprinklers, buses, etc., together with pictures of men prominent in the company and illustrations showing the growth of the plant. It is said that the first Federal truck made is still in a healthy state of working efficiency.

TRADE NOTES

Small-sized stucco houses seem to fill a need felt by many who desire a low cost dwelling of partial fireproof construction and which will require little or no expense for upkeep. Houses of this type are illustrated in a recent issue of *Expanded Metal Construction*, the house organ of the North Western Expanded Metal Co., 904 Old Colony Building, Chicago, Ill. The advantages of stucco, together with information concerning its application to this style of house, with or without sheathing boards, is contained in an article entitled, "The Small Stucco House." There is also a report of building conditions in different sections of the United States.

Prompt service and dependability are among the things emphasized in the August issue of *Door-Ways*, the house organ of the Richards-Wilcox Co., Aurora, Ill. The company states that it aims to supply the best in this direction and its Engineering Department is always ready to help solve any technical problem which may be submitted. There is also an article on garage doors which is of interest in cases where one or more trucks are to be housed.

The Flintkote Manufacturing Company, 98 Pearl Street, Boston, Mass., has issued a card containing samples about 2 in. square of its shingles. There are samples of slate surface and Rextile shingles in their various colors; Rex canvas roofing; valley and ridge strips; Rex Flintkote roofing; Rex black waterproof paper, etc.

The Highwood Dumbwaiter Company, Park Avenue, Leonia, New Jersey, has just issued a neat four-page folder giving brief specifications of its "Highwood" dumbwaiter. The claim is made that the material is all ready for erection and it is of such a nature that the dumbwaiter can be installed by anyone able to intelligently use a hammer. For shipment purposes the dumbwaiter car is used as a container for the ropes, hardware, machine, etc., thus reducing the cost of freight to a minimum.

Valuable advice for securing painting contracts from farmers is contained in the "Farm Painting Number" of the *Carter Times*, published every once in a while by the Carter White Lead Company, Chicago, Ill. There is also an article on how to break up white lead quickly, easily and smoothly, together with a practice estimate for calculating the amount of paint and labor necessary to cover a given area and the overhead expense, etc., which must be added if a profit is to be made.

The increasing popularity of concrete in the construction of country residences lends decided interest to the half-tone engravings of houses built of that material which are contained in the July issue of the *Medusa Review*, the house organ of the Sandusky Cement Co., 624 Engineers Building, Cleveland, Ohio. Other interesting material is also contained therein, including the description of how a St. Louis flat building was converted into a café and restaurant, Medusa

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

Simplicity

WE believe what you want is a simple Store Front construction—one that you can readily understand how to install or turn over to your carpenters to install and feel sure it will be a good job.

Almetal

Back in '89—27 years ago—we began building Store Front construction. We've never built a "freak"—never attempted to sell you a novelty. By our experience we feel able to serve you as you desire and to prove a source of economy. Heavy gauge copper used and "ALMETAL" sash efficiently ventilates show windows. See "ALMETAL" details—a card will do—no obligation.

The Pamphlet and the Mounted Model Hanger will be mailed on request.

SOMETHING FOR US.
We ask your special attention to items 5, 6, 7 on page 5 of the Pamphlet and to the matter on pages 23 and 24 relating thereto.

THE W. J. CLARK CO., Salem, Ohio, U. S. A.

White Portland Cement helping to complete the transformation.

The annual outing of the employees of the Simonds Mfg. Co., Fitchburg, Mass., was held at Lake Dennison on Aug. 5, and the festivities were enjoyed by over 500. There were various sporting events besides the wood-sawing contest, in which, of course, Simonds cross-cut saws were used.

Manufacturers and others who are giving consideration to export opportunities will be interested in an announcement made to-day by Messrs. Gaston, Williams & Wigmore, Inc., 140 Broadway, New York City, that their Far Eastern Division, organized and equipped to develop markets for America's industries, will hereafter be in charge of Messrs. Joseph J. Keegan and Hilliard J. Rosencrantz as their managing directors. Keegan and Rosencrantz have been prominently identified with American trade development in the Far Eastern countries for the past sixteen years, representing American manufacturers.

The Union Investment Company, home builders, located at 5122 West Stevens Street, Seattle, Wash., are about to erect a number of buildings, including several residences, and are in the market for building materials and equipment of all kinds. The company would therefore be glad to receive catalogs and samples from manufacturers of materials of this character.

A late issue of *The Dutch Boy Painter*, which is devoted to the interest of good painting and published by the National Lead Company, New York City, contains a great deal of interesting information which the builder as well as the painter cannot fail to appreciate. There is an article on the care of brushes, and another on painting stucco houses, the latter being especially valuable by reason of the extent to which stucco houses are being erected at the present time.

Architects and building contractors will find interesting material in the booklet of 100 pages issued under the title of "The Cement Gun," by the Cement-Gun Co., New York City. A description is given of the apparatus, process and product, and in connection therewith are a large number of photographic views showing the machines and their work. The booklet shows how concrete can be repaired, old frame buildings covered with cement, steel columns rendered rustproof, wooden piles made waterproof and protected against the inroads of teredos and limnoria—all by the "cement-shooting" of the "cement-gun."

Bird & Son, Dept. B, East Walpole, Mass., are distributing among architects and builders an attractive pamphlet, portions of which are printed in colors and relating to Neponset shingles, wall board and roofings. Illustrations for the most part are halftone engravings, but among the line drawings are several reproduced from the serial article running in *THE BUILDING AGE* on the use of wall board for various purposes. The make-up of the pamphlet is neat and attractive, and a copy of it will be sent to any reader who may make application for it.

Ed. H. Witte, a Kansas City engine expert, has just prepared a clever little book on engines that is likely to appeal to every carpenter-contractor, builder or others operating wood-working shops requiring the use of power. He states that he will be glad to furnish to those requesting it a copy of the book as long as the supply lasts, it being issued under the unique title of "Why." Anyone wishing a copy has only to write the word "Why" with his name and address on a postal card and send it to Mr. Witte, 3190 Oakland Avenue, Kansas City, Mo.

The Stowell Manufacturing Company, Jersey City, N. J., are increasing their facilities by the erection of a one-story reinforced concrete office building. The demand for the prepared asphalt roofings, asphalt shingles, etc., turned out by the company is constantly growing and the improvements noted have become imperative.

Expanded Metal Engineering Company, 101 Park Avenue, New York, is distributing among carpenters, builders and contractors a pamphlet containing that portion of the new building ordinances of New York City relating to the use of steelcrete mesh. Hereto-

CLIPPER TOOL CO., 286 Mills St., Buffalo, N. Y

fore in order to use any type of reinforcing in cinder-concrete construction in New York City, it was necessary to have a load test of the system made subject to the approval of the Building Department. Under the code recently adopted the above method of procedure has been abolished and a new method of computation has been devised whereby the allowable capacities of floor slabs may be determined without resorting to tests.

The Vinton Company, for some sixty years, associated with the building interests of Detroit, Mich., announces that it has withdrawn from construction work and contracting and will devote its activities hereafter to operations of an investment nature chiefly along real estate and building lines and including the financing of construction work.

The architectural firm of Perlstein & Perlstein has recently opened a branch office at 2517 Surf Avenue, Coney Island, N. Y., and will be glad to receive catalogues and samples from manufacturers of building materials.

Detroit Steel Products Company, Detroit, Mich., has just built two new concrete buildings to be used for the manufacture of Fenestra solid steel windows, these improvements increasing the capacity of the works approximately 100 per cent. Prospects for 1916 indicate that the year will show a gratifying increase over 1915, and the management of the company is therefore increasing the facilities to meet the demand.

The California Redwood Association, of San Francisco, Cal., has recently issued an attractive booklet containing matter which cannot fail to prove of value to any builder contemplating the use of redwood. In addition to calling attention to the many advantages claimed for this wood the booklet contains a large number of colored plates giving, as faithfully as the printer's art will permit, exact reproductions of redwood panels treated with different finishes, together with full directions for the treatment to produce these effects. There are a number of illustrations of fine homes finished in this wood, the buildings being located in all parts of the United States. The Redwood Association is installing an elaborate exhibit in the Pacific Building in Oakland, Cal., and is also sending out a great amount of other literature of interest to builders and contractors.

Henry J. Bacon, for fourteen years in charge of cabinet work at Morehouse Bros. Company, has just started in business for himself at 113 Columbia Street, Meriden, Conn. He will make a specialty of all classes of carpentry work.

Doesn't It Stand to Reason?

If you have a bracket with two strong legs wouldn't you expect it to be steadier than another bracket with only one leg? Sure you would. That's why you have a right to expect the "Trouble Saver" Brackets to be stable and firm. And they are. Note how the legs brace against each other at the outer ends, thus preventing all side motion.

Another thing you will like about the "Trouble Saver" Brackets is the speed with which you can erect them. No bolts, no nails, no nuts, not a screw. Up go as many "Trouble Savers" in five minutes as wooden scaffolds in five hours.

You can prove their worth in short order. Send your name and let us tell you about our thirty-day free trial offer.

Carpentry Books SHIPPED FREE!

Don't take our word for it that these are the most complete carpentry books ever written. Get them into your home or shop—free—and determine their value for yourself. Send the coupon to-day—now—and the entire eleven volumes will come to you at once, express prepaid. If, after a full week's trial, you decide to keep them, you can buy them at half the regular price and on the easiest of easy payment plans.

New 1916 Edition **Cyclopedia of Architecture, Carpentry and Building**

consists of ten large volumes, handsomely bound in half morocco, gold stamped, containing 4,760 7 x 10-inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross indexed for quick, easy reference.

PARTIAL TABLE OF CONTENTS

Mechanical, Freshand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

Plan Book and Consulting Service FREE

We give free to every purchaser of our **Cyclopedia of Architecture, Carpentry and Building**, a copy of "Modern American Homes," a complete and up-to-date plan book. Contains plans and specifications for 168 structures, including excellent exterior and interior views, detailed estimates, etc. Designed by leading architects, it covers city, suburban, and country homes; bungalows; summer cottages; tent houses and camps; apartment houses; garages, and public buildings. 224 pages, 9 1/4 x 12 1/2 inches, and 426 illustrations. Printed on enameled paper and substantially bound. With this plan book in your shop you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect—you can offer him his choice of practically every type of home. This saving of the usual architect's fee should get you the business.

In addition we give free with each set a year's consulting membership in the **American Technical Society**. Through this service you have the assistance of a staff of architectural and building experts. These men are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

Send for this great combination today

We will send the complete eleven volumes to your home for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet your expectations they may be returned at our expense. If you keep them send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80—regular price \$50.00—has been paid. Remember—the consulting membership and plan book are included absolutely free.

Can you afford to let \$2.00 a month—50c a week—stand between you and success? The consulting membership alone is worth many times the first cost of the books. Fill in and mail the coupon—NOW!

American Technical Society, Chicago, U. S. A.

At Last! A Practical Home-Study Course for

CARPENTERS

FOREMEN—SUPERINTENDENTS—CONTRACTORS
and all other men in the Building Lines

Plan Reading, Estimating,
Architectural Drawing, Contracting, etc.

This is a course for practical men. We send you actual blue print plans of buildings now being built or recently completed. Practical training, not book knowledge, is what you want—it's what we give. When you think of the opportunities this training offers, you will take time—right now—to mail the coupon for full information.

To Succeed In any branch of the building business you must have a complete knowledge of plans and specifications. You must be able to estimate closely the cost of material and labor. Guessing won't do—you must know. This knowledge is what makes successful foremen, superintendents and general contractors. This knowledge means money—thousands of dollars—to any builder—to you!

Your spare time is enough. You can master these subjects in your own home by this new, easy, quick method.

This elegant set of Drawing Instruments and Complete Outfit furnished FREE to our Students.

Special Trial Offer!

For only \$2 we will send you the complete set of working blue print plans for a large residence just completed in Evanston, Ill. Also the complete specifications for this job. We will also include questions concerning the plans and a complete itemized estimate showing how to figure the cost of the building down to the last penny. This is information worth many times its cost to you. Supply of plans on this offer is limited and will not last long. Send for your set today.

The Trolley Track

Long use and years' experience have proven the box-shaped trolley track No. 31 and No. 35 types the most satisfactory.

This type track provides two runways on which the carrier wheels roll, thus distributing the load; protects the hangers from the weather, is bird-proof, jump-proof and trouble-proof.

Sold in 4, 6, 8 and 10-foot lengths.

The Hanger

From a mechanical standpoint, the perfect design for a door hanger is the center hung type—used only in No. 31 and No. 35 types trolley track.

The four hanger wheels roll in the two smooth runways in the track; from the exact center of the two axles, which connect the four wheels, a pendant suspends to which the aprons which hold the door are attached. Thus the load is suspended from the exact center of the hanger—any variation of the door off center of gravity does not affect the easy movement of the hangers on the track.

Why not give your clients the best when it costs no more?

LOOK INTO

Trade Mark Reg. No. 94745

—you'll never find another building material or wall lining like this—none so flat and strong, with so slight a tendency to warp or shrink, none so easily handled, sawing so clean and smooth; none so durable; none with such a stubborn resistance to air, cold, heat, moisture and fire. None so adaptable to so wide a range of uses.

Compo-Board has all of these features as a result of its patented wood core construction.

How important it is then that you get Compo-Board when you ask for it. You can't be fooled if you look for the wood core, for it is easily and quickly identified.

You can get just the amount you need for any job in strips four feet wide and in even lengths up to 18 feet long.

Sold by dealers everywhere. Write for interesting book and free sample piece.

The Compo-Board Company
5778 Lyndale Avenue No.,
Minneapolis, Minn.

DUTCH BOY WHITE LEAD

is pure lead reduced to paste form—white but readily tinted. Indispensable to good painting.

Sold in 12½, 25, 50 and 100-pound, black, steel kegs. Look for the Dutch Boy guaranty label and the words "Dutch Boy White Lead" in orange on the sides.

The Answer to the Outside Painting Problem ZINOLIN

NAME the most difficult-to-meet requirements you ever made of any paint before using it or specifying it. Then, from the below list, see if Zinolin, the "Arnold-ized" Zinc, has not only met but exceeded any expectation you ever dared hold concerning a paint.

This Revolutionary Paint—

- 1—Permanently holds its luster.
- 2—Gives a whiter white than ever before known for outside.
- 3—Holds its colors absolutely fast.
- 4—Covers 30% more surface per gallon than white lead.
- 5—Does one coat work which quite often equals two.
- 6—Hides jet black with two coats of pure white.
- 7—Gives a tougher, more durable coat.
- 8—Does not crack, chalk, blister or peel.
- 9—Is easier and quicker to apply.
- 10—Breaks up easier than white lead, saving the painter's time.

The full facts are given in our LEAFLET and you ought to have this LEAFLET at once. Send for it now.

Keystone Varnish Co., 2012 Keystone Building
BROOKLYN, N. Y.

Makers of justly famous Keystone, the original washable wall paint.

The Wall

The wall is hollow—built like a thermos bottle—perfect insulation—warm in winter—cool in summer.

The Machines

Our 1916 Flexible Sliding Plate and Angle Iron Corner System insures absolutely plumb buildings with corners of any angle—the most perfect concrete building system in the world. The Van Guilder machines cut out one-half the labor. The steel reinforced walls cost no more completed than hollow blocks cost before they are laid.

Get the Big End of the Building Business

Think what it would mean to you if you were equipped to build concrete houses for only a little more than your competitor charges for building wooden houses. Think what it would mean to be able to do this without continually buying lumber for wood forms or having a car load of old-fashioned steel forms to take care of and move from job to job. Buy the

Van Guilder Hollow Wall Machines

A machine builds a course of hollow wall 9 inches high at each operation, using semi-wet mix. It is then moved ahead and filled again. When the job is done, you have a house within a house, the two walls being completely separated by a blanket air space. The machines have been used successfully in all parts of the country on big and little construction. It is remarkable the amount of wall you can run up in a day with the forms that you can carry on a wheelbarrow. Write for booklet containing full details.

STEWART

TRADE MARK

FURNACES and RANGES

Stand Upon a Reputation of
84 Years' Honest Service.

The best architects and builders recommend Stewart Furnaces because it is safe to do so.

It is safe for the seller because there is nothing about a Stewart to be afraid of, nothing to be ashamed of, and it provides a good profit.

It is safe for the buyer because it heats with the one healthy heat, constantly changing warm, fresh air.

It will give undiminished good service for many years and will eventually pay for itself by reduced fuel cost.

When you specify a Stewart Range you make a life friend of the housewife because its baking oven has

been famous since 1832.

The up-to-date models are everything a stove could be, everything a stove should be. They possess many labor saving, fuel saving, time saving and money saving devices.

And there is a sufficient variety of designs to satisfy any demand as to style for coal or combination coal and gas or wood.

Your special attention is called to The New Service Stewart Combination Coal and Gas Range.

Write today for booklets, terms, etc., on Stewart Furnaces and Ranges

Prepare for Winter *but don't put up the old stove*

The HESS Welded Steel Pipeless Furnace. No horizontal pipes nor air ducts in cellar.

The Hess steel furnace is sold direct to contractors and consumers, but is not offered through dealers nor agents. Specially low prices, therefore, are possible, and very many contractors throughout the United States are purchasing Hess furnaces for themselves and for their clients. Installation is easy, not requiring the services of special mechanics.

THE HESS PIPELESS FURNACE supersedes the base burner, costs no more, uses less fuel, circulates the heat better than stoves or radiators. The entire furnace is enveloped in a down-flowing current of cool air, which returns, heated, to the rooms. Therefore, every particle of heat is used and none is wasted. There are no horizontal pipes nor air ducts, no muss nor dirt upstairs; easy to install and requires little space in the cellar. Suitable for bungalows, churches, stores, etc., but not recommended for two-story houses, for which we supply our regular *pipe* furnace, with separate pipes and registers.

Write for complete illustrated booklet and special contractors' rates.

Cut-Out View UNDERFEED Furnace

Let It Work for You

The Williamson *New-Feed* UNDERFEED will make a friend for you of every person who purchases it through your recommendation or specification. The reason is that it will save $\frac{1}{2}$ to $\frac{2}{3}$ on coal expense.

It will create business for you because the news of its money saving efficiency will spread far and wide, bringing you inquirers who can be turned into customers.

And the UNDERFEED advertises you because you can make the startling guarantee that it will cut coal bills $\frac{1}{2}$ to $\frac{2}{3}$. A million dollar corporation backs that guarantee—you risk nothing.

WILLIAMSON CUT
NEW-FEED COAL
UNDERFEED BILLS
Furnaces and Boilers $\frac{1}{2}$ to $\frac{2}{3}$

Over 35,000 enthusiastic users can tell of better, cheaper heat, the UNDERFEED Way. Builders, contractors, and architects everywhere are cashing in on this nation-wide approval.

The UNDERFEED has succeeded because it burns the cheaper grades of coal without smoke, gas, dust, smell, or clinkers. Fuel is fed from below; fire is on top, free to play right against the radiating surfaces, and not smothered by half-burned coal. Adapted to warm air, steam, hot water, or vapor.

The coupon below brings our special data for contractors, builders, and architects. Send now; you'll be interested and pleased.

The Only Tapered Asphalt Shingle

Winthrop Tapered Asphalt Shingle

Just ask for a sample shingle. See how tough, how pliable and how durable it is. See how it is made like a wooden shingle—thick at the butt and thin at the top. See how easy to lay it is. See what a beautiful roof it will make—red, green or slate-black. Then you will understand why owners want the Winthrop when they know about it.

Winthrop Tapered Asphalt Shingles will enable you to get most of the roofs in your town. They win out with less argument than anything you ever tried to sell, for they look better than wood shingles and they have all the protection of asphalt.

House & Garden Is a Real Help

because it is a practical tool for the homemaker. It is the final authority on the thousand and one problems of house building, furnishing, gardening, sanitation and the like which at one time or another puzzle the owner of every house.

Everything for the House

Everything for the Garden

Everything for the Grounds

Hundreds—often thousands—of dollars may depend on a single decision, and expert advice prove invaluable. May we suggest that

\$1 Invested in House & Garden

a tiny fraction of your loss on one ill-chosen chair

Will Save You \$100—

Perhaps \$1,000

Consider, then, that by the simple act of mailing the coupon below and at your convenience forwarding \$1—a tiny fraction of your money loss on a single ill-chosen chair or discarded set of hangings—you insure your having expert advice on all your house and garden problems for the coming autumn, winter and spring.

Not only will you have before you now—when you are spending hundreds of dollars on fall furnishing and refurbishing—House & Garden's great Autumn Furnishing and House Planning Numbers; but you will also have the benefit of its guidance in your spring garden planning and planting.

No matter what your income, House & Garden will tell you how to expend it most wisely, because:

It covers house, garden, grounds. Every department of the home—interior, exterior, garden, garage, stable, grounds—is discussed.

It assures absolute good taste. Trained experts and artists edit House & Garden. Its artistic authority is unquestioned.

It appeals to all incomes. The family with \$1,000 a year for house expenditures and the family with \$100,000 alike find it a responsible guide.

It saves mistakes and money. Through its expert advice you save money by saving mistakes—and house mistakes are often very costly.

It gives prices and qualities, so that you can determine the value to you of everything in its pages.

Its Information Service is at the command of all readers. Questions on everything relating to the home are answered without charge.

Its Shopping Service—also without charge—is maintained for those too far away or too busy to shop for themselves.

Its artistic quality is equal to that which has made Vogue and Vanity Fair celebrated everywhere among people of good taste.

Its staff of consulting experts is at your service. Connoisseur, architect, kennel expert, landscape gardener, interior decorator, sanitarian, saleswoman and friend are all packed between the covers of House & Garden.

It costs only \$3 a year—a tiny fraction of your loss on one ill-chosen rug or chair.

Special Offer—Six Issues for \$1

TO CONVINCE YOU that House & Garden is personally valuable to you, we will send you the next six numbers for only \$1—you see, you save 50c, for the annual subscription is \$3—if you fill out and mail us the coupon *now*. These six numbers comprise:

Fall Planting Guide House Planning Number
Christmas Gift Number Annual Building Number
Garden Planning Number Spring Garden Guide

If you have a garden, or are going to have a garden; if you own a house, or are going to build a house, you will find these six numbers full of positively invaluable advice and suggestion. One trifling dollar invested in them now will save you \$100—perhaps \$1,000. Mail the coupon now—before you forget or mislay this offer.

HOUSE & GARDEN, 440 Fourth Ave., New York City
Send me six numbers of House & Garden, beginning with the September (Autumn Furnishing) Number for which I enclose \$1 herewith (OR September, and I will remit \$1 on receipt of bill. (Foreign \$1.50. Canadian \$1.25.)

THIS is what
you buy—
not
THIS

You can't expect
Beaver Board results
unless this trade-mark
is on the back of the
Board you buy.

Both Beaver Board

In one case it's on the finished wall; in the other it's in the bundle. *You* are not interested in the bundle. Neither are *we*. We are both interested in the room—the final result.

We are not selling Beaver Board by the bundle but Beaver Board by *what it will do*—Beaver Board Service. The ordinary hit-and-miss brands of wall boards all look more or less like the standard Beaver Board—in the bundle but not on the wall. Defects in wall boards don't show up in the *piece* but in the *finished job*. Beaver board walls and ceilings last longer, stay flat, are more easily and more handsomely decorated. Summed up in a word—they satisfy.

That's the biggest asset you or we can have—satisfied customers.

That's why we put the Beaver Board trade-mark on the back of every panel. It's a guarantee of satisfaction.

BAYONNE

Economy

Bayonne will outwear any other prepared covering and tar roofing because it does not shrink or expand—never blisters or crumbles—is **absolutely waterproof**—and far less costly than copper.

BAYONNE

is Real Economy at all times. But at the present time, although the first cost may appear high, Bayonne is **Far Cheaper** than even the lightest and poorest of ordinary canvas, when you consider the extra labor and painting—with paint at \$2.50 a gallon.

Bayonne is laid on the dry boards—requires no filler and only one light finishing coat.

And any canvas filled and painted—no matter how well done—cannot come up to Bayonne.

Write for Sample Book "D" giving prices and laying instructions. See Sweet's, Page 426.

If Your Future Depended on a Single Penny—

you'd think a long time before you wasted that precious cent. Well, here's the other side of the story. Your future success is going to depend on yourself first of all, and on the training you have had. A penny postal sent to Gray's School of Sheet Metal Pattern Drafting will set you on the path which leads to success in the sheet metal trade.

Are you going to pass up this opportunity for a penny? Write today.

Gray's School

241-249 W. 39th St. New York City

Don't Divide Profits with the Plasterer!

Every fall thousands of attics are converted into livable rooms, either by the use of lath and plaster or by means of some substitute for plaster. In either case the carpenter is called to set the necessary supports. If he is awake to his own interests and to the interests of the owner, he recommends

CAREY
Ceil-Board
FOR WALLS AND CEILINGS
SUPERSEDES PLASTER

No sensible man will have his home mussed up with plaster when he knows that he can have his remodeling done with Ceil Board which is applied by the carpenter with hammer and nails. No housewife will consent to have her attic floors ingrained with mortar nor to wait for weeks while the plaster is drying when she knows that the carpenter can do a better job, with no dirt or delay, by means of **CAREY CEIL BOARD**.

There will be business of this kind in your community. Be prepared to handle it promptly. Send today for samples of Carey Ceil Board in plain and natural hard wood finishes.

The Philip Carey Company
1020 Wayne Ave.,
Lockland, Cincinnati, O.

Offices and Warehouses in Principal Cities

One hand does the work of four hands, when you roof with **Flex-A-Tile Style 4 Asphalt Slabs**.

One workman lays four shingles with one motion instead of four shingles with four motions.

No time is wasted in chalk-lining as when single shingles are used. **Flex-A-Tile Style 4 Asphalt Slabs** automatically space and gauge themselves. When laid they give the appearance of rectangular-shaped single shingles.

FLEX-A-TILE
Style 4 Slab

Flex-A-Tiles in slab form are recognized as the roofing industry's most important improvement in a decade. We make them in **Diamond Point Style** as well as the **Style 4** here pictured.

It's simply a matter of individual preference which style is used. Get samples of both styles.

Supplied in the two regular **Flex-A-Tile** natural stone colors of red and green.

We Want Good Agents

in every section of the country, to handle the **Flex-A-Tile** sales. Perhaps your locality has no **Flex-A-Tile** agent. Write and ask for our proposition. Write today.

The Real Backbone of Lasting Strength is

No Furring Strips Are Required

This saves 5 to 10c a square yard. Sykes Expanded Cup Metal Lath, by its peculiar formation, makes a perfect key and insures a rigid, durable wall.

More Weight Gives Added Strength

Cut with wider strands Sykes Metal Lath is heavier than others of the same gauge. This adds to the solidity of the wall and to its durability.

For Interior Work and for Stucco Work Sykes Expanded Cup Metal Lath is the Best

Approved by Architects, Contractors and Builders. Indorsed by U. S. Government for Post Office Work. Write for Free Sample and Booklet of Specifications for Stucco and Metal Lath.

494 River Road, Warren, Ohio

Herringbone Residence, Oakland, Cal. Architect, C. W. McCall

Herringbone Rigid Metal Lath

Stucco exteriors, plastered interiors, ceilings—in fact, every metal lathed job will prove permanent when Herringbone Lath is used. Its rigidity insures ease and evenness of plastering, it grips the stucco or cement finish so firmly that cracks or falling are unknown.

Besides the economy of a job free from upkeep, Herringbone is self-furring, sheets are easily handled, interlocking edge prevents waste at side laps.

The Only Stucco That Can Be Applied in Freezing Weather

YOU need never "hold up" a stucco job on account of freezing weather if you use Kellastone Stucco. It can be applied in zero weather without being frosted or harmed in any way whatever. And it is the only stucco which will not loosen off, fall off or crack from contraction in cold weather or expansion in high temperature.

KELLASTONE

IMPERISHABLE STUCCO

Once applied, to stone, wood, tile, brick or metal, it holds with extraordinary tenacity. Normal settling of walls does not affect it. It defies moisture and fire. It is easier and less expensive to apply than any other stucco. It preserves its new appearance indefinitely—for years after other stuccos look old and dilapidated.

This is why Kellastone is used by the U. S. Gov't, by big factories everywhere, hospitals and private homes in city and country. Use it, too, for beautifying and renovating old houses and buildings.

Kellastone Composition Flooring

solves the problem due to the drawbacks of concrete, tile, wood, rubber-tile or other floor. It deadens sound, does not crack, has no wear wears indefinitely.

You ought to know all about Kellastone postal today.

Here's the Big, Quick Profit Chance You've Waited For!

OPPORTUNITY is pounding on your door with sledge-hammer blows through this advertisement. In response to our strong advertising in the leading magazines, thousands of people everywhere are demanding Edwards' Metal Ceilings, Tiles and Walls. Our business is growing so rapidly that we must have a good,

live agent in every community. *One representative* is wanted for each territory to demonstrate, take orders and apply Edwards' Metal Ceilings and Walls. Will *you* be the *one* man to reap the harvest of quick, easy profits? It's squarely up to you. But you must hurry. This opportunity won't linger.

Edwards' Metal Ceilings and Walls

Here is a chance to build up an independent, profitable business for yourself right at home. Many are now devoting their entire time to selling our metal ceilings and walls. Others have made big profits simply devoting part of their time to selling and applying our Metal Ceilings and Walls. No matter how you handle the proposition, the profit is in it, because the demand has already been created.

You Must Act Quick

Write us about your territory at once. This doesn't mean next month, or next week, or even tomorrow, but right now! One hour's delay may mean that someone else may be given your territory. Send the coupon. It brings our special agent's proposition and large illustrated Ceiling catalogue of attractive salesmaking designs.

BRANCH AT KANSAS CITY.

There Is Economy In Berger Building Material

Berger's Ferro-Lithic Reinforcing Plates

Are used extensively for reinforcing concrete slabs for flat or arched roofs and floors, sidings of buildings, sidewalks, etc. Plate is watertight in itself, which prevents dripping of soft cement and insures a dry roof even before concrete is applied.

Berger's Corner Beads

Insure a smooth, round corner to which the plaster properly adheres. Prevent plaster from cracking or chipping at the corners, thereby eliminating patching and doing away with old-fashioned wooden mould.

Berger's Base Screed

A metal screed that is nailed in place, affording a permanent ground for the plaster above and the cement base below. It protects both plaster and cement at all times, thus eliminates patching and insures a sanitary base.

Berger's Expanded Metal Lath

Adds strength and stability to a building. Used for Stucco Walls, Partitions, Ceilings and all kinds of work where plaster is required.

The diamond shaped openings are small and expanded in such a manner as to insure a perfect "Clinch" of plaster. It prevents cracking; does not swell, warp, or stain the plaster; prevents rats from making holes thru walls, and is quickly and easily applied.

Berger's Pressed Steel Cores, for displacing concrete and forming concrete joists in light long-span construction. *Berger's Rib-Truss Plates*, especially adapted for reinforcing thin concrete slabs for roofs, sidewalls, partitions and floors. *Berger's Multiplex Steel Plates*, for heavy service floor, roof, bridge and sidewalk construction.

Write for full particulars on products that interest you and ask for Catalog F. B.

FLEX-A-TILE

Roll Shingle

(PATENTED)

Some building owners say: "I like the looks of an asphalt shingle roof but I'm afraid I can't afford it."

Inexpensive as Flex-A-Tile Asphalt Shingles are, we have produced this Flex-A-Tile Roll Shingle to meet just such conditions.

A roof of Flex-A-Tile Roll Shingles *looks* the same as a roof of individual Flex-A-Tile Shingles. No paint or imitation process is used to give the individual shingle effect. No substitution of material is made. The Flex-A-Tile Roll Shingle contains the same identical material that goes into all our famous Flex-A-Tile Asphalt Shingles.

It gives all the advantages of an asphalt shingled roof with the extra economy and ease of application of a roll roofing.

Put up in 32-inch wide rolls—
108 square feet in each roll.
Packed with nails and cement.
In either red or green natural
stone surfacings.

71 Ruby St., Rockford, Ill.

Just what you've been looking for! —a combination Hollow Chisel Mortiser and Relisher

An entirely self-contained hollow chisel mortiser, that will carry chisels up to $\frac{3}{4}$ " square and make any larger or irregular mortise by overlapping the cuts.

Easy and simple to operate. No pounding or jarring. Every mortise perfect. No chips left to be picked out by hand, when you put your work on

the other side. Relishes out the tenon and bores away for that part which goes under the mold after you have completed the work on the sash stiles, rails and muntins.

Every carpenter and jobbing shop should have one of these machines.

Architecture Isn't Everything

WHEN a man enthuses over his new house or garage, it isn't usually the "beauty of line" to which he points with pride. It's the convenience and perfection of the equipment.

STANLEY Garage Hardware is the perfect finish for garage doors, designed to serve its purpose well: and it does.

The Stanley Garage Door Holder, illustrated above, adds little to the cost, but a whole lot to the convenience, of a garage. When a door equipped with the Holder is thrown open, it catches automatically and remains

securely locked in position, though "north winds may blow." Thus is prevented many a catastrophe to lamps, fenders and paint that might occur were the door free to slam against the incoming or outgoing car.

Such thoughtful provisions are bound to add to the business of the contractor or builder who is responsible for their installation.

In any case send us your name, that we may forward you from time to time information about new goods, etc.

The only makers of a complete and extensive line of Garage Hardware. Also makers of "Stanley Butts," etc.

Steel "Stitches" Every Few Inches

Columns which have staves simply glued together will surely open up. Columns which have any kind of a lock-joint are liable to open up. Columns which are glued under hydraulic pressure, where the staves are locked with a double V joint and sewed with cold rolled steel staples every few inches of their entire length *cannot* open up. And this is the way "Steel-Sewed" Columns are always made. Catalog explains the construction and shows many beautiful illustrations. Write for it.

AMERICAN COLUMN CO., Battle Creek, Mich.

CORTRIGHT Hand-Dipped Galvanized Metal Shingles

By the Cortright process each shingle is first stamped into shape from sheets of prime roofing tin, after which they are galvanized by dipping each slate or shingle separately into a bath of melted zinc, adding an extremely heavy coat. Contractors will find these shingles will appeal to their customers every time. The price is right—just like the shingles. Let us quote you.

"Acme" Brand SELECTED ¾" x 1½" Quartered White Oak FLOORING

Here is the greatest bargain ever offered in Quarter Sawed White Oak Flooring. Made of high-grade thoroughly kiln dried lumber, with modern machinery, by men who know how to make flooring that will save the carpenter many hours of hard labor in doing first-class work.

Mr. Milton Mathew, 814 Mulberry street, Marshall, Illinois, writes: "I laid some flooring last week from Chicago, and had to do twice as much work on it to get a finish as I did on the flooring I bought of you. I like that tongue and groove, it lays so easy and even."

Add one-third to the number of square feet to be covered and be convinced by sending a trial order. There is not one foot waste in a thousand feet, because it is all side and end matched. Shipments are made same day order is received, and you will find our flooring will save you many dollars.

YOUR OPPORTUNITY! HOUSE MOVING

You can clean up good money in the house-moving business. Let me show you how you can get started. You can have the benefit of my experience. I've cleaned up a lot of money in the past fifteen years moving houses. There's a bigger demand by the public today than years ago to move houses. People see that buildings can be moved with ease and quickly at a lower cost—with practically no damage to the building.

The property owner of today moves his house to a cheap lot—fixes it up and has an income. If he wrecked the building, he would have nothing but a few loads of dimension lumber.

Mr. Carpenter—Write me tonight. I'll show you how you can make \$1,500 to \$2,000 a year extra. Ask for my book E—it explains things.

E. W. La PLANT, Pres.,

La Plant-Cheate Mfg. Co., 625

Eastlack Ct., Cedar Rapids, Ia.

"the best mixer of mortars I have ever seen or used"—

So says Willard Myers, Bricklayer and Builder, 2000 E. Cambria St., Philadelphia

The LANSING ADVANCE MORTAR MIXER

is NOT a concrete mixer made over, but designed and built as a mortar mixing machine—one reason why it does its work well.

Saves TIME and LIME. The Lansing Advance with one or two men will do the work of six or eight men with hose—and do it much better. Economical for 5 or 6 masons or for 60.

With about $\frac{1}{2}$ less lime, the mortar is richer and stronger than can be mixed by hand. Every lot is absolutely uniform, smooth and easy to work. Each mason will lay 200 to 400 more brick a day, when you mix the mortar by the Lansing Advance.

Nearly all the largest buildings in recent years have been put up with mortar mixed by the Lansing Advance. This machine is built right. Simple, trouble-proof construction; ample power.

ASK ANY CONTRACTOR WHO OWNS A LANSING ADVANCE.

Rush Your Concrete Work

this Fall and get your contracts completed before cold weather sets in. Don't let Winter grip you in the middle of a job and tie up your work until Spring.

"THE STANDARD" Low Charging Mixer

will enable you to rush your work on account of the low platform, thus avoiding the necessity of high wheeling or the use of complicated side loaders. The charging platform is only 24" high and enables the materials to be dumped direct into mixing drum. The special arrangement of the drum insures thorough mix in minimum time and the light weight of the entire outfit allows the mixer to be moved along the job and the concrete distributed from the most advantageous position. The simple construction prevents breakdowns and delays.

"The Standard" is built in 10 sizes ranging in capacities from 3 to 40 cu. ft. of unmixed materials per batch and is carried in stock for immediate shipment.

Catalog No. 48-10 will be mailed on request.

NORTH CAROLINA PINE

Give Them Hardwood Effects Without the Hardwood Cost

The average home-owner today desires floors with a hardwood appearance, yet many cannot afford genuine hardwood.

Here is a particularly profitable field which you can successfully develop if you specify

North Carolina Pine

"The Wood Universal"

With this wood you can furnish a floor that will look as well, finish as well and wear practically as well as hardwood *at a much lower cost and greater profit to you.*

Judged from any viewpoint—strength, durability, beauty of grain or susceptibility to finish—it cannot be equaled at the price.

Your customer will be more than pleased with its results and you will gain a prestige of permanent value through its recommendation.

Our New Reference Book Is Yours for the Asking

Just write us today and we'll send you a most valuable Reference Book of North Carolina Pine. It shows the artistic effects possible for interiors and gives a description of its worth for every building purpose. Ask for Book B.

North Carolina Pine Association
Norfolk, Virginia

Residence of J. A. Currey, Portland, Ore., Roofed with J-M Transite Asbestos Shingles

To-morrow's Roofing and To-day's Opportunity

Opportunity is surely knocking at the door of every progressive builder. The signs of the times are plain—ordinances against inflammable roofing multiplying, and in all sections a steadily increasing popular demand for fire-safe construction.

JOHNS-MANVILLE TRANSITE Asbestos Shingles

meet this demand, affording a roof that is safe, sightly and in the highest degree durable. These shingles satisfy—they CAN'T burn, won't warp, rot or split, are easy to lay, free from repair expense, and are as cheap, if not cheaper, than any other fireproof roofing on the market. They represent a profitable investment for your customers—for you they are certain builders of bigger business.

You owe it to yourself to get the details. Why delay? A line to the nearest J-M Branch will put your name on the mailing list and show you the way to expand profits.

J-M Transite Asbestos Shingles are examined, approved, and labeled by the Underwriters' Laboratories, Inc., under the direction of the National Board of Fire Underwriters. Laid American method they are given Class "B" rating; laid French method they are given Class "C" rating.

WHITE ENAMEL Does Not Yellow on ARKANSAS SOFT PINE

This is a non-resinous wood of fine grain and lustrous texture, possessing well-balanced absorbing qualities which insure a finished enameled surface of sustained color, lustre and "life."

Because of the absence of pitch the white lead undercoating is applied directly to the wood without the necessity of preliminary shellacing. This method insures both a uniform absorption of the first coat and definitely avoids any tendency towards raised grain on the part of the wood itself.

Because of an abundant supply, Arkansas Soft Pine is readily obtainable and at a price notably less than that of rarer woods frequently recommended for this treatment. Upon its merits, therefore, together with the advantage of moderate cost, the wood is coming more and more into favor as an interior trim, not only for apartments and moderate priced houses, but for substantial homes as well.

White enameled and stained samples free on request. If you have not received your copy of our Architects' Manual, let us know. Address Dept. R.

Arkansas Soft Pine is Trade Marked and sold by dealers. See that yours supplies it. He can.

Please quote BUILDING AGE when writing to advertisers

Modern Construction of Small Town and Country Homes Requires the Installation of Carbide Lighting and Cooking Plants

Ask the good woman who cooks on a *carbide range* and lights her home with *carbide lights*—She will tell you that *Union Carbide* is doing more for country home folks and country home life than any discovery or invention of this age.

She will tell you that her Carbide-range has added to her health and happiness by shortening her kitchen hours and by making her cooking a much simpler and easier task.

She will tell you that the range is a practical duplicate of her city cousin's gas range and that she turns the fire off and on with a twist of her wrist—saving all the time and doing away with all the bother and dirt connected with handling fuel and ashes.

She will tell you that all these advantages are the biggest kind of a help towards keeping both herself and her kitchen clean and cool during hot weather months.

She will tell you that her carbide lights in every room and out on the porch are the cleanest, whitest and most beautiful lights in the world.

She will tell you, too, that all these lights are equipped with "friction igniters" to "light up" instantly with the pull of a little ornamental brass wire rod.

She will tell you that the handsome bronze and brass fixtures and the brilliancy of the light itself, has doubled the attractiveness and beauty of her home.

You must ask, too, the man of the house about Union Carbide itself—

He will tell you that in weight and bulk Union Carbide is quite like coal—that he gets his supply at factory prices, and that he gets it direct from the company's warehouse in his district.

He will tell you that his Union Carbide comes in blue and gray 22 inch—hundred pound "drums" (cans)—easy to handle, easy to store.

He will tell you that he keeps a six months' or a year's supply on hand in a corner of his barn or shed.

He will tell you that he himself not only comes in for his share of the benefits of the range in the kitchen and the lights in the home, but he has his own carbide lights throughout his barns and in the center of the yard round about—big brilliant ball lights operated the same as the house lights without matches.

He will tell you also that the double benefits of both lighting and cooking make Union Carbide by far the most economical and desirable lighting and cooking service for country homes.

And he will also tell you that the best proof that this is so is the fact that he is one of over 300,000 country home users to whom we now supply Union Carbide in the little blue and gray drums.

Building contractors can well afford to recommend the installation of a Carbide Lighting and Cooking Plant in every new small town or country home. Many contractors are now making a splendid profit acting as agents for Carbide Plant Manufacturers.

Send this coupon for our handsome advertising booklets giving complete information—with many illustrations.

Woods and Their Uses

ALL woods have certain uses for which they are especially adapted by reason of the peculiar qualities and characteristics which nature has given them; and on their proper selection for these uses, hinges the whole problem of economy in wood construction.

Three centuries of experience in this country have demonstrated that no other wood lasts so long or gives such satisfactory service as

WHITE PINE

for outside finish lumber—siding and corner boards; window sash, frames and casings; outside doors, door frames and casings; outside blinds; all exposed porch and balcony lumber; cornice boards, brackets, ornaments and mouldings; and other outside requirements, *not* including shingles.

If the lumber dealers supplying your clients are at any time unable to furnish it, we should appreciate the opportunity of being helpful to you in securing it.

A Free Magazine for Contractors

We are now publishing a bi-monthly architectural magazine, every issue of which is full of valuable and helpful information for contractors and builders. If you would like this magazine, write us and we will be pleased to place your name on our mailing list.

THE H. B. IVES CO.

SOLE MANUFACTURERS NEW HAVEN, CONN.

Samson Spot Sash Cord

Made of extra quality stock, carefully inspected and guaranteed free from the imperfections of braid and finish which destroy common cords so quickly.

The Spots on the Cord, in any color, are our trade mark, used only with this extra quality.

Samples and full information gladly sent.

Samson Cordage Works
Boston, Mass.

MORE MONEY FOR YOU!

MR. CONTRACTOR, build up a profitable business this Winter laying and finishing our Fine Hardwood Flooring.

You will find many houses in your town which need new floors, and the time to put them in is when the cold weather prevents outside work.

No special experience is required. Our books give you full information about the flooring and how to lay it. Our Service Department helps you get the orders.

Why not learn more about this money-making sideline now? Write today for our Special Agency Plan.

THE INTERIOR HARDWOOD CO.

1329 BEECHER STREET

INDIANAPOLIS : INDIANA

"Stucco Coated frame residence" from July Building Age. Geo. J. Hardway, architect.

"The shingles of the roof were dipped 10" in Cabot's Shingle Stain before being laid, and they were given a brush coat when the house was finished. The stucco finish received two coats of Cabot's Stucco Stain."

Cabot's Shingle Stains

They have been the standard for more than twenty-five years, and are specified by nine-tenths of the architects, who know them from experience. Their colors are soft, rich and beautiful, and guaranteed fast. Their vehicle is Creosote, which thoroughly preserves the wood, and they contain no kerosene or other cheapener. Why experiment with unknown stains, when you are sure of Cabot's?

Cabot's Stucco Stains

are the only artistic cement finishes. They give soft, natural coloring effects, without covering the surface with a painty coating. They are also cheaper than coatings and easier to apply, and they cannot crack or peel.

You can get Cabot's goods all over the country. Send for samples and name of nearest agent.

Lathing

Siding

Section of Outside Wall of House, Showing Wool Between Studding.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

U. S. Mineral Wool Co.

280 Madison Ave., New York
(Cor. 40th St.)

NEW YORK, OCTOBER, 1916

A HOUSE IN A CLEVELAND SUBURB

INTERESTING EXAMPLE OF THE DUTCH COLONIAL
TYPE—THE LIVING ROOM A FEATURE—COST \$4,000

THE Colonial type of residence has attained wide popularity in all sections of the country by reason of the sincerity and honesty of purpose which its architecture seems to express. Among the several styles evolved from the same prototype, the Dutch Colonial holds its own, for the characteristic gambrel roof which immediately identifies it to the popular mind admits of an economy of plan and grace of outline that appeals powerfully to many. These considerations have caused us to select for illustration and description a Dutch Colonial house which embodies many interesting features.

The footings are of concrete composed of one part of Portland cement and four parts crushed stone. The foundation walls and piers, except the outside facing, are of hard burned hollow tile and brick. A concrete basement floor 3 in. thick-

ness is laid on top of a 3-in. broken stone foundation. The lower 2 in. of the floor consists of one part of Portland cement, two parts sand and four parts of crushed stone and the 1-in. finishing coat contains equal parts of cement and sand.

The joists and studs are of yellow pine placed 16 in. on centers. The first floor joists are 2x10 in. and the second floor and attic joists 2x8 in. The ceiling joists, and rafters are 2x4 in., the ridge poles 1x6 in., and the collar beams, plates and studs 2x4 in. The studs are double and braced at all corners. The double floor joists run lengthways under the partition and block joists run crossways. The floor joists where not in one piece are spiked together over the bearing, forming one continuous tie. All joist spans of 12 ft. or over have 2x3 in. bridging. The collar braces are nailed to the rafters half way between the ceiling joists

PLANS, ELEVATION AND MISCELLANEOUS CONSTRUCTIVE DETAILS

and ridge line. The rough underflooring for the first and second floors is $\frac{7}{8}$ x6 in. matched yellow pine laid at right angles to the joists with all butt joints over the joists. The finish floors are of $\frac{7}{8}$ x2 $\frac{1}{2}$ in. select plain sawn oak except the attic floor which is yellow pine.

The exterior studs are covered by $\frac{7}{8}$ x8 in. ship-lap sheathing boards, water-proof building paper and siding. The sides of the porch, including the porch rail and dormers, are covered with 10-in. cypress siding laid 9 in. to the weather. The exterior trim is for the most part 1 $\frac{1}{8}$ in. cypress. The ceiling of the porches and soffit of the over-

as to render the work thoroughly waterproof.

The exterior color combination involves white for the body of the house with the blinds and shingles green.

The exterior wood work in addition to the priming coat was painted with two coats of National Lead Company's "Dutch Boy" pure linseed oil and white lead, and the porch ceilings were given two coats of Berry Brothers' oil stain. The shingles were given one coat of Berry Brothers' shingle stain after they were laid, and the exterior varnished doors have a final coat of Spar varnish.

The house faces the east and has a wide porch

VIEW IN LIVING ROOM LOOKING ACROSS THE STAIR HALL INTO THE DINING ROOM

hang is $\frac{7}{8}$ x2 $\frac{1}{4}$ in. yellow pine. The porches and rear steps are built of 1 $\frac{1}{8}$ x2 $\frac{1}{4}$ -in. cypress.

The rafters are covered with $\frac{7}{8}$ x4 in. square-edged yellow pine roof boards surfaced on one side and spaced 2 in. apart, on which are laid red cedar shingles exposed 4 $\frac{1}{2}$ in. to the weather. The shingles were dipped in Berry Brothers shingle stain before being laid. Scott's extra coated I. C. tin was used for all tin work except for the valley and gutters, which are of I. X. tin. The galvanized iron gutters are 5x3 in. moulded. The down spouts are connected to the sewer.

The sleeping porch is covered with 11-oz. canvas laid on white lead and oil, well tacked in place, the necessary flashing being provided so

extending the length of the south side and partly covered with lattice. A lattice is also built around the front door, as shown in the halftone picture of the exterior. The building is approximately 28 ft. 6 in. wide and 24 ft. deep. In the rear is a sleeping porch so located above the back porch and refrigerator room that it does not detract from the artistic appearance of the house. This porch, instead of being on a level with the second floor, is at a slightly lower level opening from the stair landing.

On entering the house the living room appears at the left, this measuring 12 ft. wide and 23 ft. long, or the full depth of the house. In the center on one side is a cozy red brick fireplace and mantel

and on this side, near the front, is the door with twelve panes of glass, which leads on to the porch. The fireplace has a 6x3-in. red unglazed tile hearth resting on a 3-in. bed of cement grout the entire width of the mantel. Under the wide front windows are window seat and drawers, and the wall space on this side not taken up by the windows is filled with bookcases on one side and a coat closet on the opposite side. The latter adjoins the front hall into which it opens, having a false door in the living room corresponding to the bookcase door.

The dining room at the right of the hall is approximately 12 ft. wide and 12 ft. 8 in. deep. The stairway at the back of the center hall is unusually wide. The kitchen adjacent to and back of the dining room is conveniently arranged, com-

coting extending to about 18 in. from the ceiling.

All the first floor doors are 1¾ in. in thickness. The front entrance door is of Dutch design veneered in quarter sawn oak and with separate upper and lower sections with thin American plate glass panels set in the upper section with wood stops in muntins 3-16 in. between the glass. A "Korelock" door veneered in oak and having glass panels affords communication between the living room and porch and a similar door leads from the stair landing to the sleeping porch. The remainder of the doors are of Korelock type, those on the first floor matching the rooms they face and those on the second floor 1⅝ in. in thickness being veneered in birch. All the windows have 1⅝ in. rolled slat blinds with a solid upper panel. The blinds on the front of the house do not close.

VIEW IN LIVING ROOM OF HOUSE IN A CLEVELAND SUBURB,
LOOKING TOWARD THE FRONT

modious and well lighted, and has a built-in cupboard on each side of the sink on one side and a third cupboard on the opposite side with galvanized clothes chute leading to the basement. A narrow stairway leads from the kitchen to join the main stairway at the landing. One door leads from the kitchen to the cellar and back entrance and another to the refrigerator room and a back porch 5 ft. 6 in. wide with steps the width of the porch.

The walls are covered with one coat of Tiger brand hydrated lime plaster with a finishing coat of Tiger brand White Rock finish. The bath room and kitchen are wainscoted 4½ ft. high with Best Brothers cream cement ruled into 6x3-in. blocks to represent tile.

The hall, living room and dining room are finished in plain sawn oak and the second floor in birch. The remainder of the trim is slash grain Georgia pine. The dining room has wood wains-

The oak floors were given one coat of Berry Brothers' paste filler, followed with two coats of Berry Brothers' floor wax rubbed with a weighted brush. The birch doors received one coat of shellac and two coats of Luxeberry wood finish, the last coat flat. The doors were sandpapered between coats. The oak trim and doors on the lower floor received one coat of stain, one coat of paste filler and two coats of wax, all of Berry Brothers make. The entire trim on the second floor is white, the bed rooms and bath room being given three coats of white enameled primer, followed by two coats of Luxeberry white enamel.

The main stair treads to the second floor are 1⅝ in. oak with ⅞-in. oak risers. The rear stairs are of yellow pine and have 1⅝-in. treads and risers. The closets are finished the same as the rooms in which they open and are provided with ⅞x12-in. shelves.

The arrangement of the second floor includes two bed rooms across the front of the house, another at the rear and a large bath room at the right, all connecting with a central hall wherein is provided a large linen closet conveniently placed both as regards bath and bed rooms. All the bed rooms have fair-sized closets and the closet door in one of the front rooms is fitted with a full-length mirror. The sleeping porch is also reached from this hall.

The bath room is equipped with modern fixtures, among which is a medicine cabinet with a

pensive water closet. The kitchen sink has a Kohler 22x30-in. porcelain-enameled sink. The building is piped for gas and wired for electricity.

The house here described is located at 1400 Noble Road, Cleveland Heights, a suburb of Cleveland, Ohio, and is occupied by the owner, W. G. Grayell. The plans and specifications were prepared by the John Henry Newson Company, architects, 1027 Williamson Building, Cleveland, Ohio, and they state that under ordinary conditions the house can be erected in that section of the country at a cost ranging from \$4,000 to \$4,500.

20x24-in. plate-glass mirror in the door, a 5½-ft. Kohler "Baroness" porcelain enameled tub, a Speakman shower and Trenton Pottery Company "Raleigh" Vitras china lavatory and Liwelco closets and Bellemeade tank. The bath room has a floor of 1-in. white hexagon tile laid on 3 in. of cement grout.

The house is heated with a D. E. Henry Company 26-in. Moncrief combination gas and coal furnace with Perfection wall pipe with black japanned registers. To the furnace is connected a 40-gal. Hoffman water heater.

In the basement there is also a two-part stone laundry tub, a two-burner hot plate and an inex-

The builder executing the work was Fred S. Wallace, 13701 Kinsman Road, Cleveland, Ohio.

"Colorado architects some time ago conceived the idea that they could do much to improve architecture in the rural district. We believe," says Secretary Manning of the Colorado Chapter of the American Institute of Architects, "that we can accomplish this purpose by devising a series of plans of various types of farm buildings and country homes, which can be placed at the farmers' disposal at a minimum of expense. In this manner he will be able to build not only more substantial structures but more beautiful and comfortable ones."

HOW COST OF BUILDING MAY BE REDUCED

AN ECONOMY IN CONSTRUCTION WHICH COMES FROM THE USE OF BETTER PLANS AND SPECIFICATIONS

BY ALBERT M. WOLF

COMPARATIVELY few house-builders realize that extra money spent on more complete and detailed plans, than are in general used for residence construction, results in better buildings, tends to eliminate high and unbalanced bids, as well as the vexing and costly "extras" which are the bane of a house-builder. The prevailing idea seems to be that if too much detail is shown on the plans, the contractor will include items in

his estimate which he would otherwise omit. This may be true in a few isolated cases, but in general such a policy acts more or less as a boomerang, for before the building is finished, the contractor has accumulated such a bill of "extras" as to make the final cost much more than it should be. In fact, this has become so typical of residence construction that when one speaks of building, the first question asked is, "Have you allowed enough for the 'extras' which are sure to develop?"

WHY POOR PLANS ARE OFTEN USED

It is indeed regrettable that such a state of affairs should exist, but it does, and the blame rests with the owners and architects, sometimes with one or the other, and sometimes with both. Most persons when desiring to build a house want to secure plans at just as low a price as possible, since they figure that plans are no tangible asset as far as the completed house is concerned. To meet this demand, there have sprung up in various parts of the country architectural drafting firms and plan bureaus catering to this class of trade.

The plans and specifications furnished by these firms are often not much more than what an architect would call study plans and outline specifications, for details are for the most part left entirely to the imagination of the contractor, and if he be unscrupulous the owner suffers during the building process, both in quality of work and through the numerous extras.

WHY SO MANY CHANGES ARE MADE

Then, again, people decide to build and want to start work at once; they consult an architect or builder before they have fully made up their minds as to the general layout, and as the construction proceeds they see things which do not meet their fancy, and changes must be made. This condition is probably due in a measure also to the inability

of most people to visualize, or, as we say, to picture in their mind's eye just how the interior of a residence will appear, with the plans as the only basis for the imagination. This is also the reason why so many people select some house previously built, if it strikes their particular fancy, and have one built along the same lines, possibly without anything more than a floor plan and a few sheets of specifications as a guide. As the construction proceeds a thousand and one little points come up as to which way the work shall be done, but not having a rigid specification the owner must take whatever the contractor desires to furnish, or pay for an "extra" if the work is carried out in the manner he (the owner) desires.

DETAILS OF HOUSE CONSTRUCTION

Residence construction includes so many different trades and so many classes of work that just as much detail and sometimes more is required in the plans and specifications as in those for office and manufacturing buildings. If such work is taken by the architect on a percentage basis (that is, his fee is to be a certain percentage, say 5 per cent, of the cost for ordinary residence work) he cannot make very much profit, since the cost of getting out plans and of the supervision is relatively high as compared with larger work. This has led many architects to ignore residence work entirely or to turn out "sketch plans" and outline specifications which are more in keeping with the fee to be received.

NO GAIN IN USING INCOMPLETE PLANS

Assuming for a moment that lower bids are occasionally obtained by the use of incomplete and poorly detailed plans, it cannot be denied that if the contractor has to furnish more under such a contract than he originally intended he will be rather inclined to add enough to cover all "contingencies" the next time.

Should those owners and architects who are believers in the use of sketch plans for bidding purposes, try the other method—that of getting more complete plans which would leave no doubt in the contractors' minds as to what is desired—they would soon find that the contract price in such cases represents very nearly the final cost instead of only a portion of the ultimate cost. This is the result of eliminating the source for "profitable extras" to the contractor by specifying definitely and showing in detail just what is required and not trying to cover things not specified or clearly shown, by "blanket clauses" such as "The contractor shall furnish all material and labor necessary to fully

execute the work in accordance with the intent of the plans and specifications."

The architect should know exactly what is required and it is his duty to clearly show or specify everything necessary to completely construct the building. Now by this is not meant the writing of a voluminous specification covering points which should be clearly shown on the plans. The specifications should cover general conditions of contract, quality of materials, methods of executing certain classes of special work and such other construction features as cannot be readily shown on plans without the use of long and wordy "notes."

POINTS SPECIFICATIONS SHOULD COVER

For the General Conditions of contract, forming part of the specifications, the Standard Forms of the American Institute of Architects, or the Illinois Building Contract Documents, are recommended as being very carefully drawn up and so complete as to cover all points likely to arise in the interpretation of specifications and execution of contract. Most specifications omit such important features as precedence of drawings, condemnation and correction of defective work, changes in work, additions and deductions, arbitration of differences, right to terminate contract, and supervision. The Forms mentioned above cover these very explicitly, in addition to many others, and herein lies their value as a safeguard to the interests of the owner.

These Forms can be obtained in printed form in several different sized sheets so as to be readily incorporated with the usual typewritten detail specifications. Their adoption by architects of recognized high standing is a demonstration of their worth and the writer would recommend them for use in residence contracts and specifications in order to avoid difficulties encountered if the contractor is inclined to disregard the specifications.

The general plans sent to bidders need not show all large and full scale details which will be necessary to carry out the work, but sufficient detail should be shown to allow the contractor to accurately take off the quantities of materials without any stretch of imagination on his part as to what the architect had in mind when he drew up the plans.

SCOPE AND GENERAL MAKE-UP OF PLANS

For an ordinary residence the bidding plans should comprise:

1.—Plat plan, showing location of house on the lot, the general ground elevation at various points, and the relative elevation of basement floors, kind of soil to be encountered, and enough data so that the amount of excavation can be readily computed.

2.—Basement and foundation plan, showing sizes of all wall footings, piers, location of all heating and plumbing fixtures and the underground piping.

3.—Floor plans, giving all necessary dimensions to accurately locate all partitions and openings, sizes of all doors, kind of plaster finish and trim in the various rooms, location of all plumbing and lighting fixtures, all radiators or heating flues, all built-in fixtures such as bookcases, window seats,

buffets, wardrobes, linen closets, clothes chutes, ice-box, cupboards, and shelving.

4.—Roof plans, showing type of roofing, valleys to be flashed, detail of covering for hips and ridges, balloon strainers in downspouts, skylights, etc. It may also show any special work in attic.

5.—Elevations of all sides of the building, showing the sizes and type of all windows and interior doors, exterior finish, downspout locations and details, slope and general lines of roof, and heights of various stories.

6.—Detail sheets, showing sections of the building disclosing typical or special features of construction; window frame, lintel, and sash details, details of floor and wall construction (if of concrete as is now becoming popular). On one of the detail sheets (if more than one is required), should be shown the details, to a fairly large scale, of the millwork, including various parts of trim and all cabinet work.

PLANS SHOULD SHOW AS MUCH AS POSSIBLE

It should be borne in mind when drawing up plans, that contractors, especially sub-contractors, are very lax in reading and following the specifications, and that for this reason as much should be shown on plans as can consistently be done. For example, the sheet metal contractor is very likely to disregard the specifications and refer to the plans entirely while taking off his quantities, and as a result if nothing is shown to guide him, he will estimate and bid on whatever quality of material he desires to furnish. To avoid mistakes then, the size, weight and detail of all conductor pipes gutters, cornices, ridge rolls, valley flashing, etc., should be indicated on plans and not described in the specifications. For the same reason the various kinds and thickness of glass, special notes on millwork, notes on tilework, notes on methods of laying up special brickwork, terra cotta, etc., should be plainly shown on the plans, instead of trusting to luck that the specifications will be followed in the way that they should.

If carried out as enumerated above the sheets of plans for a residence will be more numerous than is usually the case, and consequently will cost more. This extra expenditure, however, is justified in view of the fact that on a seven-room bungalow, 55 ft. x 30 ft. (exclusive of wings), built by the writer and fitted with all the most modern conveniences, not one cent was paid out for extras.

In this case the writer had trouble getting bids from contractors who were at any time ready and willing to take jobs based on mere sketch plans. Either they did not know how to estimate a job when all details were given, or else they saw no chance of substitution or "extras" and consequently did not care for the job. No trouble was experienced in getting honest contractors to bid, for they could at once see that they were bidding on a definite proposition, and not one which depended entirely on the state of mind of the owner or architect.

The writer further believes that if more study and care was exercised in the making of plans, better buildings would result and cost data at our disposal would be of more value.

SOME ASPECTS OF MODERN SHINGLING*

SOME INTERESTING INFORMATION RELATIVE TO THE METHODS OF SHINGLING VALLEYS—THE MANNER OF FLASHING

BY EDWARD H. CRUSSELL

THERE are two general methods of shingling valleys—open and close. In the open valley a space is left, from 2 to 6 in. wide, forming a sort of gutter from the eaves to the top of the valley. In the close valley the shingles come close together in the center. Both styles need flashing to make them weatherproof, and for this purpose sheet

tin or galvanized iron is generally used.

For the open valley, the flashing is locked, or riveted, and soldered together so as to make a continuous strip the full length of the valley. This is laid on the roof boards, and after being pressed

with the courses of shingles as they are laid. These pieces of tin are known as tin shingles; they should be folded so that the 10-inch way extends along the valley and placed so that their lower edges just come even with the lower edges of the courses of shingles *under* which they are laid. A tin shingle should be placed under every course.

Some workmen place the tin shingle so that it comes even with the lower edge of the course over which it is laid, thus exposing from 4 to 5 inches of the tin shingle. Nothing is gained by this method and the appearance of the finished work is very often marred by it, yet this is the method advocated in one of the best works on building construction published. On roofs of unequal pitch, the width of the courses must be varied on one side or the other so as to make them meet in the valley, otherwise course flashing cannot be used.

Fig. 41—Valley Shingling, Showing How Tops of Shingles Are Kept Even

Fig. 42—Showing Another Method of Valley Shingling

into place is fastened with a few nails driven through its outer edge.

The close valley can be flashed in the same manner, or what is called course flashing may be used instead of it. The latter consists of sheets of tin, about 10 x 14 inches in size, which are worked in

*Copyrighted, 1916, by Edward H. Crussell.

There is no difficulty in applying the strip flashing; the only thing to be remembered is to place the flashing the right way of the lap; that is, so that if the solder in the joints should let go, the water will run over the joint instead of into it. The flashing should be from 16 to 20 inches wide, the low roof pitch taking the wide flashing.

In shingling the valley, care should be taken to see that the nails are only driven through the outer edge of the flashing, and the most important thing for the novice to remember is, that the tops of the shingles must be kept even, not the butts.

Many a beginner has been tripped up by this simple little matter, and many are the stories the old-timers tell of some greenhorn keeping the butts even, until the shingles in the valley were from 6 to 20 inches thick.

In Fig. 41 is shown the shingling of a valley and how, by keeping the tops even, the shingles are run out to a feather edge. These small pieces of shingle are difficult to cut, hard to nail (through the flashing), and entail a lot of waste unless there is a hip on the same roof; in which case, the pieces cut from the valley shingles may be used on the hip and *vice versa*.

A different method of cutting the valley shingles

that is exposed of the beveled shingles in the finished roof. A short, straight edge is needed for lining the courses at the valley; it is used by laying it against the butts of the shingles already laid. The shingle A is brought to the center line of the valley for a close valley, and to the side line for an open valley.

The usual method of laying an open valley is to snap two chalk lines up the valley, allowing for the necessary width of opening. It is an exceedingly difficult thing to shingle to a line in this place, partly because the upper edge of the shingles (or the edge which shows) is an inch or so above the line, but more because the lines are sure to be rubbed out before the valley is half finished. Open valleys with crooked edges seem to be the rule rather than the exception and it is no unusual thing to find them wider in the center than they are at either end.

The easiest method of lining an open valley is to lay a stick of timber, such as a 2 x 4, up the

FIG. 43—ROOF DORMER WITH SHINGLED WALLS

is shown in Fig. 42. This method is condemned by some, chiefly because the grain of the shingle runs up and down the valley instead of up and down the roof. Those who condemn the method evidently overlook the fact that only a very small portion of this shingle is exposed, and, considering the ease of fitting it, as compared with Fig. 41, the present writer's opinion is that it is very much the better method of the two.

The manner of working Fig. 42 is shown quite clearly in the illustration. A straight shingle A is first laid with its lower inner corner to the line of the valley; a *wide* shingle is then trimmed with the hatchet to fit against it, as shown at B, and that is all there is to it. The next course is laid in the same way—first the straight shingle and then the beveled, and so on to the finish. The shaded portions on the lower courses of Fig. 42, show all

center of the valley, bracing it in position with a few pieces of shingle. Even where a tapered valley is required (one wider at the bottom than at the top) it is better to cut a pattern to the proper taper than to try and shingle to a line. A trial of both methods will convince the most skeptical.

An item of shingling likely to prove a stumbling-block to the inexperienced is to be found on the dormer window shown in the picture Fig. 43. There is no horizontal line anywhere on the side of this dormer and a level is needed for lining the courses. The tops of the courses must be kept even, as shown in Fig. 44, although the tendency to run them up is even stronger here than at the valley.

Some little calculation and forethought are needed in working on a roof of this kind. The main roof must, of course, be shingled first, and the upper portion of it, under the dormer overhang, and also

the side walls of the dormer, should be shingled before the dormer is roofed in. Then the main roof must wait until the dormer is shingled, so that the upper end of it may all be finished at the same time.

The manner of flashing between the main roof

Fig. 44—Shingling on Side of Roof Dormer

and the sides of the dormer is shown in the upper portion of Fig. 44. A tin shingle 7 x 7 inches in size* is bent at right angles and worked into each course of the shingles on the main roof as they are laid, in the same manner as explained for the valley, or so that the lower edge of the tin shingle comes even with the lower edge of the shingle that is laid over it. This method of flashing should be used wherever a shingled roof butts against a perpendicular wall, as for instance the roof of a one-story extension against the wall of the main building. If the wall of the main building is covered with siding or clapboards, the flashing should be placed so as to go behind it, but sometimes, especially on repair work or alterations, the arrangement pictured in Fig. 45 is employed. The flashing is placed on the outside of the siding and is closely nailed to it, after which a member, which we may perhaps term a base, of the same thickness as the corner boards, and with a beveled upper edge, is nailed in place over it. The upper edge of this member should also be covered with a narrow strip of flashing. Tin shingles, used as in Fig. 44, is a

Fig. 45—Showing Method of Flashing Sometimes Used

better method of flashing than the long, single strip of tin often used for this purpose.

A method of flashing a chimney is pictured in Fig. 46. In the drawing, the sheet of tin for the front of the chimney is shown covering a number of short shingles in the course A. What may be considered

*A sheet of tin is 20 x 28 inches and the tin shingle, though called 7 x 7, is usually 6½ x 7 inches, so as to cut the sheet without waste.

a better method is to omit these short shingles entirely and let the flashing rest on the course below. The end shingles in the course A will then stop at the sides of the chimney and the ends of the front flashing will be covered and held down by them.

The side flashing is worked into each course in the same manner as described for the dormer, the upper end of the flashing being embedded in the joints of the brickwork for about 1 inch. The mortar is raked from the joints to permit of this being done, and the flashing, after being turned into place, is held with a nail or a small plug of wood. After the flashing is all finished the joints are again filled with mortar. The piece of flashing for the back of the chimney should be long enough to extend up the roof under four courses of shingles.

Sheet lead will make a much neater and better flashing than tin, but on account of the extra cost is seldom used. A compromise between the two methods is to use sheet lead for the corners only.

Circular towers with conical roofs are not used as much on the modern residence as they were for-

Fig. 46—Flashing and Shingling Around a Chimney

merly, but there is no telling how soon they may be again in favor and there is a little item in connection with them it may be well to mention. The roofs of these towers were after decorated with several rows of ornamental dimension shingles. In nearly every case the fellow who figured the job overlooked the fact that on a conical roof each course of shingles is smaller than the one below it, and that if ornamental shingles are used, each separate shingle will need trimming to size.

Another thing that puzzled some of the shinglers was how to strike a line for the courses of shingles. The answer, of course, is, fasten one end of a string to the apex of the roof and tie a pencil to the other end. This will strike a horizontal line around the roof surface, the height of which can be varied by shortening or lengthening the string.

(To be continued)

A MODERN HOUSE OF HOPI ARCHITECTURE

When the first Spaniards explored what is now California and the surrounding States, they found a style of architecture among the Indians which has seldom been equaled for adaptability to en-

vironment. The sole idea of the builders was to erect dwellings which should so blend in with the surroundings that, even to the keen eye of a hostile Indian, they would be barely distinguishable from the encircling buttes.

Modern ingenuity has taken this old style of architecture and selected a type which, although common to many tribes of Indians, yet presents features saliently Hopi, and patterned after it a dwelling in La Jolla, a small town about ten miles from the city of San Diego, Cal.

The house is built against a bluff which towers, tier on tier, back into the distance, while in the front, the sparkling blue of the Pacific Ocean lends a beautiful tone to the view.

Keeping this environment in mind, a house was designed to be built of stucco in the shades of tan which would match the sands of the bluffs. An original note, not found in the prototype, was introduced in the deep shade of blue which seems to have been stolen bodily from the palate of the ocean to tint the doors and window casings. This same color scheme of tan and blue is carried out in the interior decoration so that nowhere might the hand of man sound a discord in the suggested color scheme of Nature.

Huge beams, hand hewn from telegraph poles, form the floor levels and project beyond the walls.

The house is approached by means of a narrow irregular flight of stairs which takes full advantage of the inequalities of the ground so that they might appear impromptu and inconspicuous. Entrance is had high up, almost to the roof, leading into a small hall containing a dressing room on one side and a staircase leading down to two bedrooms, a bathroom and a sleeping porch, which constitute the first floor plan. There is also a separate first floor entrance. The upper hall also leads, by way of two steps down, to a large living room done in plaster and with a front composed entirely of glass windows opening upon a balcony or terrace. Back of the living room is a small kitchen with a tiny bedroom adjoining it. Interior decorations are of Hopi design and various knickknacks of the same tribe lend their picturesque aid to give local color.

The flat roof, so characteristic of this type of architecture, is reached by means of a Hopi Indian ladder, which has one side much longer than the other. A more convenient and equally picturesque ascent can be made by means of a flight of broad steps that go up outside of the house on the opposite side to the regular entrance. A square chimney, huge enough to throw a protecting shade, affords shelter from a too warm sun. The house is intended to perpetuate some of the traditions and architecture of the Hopi Indians who inhabited the deserts of Arizona.

Atlanta, Ga., recently passed an ordinance prohibiting the use of wooden shingle roofs in that city after the first of January, 1917. The repair of more than 50 per cent of a roof area with wooden shingles is also prohibited after that date.

CHANGE OF "BUILDING AGE" ADDRESS

We desire to announce to our readers and patrons that with this issue, *THE BUILDING AGE*, founded under the name of *Carpentry and Building* by David Williams in January, 1879, passes to the control of the American Architect, Inc., with offices at 50 Union Square (Fourth Avenue and Seventeenth Street), New York City. Plans looking to this change have been under consideration for some time past and were completed on Sept. 1. *THE BUILDING AGE*, however, will continue as a separate publication devoted to the same field as heretofore. There will be no material change in the editorial policy which for thirty-eight years has maintained *THE BUILDING AGE* upon a high standard of excellence for those practically engaged in moderate cost construction work, but various modifications will be made in the typographical features, some of which will be noticed in the current number of the paper.

SUGGESTIONS FOR INTERIOR AND EXTERIOR TREATMENT

We continue this month the presentation of the series of excellent pictures which afford suggestions for the treatment of entrance doorways and interiors of modern houses of a type calculated to interest the practical builder as well as the young architect. These pictures represent a variety of treatment, the first one showing a quaint design of entrance with the French doors framed in a trellis work for climbing vines and with seats on either side.

There are two interiors of stair halls each of which may also be used as a reception room, and there are also two dining room interiors which sharply contrast in their wall treatment.

The fourth page presents an excellent assortment of designs of modern entrance door hardware, all of which cannot fail to prove of special interest and value to the progressive builder who is ever on the alert for suggestions which he can utilize in a practical way in his business.

THE INVESTING BUILDERS' ASSOCIATION

One of the results of the new Zoning and Height Limiting Restrictions Law with which the builders of New York City, and more especially those concerned with the erection of high-grade apartment houses had much to do, is the organization of what is known as the Investing Builders' Association, with officers for the ensuing year as follows:

President.....J. E. R. Carpenter
1st Vice-President.....Alex. M. Bing
2nd Vice-President.....Edgar A. Levy
Secretary.....David Tischman

The purpose of the organization, among other things, is to treat as a unit with sub-contractors and to look after labor-law matters and such legislation as may prove oppressive and unwarranted.

EFFICIENCY IN MODERN HOUSE PAINTING

SURFACES TO BE PAINTED MUST BE CAREFULLY CONSIDERED—TWO GENERAL CLASSES—OLD SURFACES

AT some time or another most of us have kidded carpenter friends about being "wood-butchers," but now along comes a man who calls himself a "Paint Doctor." Odd, isn't it?

But there is at least an interesting likeness between the physician and the painter. The former must study his patient, learn what is wrong, prescribe and treat him. And the painter, to succeed in all of his work, must consider carefully the surface he is to paint and analyze the conditions under which he is to work.

THINGS TO DO BEFORE PAINTING A BUILDING

When called upon to paint a building this Paint Doctor thinks it is an advantage to examine it and find out the kind of lumber or paint used, says a writer in the *Carter Times*. If the old paint went wrong, he tries to find the cause, so as to guard against its occurring again. When the paint has scaled, he wants to know why. Was the fault in the paint or the wood? With a case of blistering, was wet lumber responsible, a leaky gutter, a careless painter or moisture from other sources? Was the wood primed with yellow ochre, which absorbs moisture and doesn't dry, or else throws off the finishing coats?

To get the most value out of a paint investment involves quite a comprehensive knowledge of materials, conditions and men. It means finding out the one best way to paint each house, and that amounts to the much talked of "efficiency" of to-day. No two surfaces are exactly alike, but on new work they may be conveniently divided into two general classes: In the first are dry, porous soft woods, such as white pine, poplar, white wood, cotton wood, etc. The second class consists of such lumber as presents a hard surface well filled with sap, which makes it difficult for paint to anchor itself in the pores sufficiently to avoid scaling, such as pitch pine, cypress, redwood and red cedar.

THE WHITE PINE CLASS OF SURFACES

With the white pine class of surfaces it is desirable to get as much oil as possible into the wood and paint. The amount and the quality of the linseed oil used determine the length of satisfactory service rendered by the paint. On new lumber at least three fairly thin coats ought to be applied. To use but two requires that the paint be mixed thick to cover well, and thick paint does not carry sufficient oil to satisfy the lumber and bind the pigment to the surface as well. Too few coats, which means too little oil, on this kind of surface result in premature and rapid wearing off of the paint. In the case of gray or slate colors produced with lamp black spotting, or fading in spots, also results. Thin coats are better than thick because they carry

more oil, dry better and brush out more uniformly.

The pitch pine class of lumber is used to-day on most new buildings. It is not more difficult to handle, but requires different treatment. The priming coat should contain less oil and more turpentine. Probably two-thirds oil and one-third turpentine will be found best on an average and will give a surface that does not possess too high a gloss to take the second coat well. It should dry with a semi-flat or eggshell gloss surface.

THE PITCH PINE CLASS OF SURFACES

For the pitch pine class of lumber tests made under the direction of the New Jersey Master Painters' Association showed excellent results from the use of a priming coat mixed in the proportion of 34 lb. of Carter pure white lead, 66 lb. Carter dry red lead, 6 gal. raw linseed oil, 1 gal. turpentine and 1 qt. of japan drier. Finishing coats are of pure white lead mixed in the usual way. This requires a three-coat job, but it is cheap insurance against scaling paint, and three coats will usually wear enough longer than two to offset the little additional expense. When white lead is used with a primer on the pitch pine class of lumber the addition of one-half pint of benzole (solvent naphtha 160 deg.) to the gallon of paint, mixed as usual, will assist the paint to penetrate the pores of the wood more deeply and gain a better anchorage. Add the benzole to the priming coat only immediately before brushing it on. It evaporates rapidly.

OLD SURFACES

Old surfaces to be repainted may likewise be divided into two classes for convenience, and here again the painter, like the doctor, must analyze. He must look carefully to see what is needed before he can intelligently prescribe the treatment.

One kind of surface is that which has always been painted with pure white lead and pure linseed oil, and simply has become discolored from smoke and dust. The oil has worn out pretty well, and after dusting off the building is ready for repainting with no additional trouble or expense. The old paint will soak up oil from the new and thus renew its binder and anchorage in the pores of the wood. Usually two coats of paint, mixed fairly thin and yet sufficiently heavy to cover well make a nice job under these conditions.

The other kind of an old surface to be repainted is the one upon which hard, inelastic paint has been used. Then even if the old paint is not cracked and scaled, it is usually too hard to be penetrated by the oil of the new coat and consequently the new coat of paint merely lies on the surface and must depend upon the old paint for its anchorage; it can not anchor itself in the pores of the wood.

FALLING LINE SYSTEM OF HANDRAILING

A PROBLEM WHICH WILL BE FOUND OF SPECIAL INTEREST
TO BUILDERS AND HANDRAILERS—AN EXPERT'S OPINION

BY MORRIS WILLIAMS

THE problem here presented demonstrates the method of constructing a wreath rail over a side sweeping curve containing six winders at the bottom of a stairway, the wreath to have an easement meeting the newel post at a height of $3\frac{1}{2}$ in. above the nosing of the steps plus the length of the balusters.

It was shown in a previous article in these columns how the limitations of the Tangent System, owing

ditioned as the one under consideration, and that because in this system the falling line is the controlling factor.

Referring to Fig. 1 of the diagrams, it is shown in the elevation to follow the nosing with an easement at the top C' to agree with the pitch of the straight rail, and another easement at the bottom A'' , $3\frac{1}{2}$ in. above the nosing of the first step, according to the conditions stated. The method of procedure is to fix upon any number of points contained in the falling line, as shown at $g-S-M-N-Z-C'$; then project them to the plan center line of the wreath and therefrom to the plank plane, as shown by similar reference letters. These points are thereafter projected from the plank pitch to the face mold, as shown in Fig. 2, and finally become the controlling factors in the process of twisting the wreath, as shown in Figs. 5 and 6. The wreath when finished along this process cannot fail to be in agreement with the falling line originally fixed upon, as shown in Fig. 1.

Reverting to this latter figure it shows how the points referred to are projected from the falling line to the plank plane. From each one drop a line to the base line $X-Y$, and therefrom project them to the center line of the wreath as shown at $g-S-M-N-Z$.

Before proceeding further it will be necessary to fix upon a plank plane that will be the best in regard

Fig. 1—Elevation of the Steps, the Falling Line and Its Projection to the Plank Plane

to the tangents being the controlling factors, precluded the possibility of constructing a wreath that would be serviceable, and in no ways satisfactory. The best that could be done, as there shown, was to construct it in two sections.

In regard to the Falling Line System, as will be shown in the accompanying diagrams, it is not out of place to state that it is a system without limitations and beyond all restrictions. As such it is specifically adapted for constructing a wreath con-

Fig. 2—Method of Laying Out the Face Mold

to the thickness of plank for the wreath. Through the points $N-M-S-g$ upon the falling line draw lines across as shown to $n-m-S$. Continue these lines to the left so as to cut the overchord line as shown at $3-2-1-0$, and transfer the length of each to the plan chord as shown from C to 3; from C to 2; from C to 1, and from C to O , connecting the points on the chord line with those on the center line of the rail, as $3-N$, $2-M$, $1-S$, etc.

From M draw a line to 4, parallel with and equal

in length to the line $N-3$, and from 4 to 5 a line parallel with and equal to the line $S-1$.

By connecting $M-5$ a directing line is obtained that will produce the best pitched plane to secure the least thickness of plank for the wreath. It is the plan directing ordinate of the plane.

Now draw lines parallel to it from each point on the center line. The one from A will be the horizontal trace of the plane.

Draw the seat square to these lines through the

those in Fig. 5, where it is clearly indicated how each one has been determined. Bend a lath touching each one to obtain the face mold form. Make the joints at A and C' square to the guide line.

To twist the wreath a bevel is found for each section indicated by the circles. Just how they are found is shown in Fig. 3, which is a partial reproduction of Fig. 1. Draw a line parallel to the plank pitch from the center O , as shown in Fig. 3. Place the radius $O-A$ of the plan curve in the compass, fix

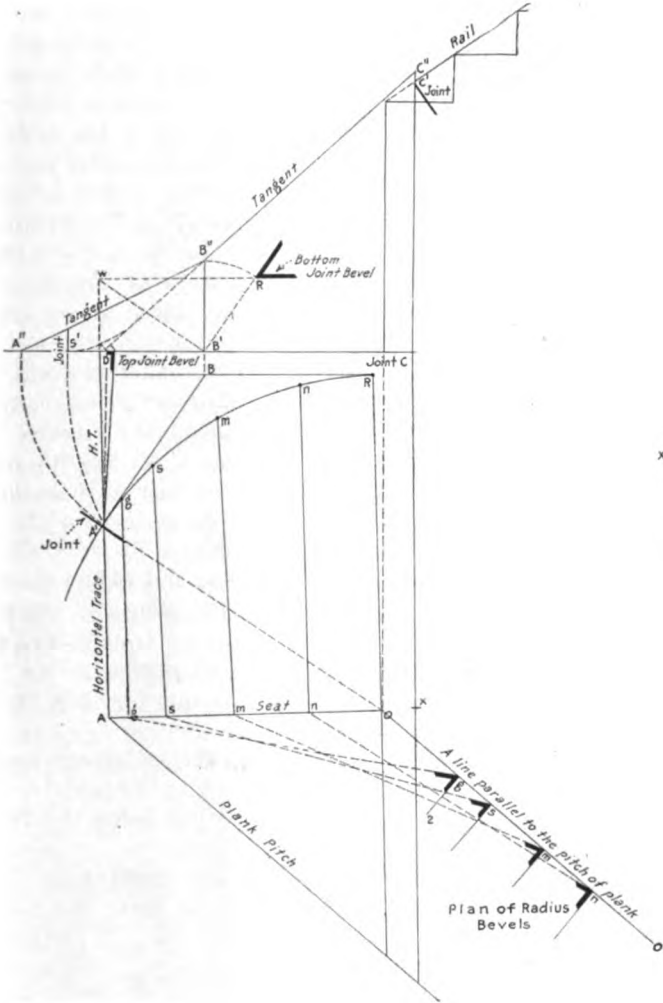

Fig. 3—Showing How to Find the Joint and Section Twisting Bevels

center O . Measure from the seat as shown from X to $G-X$ to $S-X$ to M , etc., distances equal to those in the elevation shown from X to $g-X$ to $S-X$ to M , etc., and through the points $S-S-M-N-Z-C'$ trace the dotted curved line all along as shown from A to C' . This will be the projection of the falling line upon the plank plane, the pitch of the plane being the straight line from A' to C'' .

Reproduce this line as shown at the base of Fig. 2 and proceed as follows to lay out the face mold: From each point draw perpendicular lines and place upon them dimensions corresponding to those shown from the seat to the center line of the wreath in Fig. 1. For instance, make $A'A$ equal to $A'A$, also make $u-g$ equal to $x-g$. Make $Y-S$ equal to $x-S$. Make $M-M$ equal to $x-M$, etc., shown in Fig. 1. Draw the circles in Fig. 2 as shown to correspond with

Fig. 6—Showing How to Square the Wreath

Fig. 5—Showing the Bevels Applied to Determine the Width of the Face Mold at Different Sections

Fig. 4—Finding Bevels for the Easement

one point in g upon the seat line and turn around, cutting the line from O in g . Draw a line from this point square to the line from O and the bevel will be found at g as shown.

The bevels $S-m-n$ are similarly found by fixing the compass upon the points $S-m-n$ on the seat line for the bevel required. It is shown later on, in Fig. 5, how these bevels are used to square the wreath at the points indicated on the face mold Fig. 2. The bevels for the joints of the wreath are found by a different method owing to the joints not being square to the face of the plank, the tangents or the straight rails adjoining.

To find the bevel for the bottom joint shown in Fig. 3 on the plan at A' and on the falling line at S' in the same diagram. draw a line from B' parallel with the plan joint A' to cut the horizontal trace in

W. Draw a square line to it from B' to R equal in length to $B'B''$. Connect R with W and the bevel will be found at R .

The top joint bevel is shown at D , being almost square, having been found according to the same method. Its base is the dotted line $A'D$ which is parallel to the plan joint C . Its height is a line drawn from D parallel to the top joint C' , cutting the top tangent continued as shown by the small arc at D .

The two bevels are to be applied to the joints in the same manner as the bevels in the tangent system are applied, and for the same and only purpose of twisting the wreath.

The bevels shown in Fig. 4 are for the purpose of butting the wreath joints with the square cut ends of the adjoining rails. Two bevels are found for each joint—one to be applied from the face of the plank downwards, and the other to be applied upon the face of the plank crossways.

To find the bevels for the top joint at C' Fig. 4, draw from C'' the pitch of the tangent to B'' . From the same joint draw the pitch of the straight rail to W , place in the angle at B'' the top joint bevel shown at D in Fig. 3. From W draw a line to N . Now turn the line WN to L , and the line $B''N$ to S as shown by the arcs. Connect L with C'' and S with C'' for the bevels.

The bevel at S will be the guide line for the face of the joint, while the bevel at L gives it its downward direction.

To find the same kind of bevels for the bottom joint draw the pitch of the bottom tangent $B''A''$, and from B'' a level line to R . Place at A'' the bottom joint bevel shown at R in Fig. 3 and square to the bevel draw the line $V-R$. Turn this line as shown to Z and connect Z with B'' for the bevel shown at Z , which gives the bottom joint its downward direction.

Place the compass in A'' ; open out to V ; turn around as shown by the arc and draw the tangent line to B'' for the guide line bevel. The guide lines are shown upon the face mold in Fig. 2, indicating the manner in which they are utilized in giving the true direction for the joints crossways by having them square to the guide line instead of to the tangent.

In Fig. 5 we show how the joint bevels and the plan radius bevels of Fig. 3 are utilized to square the wreath. The line $X-Y$ is an assumed center line of a plank, on which the bevel for each section of the rail is drawn. The position of each in relation to the center line is determined by the offsets, shown in Fig. 1, from the plank pitch to the projected falling line, thus making the wreath to follow the falling line instead of the center off plank, as in the tangent system. It will be seen that the center of the section shown on the joint bevel D is placed upon $X-Y$. The cause for this, shown at A in Fig. 1, is that the projected falling line does not deviate from the plank pitch.

The sections drawn upon the bevels $m-n-z$ are also similarly placed, due to the same cause. All the remaining sections are shown placed below the line $X-Y$ relatively at a distance corresponding to the

offsets between the plank pitch and the falling line, shown in Fig. 1.

The perpendicular dotted line touching the corners of each section in Fig. 5 indicate the difference in width along the face mold, as shown by the circles in Fig. 2. The diameter of each is made equal respectively to the space between these lines.

The manner in which the sections are manipulated to square the wreath is clearly indicated in Fig. 6, which illustrates the wreath material that had been sawed to form the face mold and ready for twisting.

The location of the sections in this diagram correspond with the centers of the circles shown on the face mold in Fig. 2. The manner of marking each section for twisting is shown by the figures 7-1-2-3-4-5-6 upon each section. For example, the figures shown on the end section D agree with those on the same section in Fig. 5. The figures 1 and 6 indicate points pertaining to the outside of the wreath, while 3 and 5 pertain to the inside, the shaded portions indicating the waste wood or slab to be removed in the squaring of the sides.

After squaring the sides the next step is to square the top by taking off the slab above the points 3 and 1, and the slab below the points 6 and 5 for the bottom. All sections are treated alike.

Because the markings in Fig. 6 all around are on the outside of the material—either on top, bottom or sides—the points may be easily connected by tracing as indicated in the figure by the dotted line connecting points 3 from one end to the other.

Note that by this method of squaring the wreath the sections as noted in Fig. 5 are transferred to the wreath material in Fig. 6 and precisely located so as to agree with the predetermined points upon the falling line shown in Fig. 1.

The center line of plank is not taken into account in this system as it is in the tangent, the controlling factor throughout all the operations being the falling line.

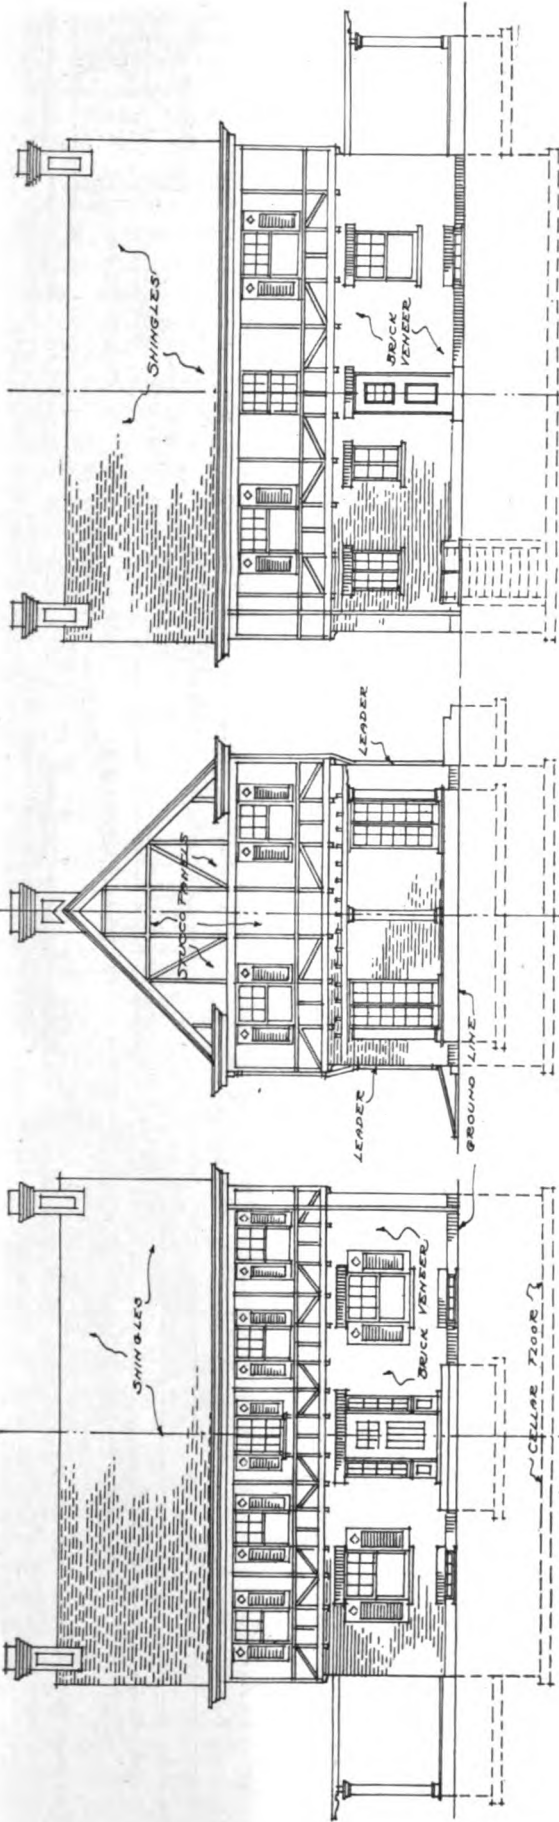

Observe that section g has been omitted in Fig. 6, due as indicated in Fig. 1 to its being too close to section D .

TO HARDEN AND POLISH SLATE

In order to harden slate there are several solutions in use on the continent of Europe. The slate is carefully analyzed and solution adjusted in conjunction with the latter's chemical properties, as otherwise if too strong the solution may easily act as a corrosive instead of a preservative. After having been treated with the solution the slate is rubbed down with sandstone, whiting, etc., and then with flour of emery, the final high polish being put on with putty powder, rouge and tripoli. Throughout the entire process great care has to be taken to insure cleanliness.

Operations have just been started on the new State Penitentiary about four miles northwest from Joliet, Ill., and to cost about \$3,500,000. The architect is W. Carby's Zimmermann, 64 East Van Buren Street, Chicago, Ill.

FRONT ELEVATION

SIDE ELEVATIONS

REAR ELEVATIONS

FIRST FLOOR PLAN.

SECOND FLOOR PLAN

ARTHUR WEINDORT, ARCHT.
LONG ISLAND CITY, N. Y.

PLANS AND ELEVATIONS OF BRICK VENEERED HOUSE SHOWN ON COLORED SUPPLEMENTAL PLATE

The trim in the living room, the dining room and the hall is to be rubbed down smooth, stained and finished flat. All floors are to be scraped smooth, varnished and waxed. The trim in the kitchen and pantry is to be painted three coats of flat white. All trim in the rooms on the second floor is to be painted three coats of flat white, and the bedroom doors are to be stained mahogany, flat finish.

The glass in all doors and windows is to be double-thick American of the best quality. The hardware throughout is to be of a dull bronze finish and of a standard make.

In the unfinished attic is sufficient space for two good-sized rooms should the owner desire, this being accomplished by cutting dormer windows in the rear of the main roof.

The exterior woodwork is to be given three coats of white lead and linseed oil. The sheet-metal work is to be painted two coats of red lead on both sides.

The house is to be piped for gas, and all rooms are to have outlets for gas fixtures. The rooms

are to be provided with electric lights, and each closet is to have a single light. The outlets are to be so arranged that combination gas and electric fixtures can be used.

The building is to be heated by a hot-water system, with radiators located in all rooms and to have a bronze finish. The boiler and radiators are to be of such size as to maintain a temperature of 70 deg. when the thermometer registers zero outside.

The architect gives the cubical content of the house as 34,683 cu. ft., and a unit price of 19c. per cubic foot. These figures, however, do not include the contractor's 10 per cent profit. He states that by substituting cedar shingles for asbestos, hot-air heating for the hot-water system, and omitting either electricity or gas, a saving of some three hundred dollars may be effected.

The architect of the house here illustrated and described is Arthur Weindorf, Long Island City, New York, or care THE BUILDING AGE, 50 Union Square, New York City.

PERFORMANCE OF BUILDING CONTRACTS

WHO BEARS LOSS UNDER DEFECTIVE PLANS?—HOW DOES DEFECTIVE PERFORMANCE AFFECT THE BUILDER?

BY ARTHUR L. H. STREET

THAT the law is uncertain as to whether a contractor can recover for work done in compliance with the governing plans and specifications but destroyed through inherent weakness of the plans as furnished by the owner's architect, is shown by a very recent decision of the Arkansas Supreme Court in the case of *Monk & Ritchie v. Pine Bluff Hotel Company*.

Plaintiffs built for defendants a six-story hotel building at a contract price of \$170,000. Suing for a balance due and for the price of extra work, plaintiffs claimed \$3,500 for rebuilding a retaining wall which fell before completion of the building. It appears that the wall fell a second time and that defendant owner caused it to be again constructed, for the cost of which a counterclaim was interposed. The evidence at the trial raised an issue of fact as to whether the contractors built the wall according to the plans and specifications and as to whether the fall was caused by defects in the plan or by faulty construction.

The jury found in favor of the contractors, under instructions by the trial judge to the effect that the contractors were not entitled to recover for rebuilding the wall unless they proved that the wall was constructed according to the plans and with reasonable skill; that the fall was caused by a defective plan, and that the defects were not such that

the contractors should have discovered them in the exercise of ordinary diligence.

On appeal, defendant complained that these instructions did not correctly state the law; but the Supreme Court held that they "were as favorable to defendant as it could ask," thus intimating that they may have stated the law too broadly against the contractors.

CONFLICTING AUTHORITIES CITED

The higher court said: "Counsel for defendant rely principally upon two Texas cases, which hold in effect that one who enters into a contract to construct a building without requiring from the other party a guaranty of the sufficiency of the plan and specifications cannot relieve himself of liability for failure to complete the work by reason of defects in such plan and specifications. In other words, that if the contractor follows the plan and specifications, which prove defective and cause the building or the improvement to fall before completion, the loss is upon the contractor and not upon the owner. *American Surety Co. v. San Antonio Loan & Trust Co.*, 98 S. W. 387; *Loneragan v. San Antonio Loan & Trust Co.*, 101 Tex. 63, 104 S. W. 1061, 106 S. W. 876. Those cases sustain the contention of counsel, but they do not appeal to us as being correct, and they are clearly against the weight of authority on that subject. The rule is, we think, clearly laid down as follows:

"Where the builder performs his work strictly in conformity with plans and specifications, he is not liable for defects in the work that are due to faulty structural re-

quirements contained in such plans and specifications, and may recover under the contract, unless he has warranted that the plans and specifications are correct." 6 Cyc. 63; MacKnight Flintic Stone Co. v. The Mayor, 160 N. Y. 72, 54 N. E. 661; Bentley v. State, 73 Wis. 416, 41 N. W. 338; Huetter v. Warehouse & Realty Co., 81 Wash. 831, 142 Pac. 675.

"The New York court, speaking through Justice Vann in the case cited above, said:

"The fault of the defendant's plan should not prevent the plaintiff from recovering payment for good work done and good materials furnished precisely as the defendant required."

An independent point involved in the Arkansas case reviewed above was decided against the contractors. It related to the validity of a provision in the contract making the builders liable for \$100 for every day of delay in completing the building. The clause was held not to require payment of so excessive damages as to amount to a stipulation for the payment of an unconscionable penalty in view of the facts that the hotel building constructed involved an investment of at least \$350,000 and that the delay complained of involved loss of several hundred monthly in rents, salary of the hotel manager, etc. On this point the court said:

"When we place ourselves in the position of the parties when they made the contract, it is easy to see that they had damages in contemplation which were not easily ascertainable, and that they elected to agree upon the damages in advance. This they had a right to do, and there is no reason why the court should disturb that agreement and arbitrarily say that the contract was one for a penalty."

WHEN LIEN RIGHT IS LOST

In a decision which is instructive on the rights of a contractor to enforce a mechanic's lien on the theory of a substantial performance of his agreement, notwithstanding minor defects, for which allowance may be made to the owner, the Appellate Division of the New York Supreme Court lately held in the case of Witt v. Gilmour that a building contract is not necessarily to be regarded as "substantially performed" merely because defects in performance involve less than 10 per cent of the contract price. In this case plaintiff was denied the right to a lien because it appeared that departure from the specifications concerning a chimney created a fire hazard, that defects in the foundations rendered the wall unstable, and that joists and rafters were set several inches farther apart than required by the contract.

Under these circumstances the court applied a former decision of the Court of Appeals to the effect that a builder has no right to substitute his own judgment for that expressed by the owner in the contract as to kind of materials to be used and the manner of their laying, especially when the strength and durability of the building is affected. "Having departed from the agreement," says the Court of Appeals, "if performance has not been waived by the owner, the law will not allow the contractor to allege that he has made as good a building as the one he engaged to erect. He can demand payment only upon the terms of his contract, and if the conditions on which payment is due have not been performed, then the right to demand it does not exist."

It appears that in the case cited above the defective work was performed by sub-contractors; but the court holds that the general contractor, having assumed the principal contract, is chargeable with

their shortcomings, especially where he also assumed to supervise the construction.

FAILURE TO CONSTRUCT A FLOOR ACCORDING TO CONTRACT

The measure of an owner's recoverable damage for failure of the builder to conform to contract specifications in the erection of a building was considered by the Wisconsin Supreme Court in the case of Bucholz v. Riemenschneider, wherein an owner complained of the substitution of a felt or asphalt paper roof instead of the tar and gravel roof contracted for, and complained that a cement floor was not up to specifications.

The court applied the following rule applicable to defective construction in general: If the defect can be remedied without reconstructing a substantial part of the building, or without great sacrifice of work and material already wrought into the building, the reasonable cost of correcting the defect should be allowed against the contractor; otherwise the proper measure of the owner's damage is the diminished value of the building, on the basis of the contract price, by reason of the defect. Removal of a felt or asphalt paper roof and substitution of a tar and gravel roof of the kind called for by the contract being readily accomplished without any reconstruction of the building, the court finds that the cost of the substitution is the proper measure of damages as to this item. But since it appears that the floor in question could not be made to conform to the contract without reconstruction of a substantial portion of the building, it was decided that the owner's damage in this respect is to be computed according to the diminished value of the building resulting from the builder's failure to construct the floor according to contract.

MANUAL TRAINING WORK IN A MICHIGAN SCHOOL

The value and utility of manual training in connection with public-school work is recognized and its various branches are being gradually introduced into the curriculum of numerous schools. A notable example of what boys can do along these lines is shown in the work of the students of the High School at Ishpeming, Mich., for they repair the school buildings for pay, conduct a co-operative school farm for profit, and are about to erect a gymnasium for their school from plans drawn by seniors. All this work is under the direct supervision of the regular school authorities, according to H. W. Foght of the United States Bureau of Education.

High-school students from the manual-training department have been employed to repair the various city school buildings for the past six years. During one summer the students thus earned \$3,000. The boys have repaired roofs, laid cement floors, built brick walls, and installed plumbing fixtures.

The reports of building operations thus far the present year, taking the country as a whole, indicate a striking demand for residence construction.

Trade Topics—Every Reader is Invited to Participate

REMODELING AN OLD DOORWAY

From John Wavrek, Jr., Pennsylvania.—In looking over recent issues of *THE BUILDING AGE*, I noticed quite a number of engravings of very attractive entrances to residences, and the prominence given to this feature has led me to believe that sketches and a description of the way in which a commonplace entrance was remodeled into one of handsome appearance would be of interest. The remodeling was done at small cost, the owner originating the design and executing it himself during spare time.

In the original entrance, shown in Fig. 1, the wall was of brick, the door frame of white pine, and the door itself of chestnut. The finish of the

Almost any entrance can be similarly transformed by a good mechanic if he studies the requirements of the job to be done and takes care not to make it bizarre or out of place.

DISCUSSION OF BUILDING METHODS

From D. P. Barry, Clinton County, New York.—I have carefully read what "J. P. W." of Lane, Kan., has to say about sill No. 1, as described by me in the July issue of the paper. The form of sill there presented was intended to show a method of construction widely prevalent in Kansas when I reached the Sunflower State, and when

Fig. 1—Elevation of the Original Entrance

Fig. 2—Appearance of Doorway After it Has Been Remodeled

Fig. 3—Cross-Section and Details of Capitol and Base

Fig. 4—Vertical Section Showing Construction of Head

present doorway, Fig. 2, is chestnut, the frame being veneered. The new design certainly adds materially to the value of the house.

The jambs were treated as shown in the cross-section, Fig. 3, and it should be noted that cement blocks with a rough-stone face were used in the construction of the building. The vertical section, Fig. 4, shows the construction of the cornice, which is built against the bottom of a bay window located directly over the doorway.

I was about half way through the teens. It was in use when I left as well as before I arrived. I intended it to show cheapness of construction in Kansas. Many houses were built without studs, but with what might be called plates, the boarding running vertical—no plaster or clapboards. Some houses were clapboarded on the studs without sheathing or plaster. When I said "each side," I obviously meant four sides. I was fresh from school when I went to work on that sill, and,

though I did not know much about building, the contractor kept me on until work shut down late in the fall.

I would say that I never saw a rotten sill in Kansas except when set on the ground or on a small stone or piece of wood. The climate here is far wetter than Kansas, and timber sills rot from three causes, namely: setting on the ground after digging one side down to the level, an old custom quite common; second, having no roof over the front doors, the sills of which were cut between the casings and flush with them; and third, leaving banking up year after year. The sills, in these cases, could not dry out. Few houses in Kansas had cellars, and fewer cellars were walled up. The sills might rot in some of these cases, but the statement that sills will rot because doubled up is not in accord with my experience. Might I ask what is the difference in that respect between No. 1 and No. 2? Old buildings called block houses and barns, built in this section, of timbers hewn on four sides, can be seen all about here that have been built nearly a century, and are yet sound where they have been kept out of the ground. In the article in a recent issue, on barn construction, by W. E. Prudden, he shows he is not afraid of doubled plank rotting.

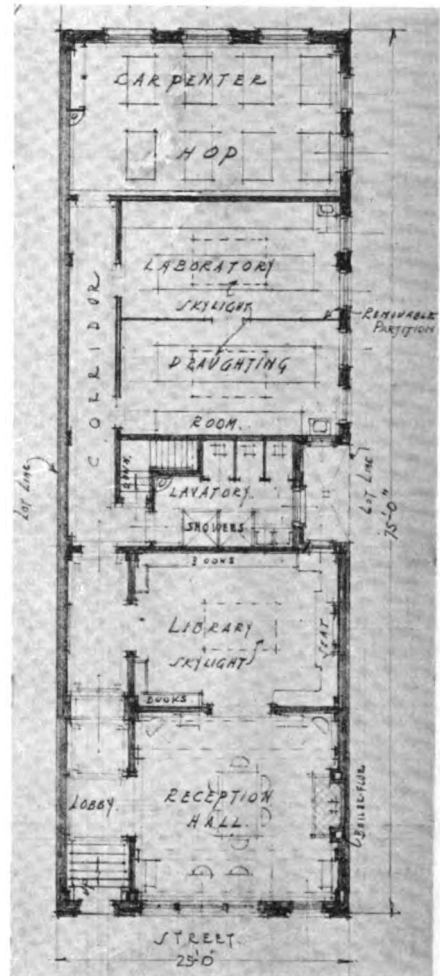

There is nothing to be gained in having the pieces cut between the joists in No. 3, touch the studs. There is nothing to prevent any one from setting them against the studs if he prefers. They are not put in for the purpose of nailing the joists to them. Bridging will not take joists out of wind nor keep them out unless the ends are securely fastened. Studding placed on top of the sills give a rigid construction. If a cyclone takes the superstructure, the floor will be left, at all events.

Now in regard to the door sill. There are similar sills in my own house, which was built some sixty years ago, and they are scarcely marred except those of the woodshed and kitchen doors, which have been trampled on with the heavy cowhide, hobnail boots of those days. Two hours' work will render them good for another century. The style I presented is made of hard wood, and is inconvenient to step on. People always step over the threshold, and the man who puts it in, however young, will not live long enough to ever be called upon to repair it. On page 67 of the September issue a similar sill is illustrated. In that type one must set it with exactness, so that the floor will slip under the lip, and one cannot use flooring of a thickness different from that for which it is set.

Now, a few more words about sawhorses. According to my notion, 2 x 4-in. makes satisfactory horses for sawing long material or other work requiring a pair. However, in clapboarding, where only one is used, 2 x 4 is a nuisance, for as soon as you are ready to square, the board tumbles down; you go to get a measure, and it tumbles again. All work of that character requires a 2 x 6-in. or 2 x 8-in. What is better still, are 3-in. or 4-in.

FLOOR PLANS FOR TECHNICAL CLUB HOUSE

From Charles G. Hehn, Architect, Yonkers, New York.—I am sending herewith a sketch showing a floor plan arranged for a technical clubhouse which may meet the requirements of "S. C. M.," Lake Hopatcong, N. J., whose request appeared on page 56 of the September issue of the paper. He did not state whether or not the lot was on a corner, or how situated as to yards, adjoining buildings, etc. The design which I send will, I trust, prove of interest to the correspondent. The sky-

FLOOR PLAN FOR A TECHNICAL CLUB HOUSE

lights shown will, I think, give sufficient light and ventilation. If, however, there are any points concerning the layout which are not fully understood, I shall be glad to furnish the desired information through the columns of the paper on request.

A QUESTION IN "BATTERED" FRAMING

From C. J. M., St. Johns, N. F.—There appeared in an issue of the paper some time ago a communication from "J. F. M.," Los Angeles, Cal., asking for information regarding the proper cuts at the foot of the posts of a tower the walls of which inclined both ways. When I noticed this question at the time of its appearance I thought it such a

simple matter that it was hardly worth writing about. Since then, however, several very unsatisfactory answers have appeared, and I am, therefore, constrained even at this late date to give the method which I learned for doing such work. Now, as there would be no difficulty in getting any cut on the intermediate posts which stand at right angles to the plane of the sides of the structure, I assume it is with regard to the corner posts that the correspondent requires information.

The question may be generally treated under the head of "battered framing," that is, the framing of structures with walls inclined inward so that they approach each other at the top, thus making the top smaller than the bottom. This is the case with the frames which support water tanks, windmills, bell towers, etc. An elevation of one side of such a structure is shown in Fig. 1 of the sketches, with an outline of the plan in Fig. 2.

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Fig. 6

pendicular to the sill, will coincide with the sides of the sill, as shown by the section *a-b-c-d* in Fig. 3; but after it is cut to the proper bevel to fit against the sill, the section cut out at the foot will be diamond shaped, as shown at *a-b-c-d* of Fig. 4. Here it will be noticed that the faces *a-b* and *a-d* of the post do not coincide with sides of sill *a-* and *a-g*.

It is not necessary that the outside faces of the corner should coincide exactly with the planes of the sides of the structure if it is merely a frame-work; in this case, posts of square or rectangular section may be used. If, however, the frame is covered in, the posts must be backed so as to receive the boarding. The backing consists in shaping the post so that when the bevel is cut at the foot the section cut out will be similar to that shown at *e-b-c-d* in Fig. 6. The backed post must then be set on the sill so that the point *e* will be at the corner *a*. Then the outside faces of the post,

SOLUTION PRESENTED BY "C. J. M.," ST. JOHNS, NEWFOUNDLAND

It will be seen that the corner posts *a-a* are not perpendicular to the sill at the bottom, but are inclined, and approach each other at the top. This means that the foot of the post must be cut on a bevel where it is tenoned into the sill and the bevel must be cut diagonally across the post from corner to corner, since the post inclines diagonally toward the center and is set so that its outside faces coincide approximately with the planes of the sides of the structure, as indicated in the plan view, Fig. 4. A special cut is also required for the ends of the girts, *b*, of Fig. 1, where they are framed into the posts, which is obtained by taking the angle of the lines *b-c* and *d-c* of Fig. 4 with the face of sill for the top cut and the pitch of post for side cut.

The outside faces of the post, if standing per-

e-b and *e-d*, will coincide with the faces of the sill, *a-f* and *a-g*. If the post has a plumb cut at the top, it should be backed before the bevels are cut, because backing them afterward would shorten the distance between bevels. A square post will have, after the backing is done, a peculiar rhombus-shaped section, as at *i-j-k-l* of Fig. 5. Here, *h-i-j-k* shows the original square section which is taken square across the post, perpendicular to its edges.

In Fig. 7 is illustrated the method by which the amount of backing necessary in any particular case may be determined.

If the post were set up perpendicular to the sill, the plan of it would be *a-b-c-d* of Fig. 7. Draw indefinitely the dotted lines, *a-p*, *d-s* and *c-q*, at right angles to the diagonal line, *a-c*, of the plan.

This gives a diagonal elevation of the post. Now, at any convenient place draw the line $j-l$, which should be the diagonal bevel of the foot of the post where it stands on the sill. The center of the line $j-l$ is the point n , where it cuts the dotted line $d-s$. Through this point, perpendicular to $j-l$, draw $i-k$, making $n-i$ and $n-k$ equal to $f-b$ and $f-d$ of the plan. Join $i-j$ and $k-l$, which will show a section of the square post when cut to fit the sill. Make $n-m$ equal to $n-i$ and $n-k$; draw $m-k$ and $m-i$, which shows the amount of backing as it appears on the bevel cut. Draw the dotted line $m-e$, cutting the diagonal line $a-c$ of the plan in the point e . Join $e-d$ and $e-b$, then $a-e-d-b$ is the amount of backing to be taken from the square timber so that the outside faces of the post will coincide with the planes of the sides of the structure after bevel is cut.

In Fig. 8 is shown the method of obtaining the bevel cut at the bottom of the post to make it fit the level plane of the sill. Having drawn the lines $o-p$, $q-r$ and $s-t$, representing the corners of the post, next draw the line $u-v$ to represent the plane of the sill. Draw also through the point u where $u-v$ cuts $q-r$, the line $u-w$ at right angles to $q-r$.

Now, taking the section $i-j-k-l$ of Fig. 7 for the beveled section of the post, we find that the corner, l , is longer than the corner, j , by the length of the line $v-w$ of Fig. 8, and that the corners i and k are longer than the corner j by the length of line $x-y$.

Therefore, if we square a line around the post, as $a-b-c$ of Fig. 9, and lay off $c-d$ and $b-e$ equal to $w-v$ and $x-y$ respectively, we have, on connecting $a-e-d$, the bevel of the end of the post taken from the square timber when it is required to be backed.

If the outside faces of the post are backed so they come within the plane of the sides of the structure, the bevel may be easily obtained by the steel square, applying it to the post, as shown in Fig. 10, with the rise on the blade and the run on the tongue, and drawing a line by the tongue.

In a later issue of the paper, "G. F. Smith" gave a somewhat mystifying solution to this problem. He presented a mass of geometrical pedantry about horizontal and vertical planes of projection and talked about trigonometry and tables of sines, tangents, logarithms, etc., which is about as intelligible to the average working carpenter as a Chinaman's laundry check. He also said he had been reading most of the leading building journals for the last twenty years, and that this was the first occurrence of this problem in any of them, and that he heard it discussed as a catch puzzle, etc. If the correspondent in question will kindly turn to page 212 of the June (1909) issue of *Carpentry and Building*—that being the name of the paper at the time—he will find a similar problem discussed; in fact, the very same problem, with a different application. If he will take up the text-books of any of the trade schools, he will find the question of battered framing discussed at length. For my part, I do not believe that the present problem was put forward as a catch puzzle. I think it is a real live question, and ought to be treated in a manner so plain that it will be understood by the average mechanic.

STUDDING SOCKETS FOR CONCRETE WALLS

From W. E. F., Charles City, Iowa.—It is a well-known fact that wooden sills bolted to concrete walls have not always given entire satisfaction, and neither have they been of long life. Very often this condition of things has resulted in the weakening of the building at a very vital point, so much so as to wreck the entire structure. Cast-iron studding sockets can now be obtained which

STUDDING SOCKETS FOR CONCRETE WALLS

may be imbedded in the soft concrete in such a way as to produce a hundred-year post support. The sockets are set every 2 ft. along the walls, or whatever the spacing may be for the building. The studding can then be set into them and spiked in place. Such a connection between the concrete base of the building and the frame walls is everlasting and worth while. The picture which accompanies these comments clearly shows the idea.

TROUBLE WITH GLUED-UP WORK

From J. M. D., Detroit, Mich.—I noticed in one of the recent issues of *THE BUILDING AGE* that a reader wanted to know the reason why his glued-up work was not straight after he had taken off his clamps. "W. M. D." of Baltimore, Md., gives a pretty good reason in the September number, but he could go a great deal further. He says the boards should be straight from end to end. I do not agree with him there for this reason, he will find after taking off his clamps that sooner or later the ends will open up. I have been in the gluing business a great many years and experience has taught me many things. The best test I have had was when I was in the employ of a concern in Kalamazoo, Mich., gluing tops and backs by the thousand.

The first thing to do is to make sure that the stuff is dry. Next join the stuff with a slight hollow; put on a clamp, pull up, watch carefully to see that every place touches and if so all right, then take a toothing plane and tooth both edges. Now we are ready for the gluing.

I notice that "W. M. D." says to have the glue thin. That is all right for some things, but not for all close grain wood. I always temper the glue for

the kind of wood. The job I had was in connection with work where they carved the tops concave and convex to 3/16 in. thick from 3/4-in. stuff to get the swell.

"W. M. D." is all right in regard to putting on the clamps on a bow, etc., but he should have his stuff warm on the edges so as to keep the glue from setting. Be sure to squeeze out all the glue until the work is wood to wood. If he follows this he will never have any trouble with his work.

MITERING A RAKE AND LEVEL MOULDING

From W. M. L., Orange, N. J.—Will some of the practical readers of the paper tell me how to miter a rake with a level molding for an exterior angle, the rake having a fall of 1 in. to each foot of length? It is a fillet molding 2 in. wide for face. I would like to see a diagram, with full explanation.

Note.—Some little time ago the problem was illustrated and described at considerable length, and in a way to be of special value to the readers, but as it is possible our correspondent has no files of THE BUILDING AGE running back several years, we submit the question for the discussion of those readers who may be interested.

PLANS WANTED FOR BAKE OVEN

From H. E. McC., Springfield, Ohio.—I would like some of the readers who have had experience in the building of bake ovens to send to the editor for publication a sketch of one burning coke. I have worked on three, but had no chance to see how the most complicated and important parts of the flues were laid out, as the ovens were patented and the foreman would not allow us to touch them, he doing this part himself.

As I have one to build, I would appreciate any sketches, plans or suggestions along this line.

APPLYING SCAGLIOLA TO CEMENT

From E. M. K., East Dowingtown, Pa.—I come to the correspondence columns for some information in regard to scagliola. Will it hold on cement and how is it applied and colored? Would it be used the same way as on cement composed of lime, mortar, hair, plaster of Paris? The job is in the chapel of a church in Dowingtown and the work was done in the winter. A lot of creek sand was used and when the forms were taken off the work was very rough on account of the sand.

If some of the readers can help me out I will try and make a better job for the church on my own time for the church needs all the help it can get. As I did a great deal of the work, I feel that it is only right for me to make the job as satisfactory as possible. I understand putting on a plaster wall and am not up on scagliola.

I have been a carpenter for ten years and have read THE BUILDING AGE ever since the time I began to work at my trade.

RUSTIC FOUNTAIN AND WATERING TROUGH

From Observer, Chicago, Ill.—I believe many of your readers will be interested in the novel bubbling fountain and horse trough that was built in Brookfield, Ill., by Conrad Schneider, a contractor and builder of Congress Park, Ill. The structure represents an investment of less than \$200, and the different colors in the field stone used in its construction present a very pleasing appearance.

The base of the fountain is 4 ft. 6 in. wide and 8 ft. 6 in. long, and above the field stone is a concrete trough nearly 3 ft. long and 8 in. deep. On the far side is a bubbling fountain, beneath which

A RUSTIC FOUNTAIN AND WATERING TROUGH

is a cobblestone step for children. An economical feature is that all waste water from the bubbler flows into the trough under the archway gracing the center of the structure. The fountain is capped with cut stone, and flowers adorn the top, while it has also been piped for gas and wired for electric lighting.

The work is an excellent example of what may be built for a small cost, where slightly defective stones, or seconds, are used; and an ingenious arrangement of the various stones is something which the contractor can point to with pardonable pride.

A NOTABLE HOUSE MOVING OPERATION

A THREE-STORY DWELLING WEIGHING ABOUT 375 TONS SUCCESSFULLY CARRIED DOWN A STEEP HILL

WHAT is said to have been the largest and heaviest wooden house ever moved in the city of San Francisco has just been transferred to a new site, a picture of the operation at one of its stages being presented herewith. The house was 58 x 50 ft. in plan, three stories in height and weighed something like 375 tons.

Although its journey involved a distance of only two city blocks, a part of its route was down the steep hill of Washington Street between Octavia and Gough. Going down the hill a dozen men were

down the steep hill was accomplished in a week-end while the entire journey was completed in four weeks, which is said to establish a record for moving houses of a similar size and weight.

The picture which we present was taken especially for *THE BUILDING AGE*, and affords a good idea of the manner in which the house was supported upon the cribbing of timbers.

When the journey began Foreman T. L. Hunt, who superintended the moving operation for contractor William Haskins, put a tag on every crack

A VIEW OF THE BUILDING AFTER IT HAD BEEN RAISED FROM ITS FOUNDATIONS

employed although for the greater part of its travels the house was accompanied by a crew of only 6 men.

In order to serve as a "brake" in its trip down the hill a "Chinaman" was used—not a native of the Celestial Empire, but a heavy wooden post sunk deep in the ground and to which heavy hawsers were fastened. The work was pushed as rapidly as possible so as to avoid blocking the street cars any longer than was absolutely necessary. The trip

in the building so that he might be able to tell exactly how much the structure would be affected by the trip. When the journey was finished a careful inspection of the house showed only four new cracks, and these were of minor importance.

The National Paving Brick Manufacturers' Association will hold its annual business meeting Oct. 5, at the Deming Hotel, Terre Haute, Ind.

A COTTAGE OF SHINGLED EXTERIOR

THE MASTER'S ROOM AND BATH ON FIRST FLOOR
ARE FEATURES — DETAILS OF CONSTRUCTION

THE cottage here illustrated is a combination of brick, stucco and shingles, with large overhanging roof. The low, broad proportions, simple roof lines, the attractive grouping of the windows and the wide veranda extending entirely across the front of the building, all make for a most pleasing exterior. The open arrangement of the library, living room and dining room with their large windows gives an effect of spaciousness which is unusual. The library is fitted with book cases

and a commodious tiled bathroom and on the right with the dining room and kitchen.

A feature of the first floor hall is a large linen closet so placed as to be readily accessible.

The kitchen is well arranged, having every modern convenience including gas range, dresser, pot closet and flour and meal bins. The broom closet is an added feature which appeals to the thrifty housekeeper.

The water boiler in the kitchen is connected to a

SHINGLED COTTAGE OF E. W. BILL AT HAWORTH, N. J.—ARCHITECT, J. L. THEO. TILLACK, NEW YORK CITY

and window seats, and the French doors between the two rooms add to the effect while affording greater privacy when such is desired.

The living room with its open fireplace of brick and its tile hearth together with the window seats on each side tend to produce a cozy, comfortable and homelike interior. A feature of the dining room is the built-in buffet and window seat. The wide hall extending from the library to the stairway connects on the left with the master's bedroom

gas water heater and also with a Berkshire heater attached to steam piping so that water can be supplied by the heating plant when in operation, thus creating an economical system of hot water supply.

On the second floor are three large bedrooms and bathroom, together with maids' room, each opening into the central hall. All bedrooms have large clothes closets and there is a large space which can be used for storage purposes as shown on the floor plan. The space under the roof above the second

floor bathroom is ventilated with louveres in each gable end.

The cellar which extends under the entire house is well lighted and contains the laundry, extra toilet, coal bins and steam heating plant.

The foundation walls of the cottage are of con-

crete and two parts sand. The floor is graded to a drain under the floor consisting of a dry well filled with loose stones. The soil in the section where the cottage was erected is sandy, thus allowing the water to readily seep through.

The outside of the foundation walls below grade

Front Elevation—Scale $\frac{1}{8}$ In. to the Foot

Second Floor—Scale $\frac{1}{16}$ In. to the Foot

crete mixed in the proportions of one part Portland cement to two parts clean, sharp sand and four parts gravel. The cellar floor is of concrete, 3 in. thick, mixed in the above proportions, with a top dressing about 1 in. thick consisting of one part

were painted with two coats of Barrel's waterproofing paint.

The exterior chimney is built of Hackensack hard-burned brick and faced with light colored wash brick selected from outside the kiln. The same kind

of brick was also used with good effect in connection with the porch columns.

The chimney, as will be noted from the detail presented elsewhere, takes care of the living-room fireplace. An ash dump in the hearth carries the ashes into an ash pit which is provided with iron

coat work with sand finish, thus giving an ideal surface for tinting.

The bathroom on the main story has tiled floor and side walls, the tile floor having a concrete base laid on centering between floor beams.

All areaways around the cellar windows have

Detail of Bracket—Scale 1/2 In. to the Foot

Section Through Porch Rail—Scale 1 1/2 In. to the Foot

Elevation of Verge Rafter—Scale 1/2 In. to the Foot

Side (Right) Elevation Showing Outside Chimney—Scale 3/32 In. to the Foot

clean-out door at the cellar floor level. A trimmer arch of brick supports the fireplace hearth which is finished with red Welsh quarried tile. The back of the fireplace as well as the sides have firebrick lining. A Covert throat damper connects the fireplace with the smoke chamber and terra cotta flue lining.

All rooms throughout are plastered with three-

brick walls with porous brick bottoms laid dry. Framing timbers are of spruce, the sills and posts being 4 x 6 in. and the studs 2 x 4 in. placed 16 in. on centers. The plates also are 4 x 4 in. The girders in the cellar supporting the first floor joists are of spruce 6 x 8 in., resting on 4-in. lally iron columns filled with concrete. The first and

second floor joists are of 2 x 10 in. spruce placed 16 in. on centers and the ceiling beams and rafters are 2 x 6 in. All headers and trimmers around stair wells and openings are 4 x 10 in. All floor beams are doubled under partitions and the partitions over girders extend down to them instead of resting on top of the joists, thereby reducing shrinkage. All wide partitions are bridged once in their height with pieces of 2 x 4 in. stuff cut in horizontally.

The outside walls of the house are covered with $\frac{7}{8}$ -in. shiplap sheathing boards, over which is placed one thickness of Neponset waterproof building paper well lapped. Over this in turn are laid red

It will be seen that the second floor projects over the front veranda. This is supported by two columns with two steel channel bars with iron column from brick pier to underside of the second floor. This method was used so that the weight of the floor beams and building would be taken up properly and prevent the front second story wall from sagging in the center. This construction is shown in the details on another page.

The porch floors were laid with $1\frac{1}{4}$ x 3 in. tongued and grooved cypress embedded in white lead with floor timbers of 2 x 8 in. spruce.

First and second floors have $\frac{7}{8}$ x 8-in. tongued and grooved under flooring well nailed to each bear-

Perfection cedar shingles exposed $5\frac{1}{2}$ in. to the weather. All shingles were dipped in creosote shingle stain at least two-thirds their length before being laid.

On the rafters were laid 1 x 2 in. shingle lath to carry the red Perfection cedar shingles, which were exposed 5 in. to the weather and which were fastened in place with zinc-coated nails. All overhangs on the roofs were laid with 1 x 6 in. matched beaded white pine well secured to the building and nailed on the second rafter from the face of the building so as to properly stiffen it. In addition to this, large brackets were nailed to the sides of the building to support the verge rafters.

ing and with joints broken on bearings only. The flooring is fitted tight up against the outside sheathing and over it was placed one layer of building paper. On this in turn was placed the finish floor of $\frac{7}{8}$ x 3-in. tongued and grooved comb grained pine except in the kitchen where $\frac{7}{8}$ x 3-in. tongued and grooved maple was laid.

All windows have stock frames of white pine with pulley stiles and parting strips of hard pine. The sills are rabbeted and of 2-in. stock. All double hung sashes are provided with Silver Lake sash cord and balance weights.

All interior doors on the first floor are of chestnut, of the one-panel type. The front and rear out-

side doors are of white pine, painted. All doors on the second floor are of birch and are $1\frac{1}{2}$ in. thick of the two-panel type.

The chestnut trim on the first floor is stained and waxed and the whitewood trim on the second floor is finished white enamel with two-panel birch doors finished natural. The steam heating plant has an American Ideal boiler and radiators. All

in old buildings by the office holder, and during hot weather the refreshment attending a shower bath better qualifies him for the exacting services required. Recognition of their value is being shown in the plans of new buildings in various centers. The new county-city building of Pittsburgh, Pa., provides a private bath of the shower type in the lavatories for the heads of all departments and

Vertical Section Through Fireplace Showing Construction—Scale $\frac{1}{4}$ In. to the Foot

pipes in the cellar are covered with air cell sectional asbestos covering, and the boiler is covered with asbestos cement.

The house here illustrated and described was erected at Haworth, N. J., for E. W. Bill in accordance with plans and specifications prepared by Architect J. L. Theo. Tillack of 150 Nassau St., New York City.

The contractors executing the work were the Commonwealth Building Company, 50 Church Street, New York City.

PLUMBING IN PUBLIC BUILDINGS

The advantage of having shower baths in addition to the usual sanitary conveniences in buildings used by public officials has been demonstrated in many instances. Such provision has been made

similar equipment in the lavatories used by the employees. This is in harmony with the equipment now provided in first-class hotels where the traveling man has had his demands satisfied in the provision of a shower bath in his room, even in some cases to the exclusion of the bathtub.

COLLECTION OF FOREIGN AND DOMESTIC WOODS

What is probably the best collection of foreign and domestic woods in panel form in this country is now being installed on the second and third floors of the new Forestry Building of the State College of Forestry at Syracuse, N. Y. For the past two years search has been made throughout the country for available commercial varieties of wood native to this country, as well as the important commercial

woods from South America, Mexico, the West Indies, Africa and the East Indies.

Among the rare foreign woods that will be displayed as panels around the rotunda in the College of Forestry Building are African gaboon, East India koa, marblewood, East India rosewood, satinwood, camphor wood, teak, Circassian walnut and eight different kinds of mahogany. Among the western woods of this country displayed are Douglas fir, California redwood, sugar pine, Western yellow pine, Sitka spruce, Port Orford cedar, incense cedar and several varieties of eucalyptus. The Southern forests are represented by cypress, Southern hard pine, North Carolina pine, red and black gum, cucumber and persimmon. A great variety of native hard and soft woods found in New York are the nucleus around which these rarer woods are gathered.

The collection of panels of native and foreign woods built into the rotunda of the College of Forestry Building at Syracuse are being finished carefully to bring out the natural grain to best effect and at the same time to detract as little as possible from the native color and natural wood fibers. Each panel is to be labeled with the common and scientific name so that both the student body of the college and the many visitors who come to the building may study a permanent exhibit of unusual interest and value. Lumber manufacturers' associations and lumbermen throughout the country have been co-operating very cordially with the New York State College of Forestry in supplying these panels.

BUILDING CONSTRUCTION IN CHICAGO

Building construction in Chicago for the month of August showed a decrease of 39.21 per cent as compared with the corresponding period a year ago. The first eight months of the year, taken in the aggregate, still show a gain of 40.55 per cent as compared with the same months in 1915. Permits were taken out in August for 758 buildings fronting 21,262 ft., with a total estimated cost of \$5,783,000, as against 995 permits, 28,870 ft. frontage, and \$9,513,150 for August, 1915. The construction of apartment buildings continues to be the feature of the operations.

OPPORTUNITY FOR FOREIGN TRADE

The American Consulate General at Paris, France, has issued a notice to American exporters calling attention to the fact that after the conclusion of peace there will be an excellent opportunity for American manufacturers to secure a goodly share of the French import trade, provided they conform to French custom in regard to quotations, terms of delivery, etc. As being of interest in this connection, René Gruet, architect, of 77 Rue Reaumur, Paris, states that the address of THE BUILDING AGE having been given him by the United States Consulate, he desires to announce to patrons of the paper that he has established, with the help of some of the best builders of Paris, an important firm for

the handling of building materials, etc., and he will be glad to take the exclusive agency for France and Belgium of one or more articles used in connection with building construction.

TENEMENT HOUSE CONSTRUCTION IN NEW JERSEY

A report just issued by Miles W. Beemer, secretary of the Board of Tenement House Supervision of New Jersey shows that during the month of August tenement house construction in that State was slightly less both as regards the number of buildings approved and the amount of vested capital involved than in the same month a year ago. A comparative statement of the tenement operations for August, 1916 and 1915, is as follows:

	1916	1915
Athenia	\$4,000
Bayonne	\$25,000	16,000
Bloomfield	5,000
Bradley Beach	8,000
Cliffside Park	15,000
Clifton	9,000	16,000
East Orange	47,000
East Rutherford	5,000
Elizabeth	40,000
Garfield	19,000	3,000
Irvington	15,000	30,000
Jersey City	195,000	107,000
Kearny	6,000
Montclair	15,000	15,000
Newark	48,000	63,000
North Arlington	5,000
North Bergen	4,000
Passaic	80,000	13,000
Paterson	25,000	11,000
Perth Amboy	6,000	12,000
Summit	4,000
Town of Union	20,000
Weehawken	150,000
West Hoboken	14,000
West New York	29,000	16,000
West Orange	12,000
Totals	\$547,000	\$560,000
Alterations	14,000	21,000
	\$561,000	\$581,000

According to this showing, Jersey City had the largest gain and Weehawken recorded the largest falling off in operations.

THE COMING COMPLETE BUILDING SHOW

Announcement has been made by Ralph P. Stoddard of the National Complete Building Exposition that the Second American Complete Building Show will be held in the Grand Central Palace, New York City, on March 5 to 11, inclusive, 1917. Plans are under way to make this much larger, more diversified and comprehensive display than was the First American Complete Building Show, held in Cleveland in February last. It will be recalled that the show is patterned somewhat after the well-known Building Trades Exposition held every year in London, England, and which has been a complete and comprehensive educator for the building industry and the prospective home owner of Great Britain and the continent of Europe.

Work on a building operation of 146 dwellings, apartments and stores, estimated to cost \$500,000, is about to be begun in Chester, Pa.

COTTAGE HEATED BY PIPELESS FURNACE

EQUIPMENT WELL ADAPTED TO THIS TYPE OF BUILDING
—ROOMS HEATED WITH ECONOMICAL FUEL CONSUMPTION

IN view of the popular reception that has been accorded the so-called "pipeless" furnace within the past year, it may not be without interest to present some particulars of a low-cost cottage in the Middle West in which this type of equipment has been installed. The work is a striking example of the adaptability of such a heating plant to this type of building and the installation should command attention both from the standpoint of economy with reference to its initial cost and to maintenance. The data will prove of special value at this time of the year—a season when contractors are busy installing heating equipment in homes that have been recently

faces west, and the rooms are so arranged that those occupied during the day receive the full benefit of the sun throughout the day. The roof is covered with dark red asphalt shingles and the dormer on the west front adds to the architectural appearance when viewed from the street.

The cellar is 7 ft. 4 in. high and well lighted by seven windows. In the northeast corner is a cistern built of concrete blocks, having an approximate capacity of 1350 gals. A view of this appears in one of the pictures accompanying this article.

The cellar floor is of concrete resting on a 3-in. bed of cinders graded toward the floor drain. The

COTTAGE BUILT BY J. C. LAWRENCE AT HARVEY, ILL., AND HEATED BY MEANS OF A PIPELESS FURNACE SYSTEM

completed or are rapidly approaching that stage of construction. The subject of the present article is a comfortable home of five rooms in Harvey, Ill., a town of 7000 people, about 20 miles south of Chicago. The completed structure represents an investment slightly in excess of \$2,000, and the furnace installed cost about \$80.

The building has a pleasing exterior treatment of stucco which harmonizes with the dark brown of the porch columns, window frames and sills, as well as other exposed woodwork. The building

mixture consists of one part Portland cement, three parts sand and five parts of stone screenings. The top finish is $\frac{1}{2}$ in. thick and contains one part cement to two parts sand, the work being properly floated and troweled.

The footings are of concrete throughout and are exceptionally heavy, being built below the frost line to prevent cracking under extreme climatic conditions. The foundation walls are of 8 x 8 x 16 in. unfaced cement blocks, forming 8-in. walls. On completion of the basement work, the inside surfaces

were treated with a wash of cement and Medusa waterproofing, while the exterior was left untouched so far as a finish coat was concerned.

The cistern was constructed as the basement walls were laid up, the same size blocks being used in both cases. As the work progressed the blocks were bonded into the walls to insure a rigid and substantial job and the hollow centers of the blocks filled with sloppy concrete. The inside walls of the cistern were given a brush coat of Medusa waterproofing when completed.

The framing is of yellow pine, the sills being 2 x 6 in., the outside studs 2 x 4 in. ribbon boards 1 x 6 in., floor joists 2 x 10 in., placed 16 in. on centers, and with a good grade of building paper placed between the rough and finish floors. Stud partitions are 2 x 4 in. doubled at all openings, the heads of the latter being well bridged and braced. On each side of the building and at either end were run two rows of 2 x 4's from the plates to the

pulp and a hard white finish coat. Outside plastering is made up of one coat of cement and lime mortar, well fibered, and a second coat consisting of 80 per cent cement mortar and 20 per cent lime mortar, with a dash coat of 1½ parts of crushed stone screenings and one part of cement.

The finish floors are of quarter sawed yellow pine, oak stained, with the exception of the bedrooms, which have a flat grain, while maple floors are provided in the kitchen, pantry and bathroom. The contractor had particularly good success in staining yellow pine trim to imitate oak, and the products used in this operation are made by the Pitcairn Varnish Co., of Milwaukee, Wis. All interior floors and trim were stained and shellaced one coat each and given a final coat of varnish. All doors are of yellow pine, two-panel stock design.

The bathroom contains one "Trapera" closet with high tank, one 5-ft. "Nioba" bathtub, and one 18 x 21-in. lavatory, complete with two faucets. In the

Basement Plan—Scale 1/16 In. to the Foot

Section Through Main Wall of the House

Floor Plan—Scale 1/16 In. to the Foot

sills, giving additional bracing to the construction. The ceiling joists are 2 x 3 in., extended to form part of the cornice, while the rafters are 2 x 4 in. placed 16 in. on centers. After the roof had been framed one layer of building paper was applied, the final covering consisting of asphalt shingles, exposed 4 in. to the weather. The shingles are of a type made by the Beckman-Dawson Co., 19 South La Salle Street, Chicago, Ill.

The chimney is built of square cement blocks, of special design made by The Multiplex Concrete Machinery Co., Elmore, Ohio. Bishopric board, made by the Mastic Wall Board & Roofing Co., Cincinnati, Ohio, is nailed direct to the studding. On account of the elimination of sheathing it was deemed advisable to place a 6d. cement-coated box nail in every lath to form a strong bracing and stiffening, and the joints in this work were broken every 3 ft. and properly rabbetted behind the frame.

Interior plastering consists of one coat of wood

kitchen is a 20 x 30-in. two-piece enameled iron sink, with long back and drainboard and three faucets. In the attic is a galvanized iron tank having capacity for 5 bbls., to which water is pumped from the cistern through the medium of a New Alert hand pump. Rain water is discharged from the roof to the cistern through the downspouts and then pumped to the attic tank, from which point connections are made to the fixtures in the kitchen and bathroom. The plumber connected a 30-gal. hot-water tank to the coil in the furnace, while arrangements for gas supply to the hot-water equipment were also made. The plumbing fixtures throughout are of types made by the L. Wolff Manufacturing Company, Chicago, Ill.

The heating equipment consists of a No. 45 "Leader" warm-air "pipeless" furnace, made by the Hess Warming and Ventilating Co., 1201 Tacoma Building, Chicago, Ill. The furnace is of all-steel construction, made with welded joints, which pre-

vents the escape of smoke and gases; has a rated capacity of from 12,000 to 16,000 cu. ft., and connects with a combination register face opening measuring 24 x 36 in.

As shown on the basement plan, the furnace is set slightly off the center of the basement to supply an abundance of warm air through the register, which is placed at a point between the living and dining rooms. The furnace is set directly beneath

from the register. The introduction of a large volume of warm air naturally displaces the colder air, which, being heavier, descends to the floor and is being constantly drawn back into the furnace through the two return air inlets in the register, insuring a rapid and constant circulation of air.

It is well to point out that the "pipeless" furnace is not a solution of all heating problems, as it has its limitations, but is recommended by the manufacturer as especially adapted to buildings where a number of smaller rooms open into one or two main living rooms.

One of the strongest points urged in favor of the "pipeless" furnace is its economical fuel consumption. The installation of a "pipeless" furnace is extremely simple and the amount of cutting in the floor is confined to one opening as no stacks are re-

Rear View of House Showing Window Exposure

the register, which is divided into three sections; a central heat outlet, with cold-air return inlets on either side. All of the heat from the furnace is discharged upward through the central part of the register, and the two end openings are connected with outer spaces on the sides of the furnace. The inner casing, forming one side of the return air passageways, terminates about 8 in. from the basement floor, so that the air will circulate beneath it, and the space beneath the outer and inner casings is about 6 in.

When the heated air leaves the register it rises to the ceiling and diffuses through all the rooms which are open to the main room in which the register is

Cistern in the Northeast Corner of the Basement

installed. It will be seen, therefore, from the accompanying first floor plan that all interior doors must be left open in order that the warm air may circulate throughout the house and penetrate the bedrooms, bathroom and kitchen, which are farthest

Front View of the Heater Showing Hot Water Boiler

quired. The equipment is installed without horizontal pipes, which means that no heat is lost by radiation and waste heat in the basement is reduced to a minimum because of the insulation afforded by the cold air chambers on either side of the furnace.

An examination of the front view illustration of the furnace shows a large water pan over the feed door, to provide a proper percentage of moisture.

The contractor and builder for the cottage here shown was J. C. Lawrence, 15322 Center Avenue, Harvey, Ill., who also prepared the plans and supervised the construction. Through his courtesy we are able to present a few figures of cost showing the total to be \$2,021.80.

Estimate of Cost

Excavating and grading.....	\$25.00
Foundations	200.00
Lumber and trim	507.80
Carpenter work	300.00
Plumbing	262.00
Electric lighting and fixtures.....	50.00
Furnace heating	80.00
Hardware	25.00
Lathing, plastering, stucco and wall board.....	422.00
Sheet metal work.....	20.00
Painting	70.00
Roofing	60.00
	<hr/> \$2,021.80

The building was completed in August of the present year and is an excellent example of a resi-

Rear View of Pipeless Furnace Showing Smoke Pipe

dence that can be erected in any part of the country to accommodate a small family and for a sum well within the limits of a moderate income.

USE OF BRICKS IN NEW YORK

Greater New York is the leading common-brick market in the United States, about a billion brick being used there annually. The principal source of this supply is, according to the United States Geological Survey, the Hudson River region, extending on both sides of the Hudson from New York to Cohoes, including Bergen County, N. J., and within the last few years the Raritan River district, Middlesex County, N. J., has sent large quantities of common brick to New York.

In 1915 the output of common brick in this region was 960,527,000 brick, valued at \$5,009,065, or \$5.21 per thousand. This was an increase of 72,261,000 brick and \$658,233 and of 31 cents per thousand over 1914.

The New York portion of this region marketed 741,568,000 common brick in 1915, valued at \$3,744,548, or \$5.05 per thousand, which was about three-fourths of the quantity and value of the entire region and was an increase of 62,448,000 brick and \$461,149 and of 22 cents per thousand over 1914. Ulster County was the leading county in production and value of common brick, reporting 229,343,000 brick, valued at \$1,110,492, or nearly a third of the output and value of the New York portion of the region, an increase of 42,962,000 brick and \$214,186 over 1914. Dutchess County was second and Rockland County third.

New Jersey's portion of the production of the region was 218,959,000 brick, valued at \$1,264,517, an increase of 9,813,000 brick and of \$197,084 compared with 1914. The average price per thousand increased 68 cents compared with 1914.

AN UNUSUAL STORE DESIGN

An unusual store design has been drawn by Architect Frank M. Tyler for a building to be erected on Olive Street, near Eighth, Los Angeles, Cal., which will have a frontage of 60 ft. and a depth of 150 ft. The street floor will be occupied by three stores, with the usual plate-glass fronts; while the second floor is designed on lines of the Tudor period, with a facing of white stone and red ruffled brick, and slate roof. The general construction of side and rear walls will be of brick.

COST OF BUILDING OPERATIONS IN 1915

Building operations in many of the larger cities of the country increased in 1915 according to the United States Geological Survey, Department of the Interior. In 48 selected cities the total cost of building operations was \$641,769,199, an increase of \$22,016,845, or nearly 4 per cent over 1914. Twenty-eight of these cities showed increase and 20 showed decrease.

New York was the leading city in cost of building operations, with \$103,023,800, an increase of \$28,993,559 over 1914. Chicago, which was the leading city in 1914, was second in 1915, with building operations costing \$97,291,400, an increase of \$14,029,690. Brooklyn was third, with a total of \$45,601,851, an increase of \$3,729,544 over 1914.

The number of permits issued or buildings erected in 1915 in these 48 cities was 201,190, a decrease of 2,542 compared with 1914. The number of permits or buildings ranged from 469 in St. Joseph, Mo., to 14,515 in Brooklyn, N. Y. The average cost per operation was \$3,190 in 1915 compared with \$3,042 in 1914.

One million dollars' worth of Carthage stone and polished marble, it is said, will be used in the \$15,000,000 Hotel Commonwealth, planned to be erected in the Times Square district of New York City.

BRIEF REVIEW OF THE BUILDING SITUATION

BUILDING OPERATIONS FOR AUGUST IN 123 CITIES SHOW
ONE PER CENT DECREASE COMPARED WITH AUGUST, 1915

THE reports which come to hand from all sections of the country indicate that building operations are being conducted upon practically the same scale of activity as prevailed a year ago at this time. It is true, some sections indicate a striking increase in activity while others report a shrinkage in the planning of new construction work so that one just about offsets the other. The figures for August presented herewith covering 123 cities of the country indicate a loss of 1.1 per cent, as compared with August, 1915. In considering the four zones into which we have divided the country for the sake of comparison, the Eastern section shows a falling off of 11.2 per cent as compared with last year, there being 49 cities reporting, of which 26 show increases and 23 decreases.

CITIES IN EASTERN STATES

	August, 1916	August, 1915

Yonkers	242,600	323,300

From the central portion of the country we have reports covering 37 cities, of which 25 show increases and 12 decreases, with a resultant gain of 4.74 per cent, as compared with August last year. The striking feature is the heavy falling off in projected buildings in Chicago, Cincinnati and Milwaukee, while notable increases are found in Akron, Cleveland, Detroit, Indianapolis, Kansas City, Minneapolis, St. Louis and Toledo.

CITIES IN MIDDLE STATES

	August, 1916	August, 1915
Akron	\$2,400,000	\$499,010

Toledo	1,348,197	747,083
Topeka	152,018	66,719
Youngstown	293,500	154,815

The greatest increase in building operations is found in the Southern tier of states from which 19 cities make reports indicating a gain of practically 31 per cent over August, 1915. This is due largely to the greater volume of permits issued in Baltimore, Birmingham, Dallas, Fort Worth, Jacksonville, Oklahoma City, Richmond and Washington.

CITIES IN SOUTHERN STATES

	August, 1916	August, 1915
Atlanta	\$323,690	\$372,175

Wilmington	188,411	154,368

Coming now to the extreme Western section of the country and including the territory lying west of Denver, we have 18 cities reporting a gain of 12.29 per cent, as compared with August last year. The notable increases are found in Denver, Pasadena, Sacramento, Salt Lake City, Seattle, Spokane and Tacoma. Decreased activity is reported from Oakland, Portland and Stockton.

CITIES IN EXTREME WESTERN STATES

	August, 1916	August, 1915

CURRENT NEWS OF BUILDERS' EXCHANGES

NEW OFFICERS, OUTINGS, MEMBERSHIP CAMPAIGN, ATHLETICS AND OTHER ITEMS OF INTEREST

Model Home Contest of the Detroit Builders' and Traders' Exchange

THE interest shown by members of the Builders' and Traders' Exchange of Detroit, Mich., in the steps which are being taken to secure an ordinance to provide for better housing conditions for the workmen of the city is such as to cause the contemplation of a contest for model houses of a type calculated to meet the requirements of that class of workers. It has been suggested that a prize of a silver loving cup be awarded to the member who submits the best plan for a house costing from \$1,200 to \$1,500.

The members of the Exchange are enthusiastic supporters of the baseball team known as the "Detroit Tigers." As a token of appreciation of their loyalty, Frank Navin, owner of the Tigers, invited the Exchange to be his guests at the game played with St. Louis on Sept. 7. Over 500 members accepted and formed themselves into a motor car parade, which, headed by a band, formed a triumphal entry into the ball park.

The Exchange reports the addition of a number of new members and several new exhibits have been added to the Permanent Building Exposition.

The Los Angeles Builders' Exchange

At a meeting of the Los Angeles Builders' Exchange, held on Aug. 11, the Special Committee appointed a month before to map out plans to be followed by the organization asked for more time, owing to the complication of its problems. Our correspondent, writing under date of Sept. 5, says in regard to the matter: The committee has found Los Angeles people to be unlike those of many other communities, in disposition to disregard conventional methods, and especially in tendency to eliminate the architect in building. In this connection Secretary Walter Risk remarked that within recent years "hundreds of poorly informed people have suffered disaster by placing themselves in the hands of irresponsible so-called architects, who promised to 'take care of everything.'"

New standing committees on Finance, Publicity, Law and Rules, Employment, Educational, Floor and Membership were appointed. The Exchange has recently received a number of new members.

The Quad-City Builders' Exchange

Members of the Quad-City Builders' Exchange, which comprises the cities of Moline, East Moline, Rock Island, Ill., and Davenport, Iowa, enjoyed their first annual river outing on Saturday, Aug. 12. More than 300 participated in the trip up the river to Smith's Island, where a program of athletic events was given. The voyage was made on the steamer Marquette and barge, the boat leaving the tri-cities at 2.15 o'clock in the afternoon and returning after 9 o'clock.

A band furnished music during the day, while other entertainment was furnished on the boat. Besides the local contractors were delegations from Clinton and Burlington, Iowa. C. P. Massard, secretary of the Iowa Builders' Association, was in attendance, as well as many master plumbers.

With a view to improving conditions in connection with the awarding of contracts the Exchange recently appointed a committee for the purpose of drafting a

Code of Practice for bidding on contract work. As a result of the efforts of this committee, it was decided that beginning Sept. 1 the members use, when competing, the Nelson Form of Choosing Bidders and Awarding Contracts, of which Herman W. Nelson of Moline, Ill., is the author. The committee also decided the factors which shall be used by the various branches of the building industry in asking pay for competitive bids. The Exchange has furnished to members a sign to hang in their offices to notify the public that hereafter they will ask pay for figuring in competition.

In order to make plain what the member is expected to do, we present the following paragraphs from the recommendations of the committee:

If a customer asks you to figure a job, you will hand him one of the "bidders' agreements" and tell him that you will estimate his work on that basis only.

If he wants to give you the job, without asking other bidders for figures, then it doesn't make any difference to him whether you charge him for figuring or whether you include the charge in your figure on the work.

He must pay for this work anyway, and always does, directly or indirectly.

If he or his architect wants your figure to compare in competition with other bids and then "reserve the right to accept or reject any or all bids," then they should pay you for your work.

New Secretary of Dayton Builders' Exchange

The many friends of Thomas P. Kearns, former State Inspector of Workshops and Factories, will be interested in learning that he has been appointed secretary of the Builders' Exchange of Dayton, Ohio, succeeding Michael Redelle, who has become welfare director for the Dayton Engineering Laboratories Company.

Johnstown Builders Contemplate an Exchange

The contractors of Johnstown, Pa., are busily discussing the advisability of organizing a Builders' Exchange. The project was first broached last fall, but opposition developed which it is now hoped will be removed. It is expected that the Master Builders' Association will take up the matter in the near future and the younger element is especially anxious to see the project succeed.

New Officers of the Regina Builders' Exchange

At the recent annual meeting of the Builders' Exchange of Regina, District of Saskatchewan, Canada, the following officers were elected:

President.....W. M. Wilson
Vice-President.....D. D. Smith
Secretary.....M. L. Moyer
Treasurer.....A. Young

The executive committee is composed of W. R. Harris, R. J. Lecky, D. J. McKay, W. R. Talbot, W. Whiteford, J. M. Adam, W. J. Hastings, J. M. Taylor and T. A. Wilson.

Reorganization of Montgomery Builders' Exchange

It has been decided to reorganize the Builders' Exchange of Montgomery, Ala., and to so enlarge its sphere of usefulness as to practically make it a new organization. This was decided on at a meeting held on Aug. 25, some forty of those prominently engaged in the building business being in attendance.

No. 77
**Flexible Storm-
Proof Door Hanger**

**Storm Proof
Rail**

Open Your Door to Better Building

If you want your work to be characterized by a higher grade of construction, you should hang warehouse and barn doors with nothing but the Flexible Storm-Proof Door Hanger, our model No. 77.

Made from heavy-gauge steel with great carrying capacity, it is perfect running and its flexible hinge-joint allows the door to swing out if bumped, while hanging free from vibration ordinarily.

With this hanger should be used our Storm Proof Rail, fitting close to the building, bird-proof, requiring no brackets and fully protecting the space between the door and rail-bottom.

Catalog upon application.

A Big Advertising Campaign That Helps YOU!

During the second week in October thousands of Roofers, Contractors, Carpenters and Dealers all over the country will have an especially effective help in getting *more business*. October 9th to 14th is to be *Re-Roofing Week*, when all of our Asphalt Shingle advertising will be concentrated on urging house owners to replace their leaky roofs with a new, long life *Asphalt Shingle* roofing.

National Re-roofing Week—October 9 to 14
Re-roof Your Home With Asphalt Shingles

This is the time when most people are ready to put their roofs in shape for the winter—the time when you can get a splendid lot of business—*if you go after it*. This campaign will make it easier for you—will help you get twice as much business for the same effort.

October 9th is also National Fire Prevention Day. The newspapers and magazines will contain many articles urging the use of fireproof building materials. All this will help, because *Asphalt Shingles* make the fire-resistant roofing that is recommended by so many Fire Chiefs and Building Commissioners. Sparks and burning embers are harmless upon them. So here is an additional argument that will be very effective in gaining you many an order at this time when people are also thinking of fire protection.

Prepare now to push your *Asphalt Shingle* business during *Re-Roofing Week*. Make sure that you have a plentiful supply on hand to take care of the business that will be created. Tell your customers the advantages of *Asphalt Shingles* and connect up with the powerful effect of our national advertising during *Re-Roofing Week*.

If you mail a letter to several house owners whose roofs need attention, or call upon them, or call them up on the telephone, you will probably find them ready to tell you to go ahead with a new, leakless *Asphalt Shingle* roof. Our advertising will make the sale ready for you to close.

ASPHALT SHINGLE PUBLICITY BUREAU, 954 Marquette Bldg., Chicago

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

The Garage Door Problem

Just at the present time there seems to be considerable discussion as to the proper method of opening heavy garage doors and arguments have been presented pro and con as to the best way in which this can be satisfactorily accomplished. With more than two million pleasure automobiles in daily use in the United States, any problem connected with garage construction should prove of more than passing interest to builders, carpenters and contractors. The first garages were built with their doors swung on hinges, but the hinges on the market at that time were rather roughly finished. An old-fashioned strap or T-hinge, strong enough to swing a heavy garage door, did not add much to the general appearance of the building and, moreover, at that date there was nothing on the market to prevent the door slamming on a machine coming in or going out of the garage. In order to fully meet the requirements of the case, improvements were made from time to time, with the result that now there are hinges designed especially for garage use.

holder consisting of an arm of steel which holds the doors open against the strongest wind. This holder automatically locks the door open and it is released by a pull on a chain. In Fig. 1 of the illustrations is presented a picture showing a pair of garage doors open and closed—one showing the arrangement of the holder, while the other gives an idea of the appearance of the

Fig. 2—Detail of the Door Holder

The Garage Door Problem—Fig. 1—Showing Door Holder Applied and Appearance of Door Hardware in Position

These hinges are made heavy and strong, yet neat in outline and carefully finished. In fact, the hinges are of such a nature as to add materially to the architectural appearance of the garage in connection with which they are used. These hinges are equipped with ball-bearing washers, so that the door in opening does not grind together the wearing surfaces of its hinges, but, on the contrary, literally glide over ball-bearings like the wheels of an automobile. Doors hung on hinges of this nature close snugly; in fact, just as weathertight as the front door of a dwelling. Swinging doors may be safely and easily locked, for the point is made that it is easier to swing garage doors open than to push them back. There is nothing about the door hinge to adjust or get out of order and any carpenter or builder who can hang a house door can produce a good looking, easy working job. In order to prevent the doors from slamming, the Stanley Works, New Britain, Conn., recently placed upon the market a garage door

door hardware when applied. In Fig. 2 the holder is shown more in detail.

Asphalt Shingle Re-roofing Week

A double significance will be attached to Monday, Oct. 9, when "National Fire Prevention Day" will be celebrated throughout the country. The occasion will also mark the opening of Re-Roofing Week, an advertising campaign that will be launched by the Asphalt Shingle Publicity Bureau, Old Colony Building, Chicago, Ill., to arouse enthusiasm regarding the value of asphalt shingles—"The Roof that Stays Young." Extensive preparations have been made by the bureau to attract widespread attention on the part of homeowners to one particular feature, that of re-roofing, an opportunity that can be followed up to profitable advantage by progressive contractors and builders. The Bureau

intends to run striking advertisements in several national weekly magazines and will also co-operate with manufacturers and dealers in an endeavor to stimulate enthusiasm and arouse interest on behalf of asphalt shingles.

National Fire Prevention Day always has official recognition. It is common practice for state fire marshals to enlist the co-operation of mayors of cities, superintendents of schools, chambers of commerce, associations, clubs, as well as individuals, in urging the public to make every day an occasion for fire prevention. The daily newspapers direct attention to the annual losses that are brought about through the use of inflammable building materials and emphasis is laid on the desirability of using fireproof and fire-resisting building materials.

Here is an opportunity for enterprising contractors and builders to increase their business by taking advantage of such publicity. The early part of October is the time when most people are thinking of repairing their roofs to withstand the siege of the coming winter. The advertising campaign of the Asphalt Shingle Publicity Bureau will make people think seriously of having a roof that can be covered on a repairless basis, and one that will have a lasting appearance. It is wise economy to put repair costs into an investment that will head off future repair bills.

The contractor and builder who is alive to the re-roofing possibilities in his home town and surrounding territory will call to mind numerous prospects that can be influenced at this time. He may ask himself as to the best methods to pursue in getting a large share of the business that will be developed in his territory through this advertising campaign. In the first place, it is desirable to make a list of prospects. A circular letter should then be prepared and mailed promptly, so that the advertising may be made doubly effective. Literature on asphalt shingles should also be sent, all of which should be followed up by personal or telephone calls or further letters. Personal calls make a greater impression on the prospect and bring better results than indirect methods.

Newspapers can be used effectively, for people are always on the alert for news. Call up a reporter and tell him the importance of "National Fire Prevention Day" and be sure and have him quote you on the subject. Then include your talk on Re-Roofing Week and emphasize the importance of asphalt shingles as a fire preventive roofing material. Advertising is sure to attract attention if run in the same issue, and some forceful statements about asphalt shingles run every day during Re-Roofing Week will be profitable. Local interest will be stimulated, and the foundation for future business will be laid in addition to immediate orders that will result from such aggressiveness.

Display cards tacked to buildings under construction will attract the right kind of attention, while similar cards nailed to trucks or wagons will be seen by people all over town. It is simply a question of individual persistency—aggressiveness and enthusiasm backed up by an intelligent knowledge of the merits of asphalt shingles. Contractors and builders will find manufacturers and dealers ready to co-operate in this movement and will be glad to furnish electrotypes, display cards and literature. The time is short, however, and calls for prompt action.

New Myers Faultless Door Hanger

Among the latest candidates for popular favor in the way of a door hanger, is the construction illustrated herewith and which has just been placed upon the market by F. E. Myers & Brother, Ashland, Ohio. It is known as Myers Faultless Adjustable Tandem Door Hanger and Self-Cleaning Track. It is referred to as being simple, rigid and efficient in construction and thoroughly protects the top of the door from the elements. The arrangement is such that lateral adjustment to and from the building is readily made as well as vertical adjustment for the purpose of raising or lowering the door. The wheels or rollers are turned from steel shafting and revolve on hard steel roller bearings. The engine track shown in Fig. 3 is pivoted in the center, al-

lowing it to oscillate and adjust itself to any variation in the track. The lateral adjustment shown in Fig. 4 consists of a heavy screw bolt with a screw head adjusted by means of an ordinary screwdriver. The object of this adjustment is to permit the use of different thicknesses of doors and also to close up all cracks between the door and building. The vertical adjustment

Fig. 3—The Engine Truck

Fig. 4—Showing the Lateral Adjustment

is a heavy iron bolt passing through a part of the hasp. The flexible joint with which the hanger is fitted permits the door to adjust itself to uneven surfaces on the building and also allows it to swing out at the bottom when desired. In Fig. 5 is shown the self-cleaning track, the special feature of which is the continuous opening between the track and the building. The covering or roof of the track is attached to the building at the upper edge by means of lag screws or spikes and extends downward and outward to a point below the top of the door, thus covering it completely and protecting it from the weather. An idea of the construction may be gathered from an inspection of Fig. 4. The track proper is a flat, hard steel bar attached to the cover by means of steel stud rivets, leaving an opening between

Fig. 5—The Myers Self-Cleaning Track

the track and cover through which any dust or dirt will naturally fall, thus insuring a clean runway for the trolley at all times and under all conditions. The track is provided with an end stop made of wrought steel, which closes the end of the track and is held in position by a rivet in the track and a lag screw passing through the center of the track cover and the end stop. This not only stops the door but stiffens the track.

A Federal motor truck recently lent valuable aid in emergency transportation in Nevada, for a forest fire had completely destroyed the town of Verdi and it was necessary to transport troops from Reno as quickly as possible. The truck held thirty-nine men and covered the eleven miles between the two towns in fifty-five minutes. The relief party assisted the sufferers and the truck was used to transport household goods to places of safety and to haul provisions from Reno. The truck was owned by the Verdi Lumber Co. and

"Neponset" is my middle name, and this shingle is my card. And let me tell you, it's *some* drawing card, too.

My Neponset "card" draws two distinct classes of people into my store; those who can afford shingles of the finest slate, but prefer Neponset Twin Shingles because they have the beauty of slate, they wear like slate and cost much less; and those who know that Neponset Twin Shingles are not only beautiful to look at but give one hundred cents' worth of dependable service for every dollar invested.

So you see my business on

NEPONSET

TWIN

SHINGLES

is brisk. I have an argument "that holds water" that I successfully use on the man who owns a "seven passenger eight" and the fellow who doesn't.

In other words I can convince any man that Neponset Twin Shingles are unquestionably the best shingle value on the market today. The people in my town come to me with their roofing problems and I solve them with Neponset Twin Shingles. That's why I am successful.

If you try, perhaps you can become the Neponset Man in your town.

Send the coupon today for information about the shingle that looks like slate, and possesses many of the advantages of slate, yet which costs no more when laid than good wood shingles. Address

A Practical Exhibit of Willis Ventilators

It is an obvious fact that the only way to secure satisfactory ventilation of a building is to install a proper ventilating system and this applies to structures for whatever purpose they may be used. In Fig. 6 of the illustrations we show a general view of a barn which is equipped with five of the well-known Willis ventilators made by the Willis Manufacturing Company, Galesburg, Ill. The barn is 200 ft. long and 50 ft. wide, and has a 50-ft. wing extending from the main building. The five ventilators shown are of the Louvre style and are said to keep the structure constantly supplied with fresh air. These ventilators are made in various styles and sizes, thus adapting them to meet varying requirements and for any pitch of roof. They are arranged to be ornamented with special styles of weathervanes, thus rendering them orna-

Fig. 6—Practical Exhibit of Willis Barn Ventilators

mental as well as practical. The principle on which the ventilator is constructed is said to be such that the draft is always in the right direction no matter how hard the wind may be blowing. We understand that the company always carries a large stock of these ventilators so as to insure prompt shipments at all times. A general catalog, known as No. 7, has been issued by the company and this illustrates the complete line of Willis products, which embrace practically everything in the line of sheet metal building materials.

Catalog of Chicago Grille Works

We have just received from the Chicago Grille Works, 836 Wells Street, Chicago, Ill., a copy of Catalog No. 21, containing many new and attractive designs in grilles, parlor columns, colonnade openings, consols and sideboards, each of which is described in a way to eliminate any misunderstanding in ordering goods from the catalog. It is stated that all products are made from strictly kiln-dried lumber and should be filled or varnished immediately on receipt of shipment in order to prevent the wood from swelling. The catalog has 48 pages, the first portion of which is devoted to an extensive line of grilles. Next in order are bookcases, colonnades, consols and sideboards, a number of full-page illustrations giving the reader an excellent conception of the construction and finished appearance. Among other interesting features is a very attractive combination desk and bookcase, the left side housing the bookcase and the right side a desk, with drawers underneath. This combination measures 46 in. high, 42 in. long and columns 10 to 8 in. Electric light posts for interior use are also featured, while on the last two pages are cuts of columns, corner brackets and capitals. Prices are quoted for plain red oak, unselected birch, yellow pine and cypress, not varnished, and the statement is made that quotations for other woods will be sent on application. The catalog should be of value to contractors and builders who are called upon to suggest ideas for interior treatment of houses, bungalows, etc., and a copy may be had free by writing to the address above given.

BUILDING MATERIAL CATALOG

Sterlings' vs. "Just Wheelbarrows"

Tim Says:—

"I was on earth a considerable number of years before I caught on to the big difference in wheelbarrows.

"Jest naturally thought a wheelbarrow was a wheelbarrow, and the word meant a 'Rotten Bunch of Something,' that got the shakes and quit about every so often, and started a cussin' match between the boss and the fellow who did the wheelin'.

"Most people is the same as I was, and has an idea that a wheelbarrow is jest a box, with a couple of sticks, and a wheel hitched onter it.

"But let me tell you there's a *heap* o' difference, and if you want to know, jest ask for 'Sterlings,' instead of wheelbarrows, and you will discover that a Sterling is mor'n a common old perambulator, bein' as it is a dern good piece of wheelin' machinery, built to last and stand the hard knocks.

"Why that Sterling even has self oilin' bushin's in the wheels; clamps that keep the handles from breakin'; riveted legs, and a lot of more good things that puts them in a class by themselves.

"And speakin' of 'class,' there's a lot of class to Sterling Wheelbarrows—they look good all over—and they are.

"Wheelbarrows is wheelbarrows al-righty, but Sterlings is different."

—TIM TRUNDLE.

many parts of the country, and contractors and builders will therefore find much to interest them in a booklet entitled "Apollo Best Bloom and Apollo-Keystone Copper Steel Galvanized Sheets," which has just been issued by the American Sheet & Tin Plate Co., Frick Building, Pittsburgh, Pa. This booklet is profusely illustrated with half-tone engravings of examples showing the durability of the company's product. There are also tables of weights of Apollo Best Bloom galvanized flat sheets and of Apollo galvanized formed products, etc., the latter giving weights per bundle and per square. Apollo-Keystone copper steel galvanized sheets are said to possess an added degree of durability through the use of an alloy known as "Keystone Copper Steel." The rust-resisting properties of this alloy are said to have been thoroughly established by

Fig. 7—A Silo Built of "Apollo" Galvanized Sheets

actual service and exposure tests extending over a number of years. Keystone copper steel is therefore used as the base of Apollo-Keystone galvanized, which the company recommends for roofing, siding, tanks, etc. An example of its application in silo construction is shown in Fig. 7.

Ambler Asbestos Shingles

There has just been issued from the press by the Keasbey & Mattison Company, Ambler, Pa., a handsome brochure, attractively printed on a good quality of paper, profusely illustrated with well executed halftone engravings and bearing the title, "The Glory That Once Was Paris." In this case the Paris referred to is located in Texas, a thriving city of about 15,000 people, where late in the afternoon of March 21 and before noon of March 22 more than two-thirds of the town, including all of the business portion, had been destroyed by fire. The conflagration covered thirty blocks, and in addition to the business section included about 2000 homes. By a strange coincidence, Augusta, Ga., was visited by a destructive fire during the same twenty-four hours that Paris was ablaze. Here, ten business and twenty residential blocks had been swept by the flames, with a loss in the two cases running into the millions. Some of the halftone pictures show scenes after the conflagration. The lesson to be learned is that the substitution of more enduring and noncombustible material would have prevented the spread of the fires. It is especially pointed out that if asbestos shingles had been used upon the roofs of the houses, the flames would not have made such headway, as there is nothing about these shingles to burn or carry fire. The point is made by the Keasbey & Mattison Company that a shingle made from asbestos fiber and cement becomes tougher, stronger, and more resistant to both fire and weather the longer it is exposed. In addition to the fire scenes

(Continued on page 74)

Hydrated Lime Plaster Makes Quiet Homes

For
Scratch and
Brown Coats

It's the great sound deadener. Will put quiet in the home. Will make a big difference in every house where you use it.

Hydrated Lime Plaster is the ideal plaster for interior walls.

FOR THESE REASONS:

SOUND—The hardened walls contain millions of tiny dead air cells. These absorb sound and reduce reflection and transmission to a minimum. Keeps the noise from being transmitted through the walls from one part of the house to another.

STRAIGHTER WALLS — Hydrated Lime Plaster is a slower setting plaster and in drying gives the plasterers time to finish the walls to true and even surfaces and angles. This slower set also permits the plasterer to eliminate lath cracks.

ECONOMIES—Hydrated Lime has a high sand carrying capacity. (Be sure to get our complete specifications, giving proportions of hydrated lime and sand.) There is no waste of material through droppings. These can all be retempered and used either the same day or the day after.

Hydrated Lime Plaster costs no more than other plaster. Try it on the buildings you are now constructing. It's the perfect plaster for home construction.

Our Bulletin "G" is valuable to wide-awake builders. Send for your copy of "Plaster Facts."

Book on Plumbing and Heating Materials

An exceptionally valuable work covering plumbing and heating materials and the methods employed in installing them efficiently has been published by the Hardin-Lavin Co., 4538-48 Cottage Grove Avenue, Chicago, Ill., and distributed broadcast throughout the country among contractors and builders. The book contains over 200 pages, and it is profusely illustrated. The company recommends the book as answering the ever-increasing demand for high-grade plumbing and heating supplies at the right prices. It stands ready to supply anything from a fitting to a complete plumbing or heating outfit, and guarantees new and attractive designs of lasting durability, prompt and direct shipments and easy instructions relative to installation. The catalog contains a wide variety of bathroom combinations and accessories, laundry trays, kitchen sinks, lighting fixtures, etc., while the numerous plans, elevations and detail drawings that are presented are sufficient to warrant a place for this volume in the files of the progressive builder.

The "Van Guilder" Building System

Under the above title there has just been issued by the Van Guilder Hollow Wall Co., 712 Chamber of Commerce Building, Rochester, N. Y., an attractive folder of liberal proportions, illustrated by numerous half-tone engravings, and relating to the "Van Guilder" concrete double-wall system of building construction. The point is made that the buildings erected by means

of this system are like thermos bottles—a house within a house. In connection with the matter, of special interest to the builder, as well as to the prospective owner, is a table of comparative costs gathered from the use of the double-wall system during the past six years:

Van Guilder double 4-in. walls	10c to 14c per square or surface foot
Frame walls	16c per square or surface foot
Tile walls	19c to 24c per square or surface foot
Tile walls	10c to 24c per square or surface foot
Cement blocks	23c to 25c per square or surface foot

To these figures of cost must be added a fair profit for the contractor. The company states that many appear to have a wrong impression of its business. It does not simply make and furnish machines and equipment for doing the work, but the company maintains a Bureau of Information and Service for the purpose of spreading knowledge and directing the builder how to proceed correctly and economically. The company gathers from hundreds of builders facts and experiences, a single item of which is often of great value to the man doing the work.

Many of the illustrations in the folder relate to buildings which have been erected by the "Van Guilder" system, these embracing barns, dwellings, schoolhouses, etc., etc. Several pages are devoted to the new "Van Guilder" 1916 flexible sliding side plate and angle iron corner system, the illustrations showing the machine and its parts, as well as the work which may be accomplished by their use. They also show a few of the intricate wall-building problems which are constantly arising. Not the least interesting feature of this more than usually interesting folder are the machines for building double-wall silos and those for use in erecting triple walls with two air spaces for concrete cold storage structures and ice houses. Reference is made to the important farm buildings which have been put up by the "Van Guilder" system and to the great satisfaction which it has given wherever introduced.

HYDE-MURPHY COMPANY, Ridgway, Pa.

New York Office, Pittsburgh Office,
10 East 43d St. Liberty Bank Bldg.

FIREPLACE MATERIAL

A New Style Damper

This fireplace damper is made in both flat and dome styles. The lever sets under the first row of brick, unexposed, but very accessible and easily operated.

Also made with lower lever so a steel angle can be placed under edge of damper. We make several other style dampers.

Catalog 1590 shows these Dampers in detail and gives valuable suggestions as to the best construction for fireplaces.

Other Goods We Make

Cleanout Doors, Ash Trap Doors, Cast Chimney Thimbles, Brass Thresholds, Andirons, Fire Baskets, Fire Sets, Fire Screens, Spark Guards, Gas Logs, Door Knockers, Sink Brackets, Screen Door Hinges, Double Acting Hinges, Cast Iron Sash Pulleys, Furnace Pulleys, Stove Pipe Registers, Dampers, Damper Clips, Saw Vises, Door Latches, Foot Scrapers, Chest Handles, Flush Rings, Harness Hooks, House Numbers, Door Pulls, Samson Wind Mills, Feed Mills, Alfalfa and Ensilage Cutters, Gasoline Engines.

Asphalt Shingles for Railroad Stations

As a result of many years' practical buying experience, railroad companies purchase their goods solely on an efficiency basis. They want long life building materials that give the maximum services for their cost. According to the Asphalt Shingle Publicity Bureau, Old Colony Building, Chicago, Ill., railroads are extensive users of asphalt shingles for the foregoing reasons. The depot at Wequetonsing, Wis., Fig. 8, is covered with asphalt shingles, and no matter how thick the burning sparks may fall on the roof, the asphalt shingles protect the structure. Another important point is that their light weight dispenses with the use of heavy joists or rafters, which would be essential if a heavy

Fig. 8—Asphalt Shingles for Railroad Stations

roof covering was used. The surfacing of crushed rock products, in natural colors, is claimed to shield the shingles against the wearing effects of time and weather, and the colors are said to never fade.

The Stanley Scrap Book of Garage Hardware

One of the latest schemes in promoting the sale of a manufacturer's product is that which has been adopted by the Stanley Works, New Britain, Conn., and which consists in the distribution to the hardware trade of a handsome scrap book entitled "What We Are Doing to Help You Sell More Stanley Garage Hardware." This book in size measures 10 x 14 in. and the frontispiece shows the publications used in the promotion of the Stanley garage hardware advertising campaign. There are illustrations of mounted samples of Stanley garage door holder No. 1774, one being for counter use and the other for the use of traveling salesmen. After this come descriptions of the new Stanley garage hardware catalog for jobbers and hardware dealers, also a special catalog for architects, which is now in preparation. A sample of the covers of this new catalog is pasted on the page facing the description. On the two following pages the signs, display cards, etc., furnished to dealers are illustrated and described, together with the various folders for distribution by hardware dealers. Several pages are given up to information about the various publications used by the company and including, of course, THE BUILDING AGE. There are also a number of pages to which are pasted sample advertisements showing the type of material that is appearing in various trade and class publications.

Further Information Regarding Flex-A-Tile Roll Shingles

Supplementing our reference a short time ago to the new Flex-A-Tile Roll Shingle which has just been placed upon the market by the Heppes Company, 1011 Kilbourne Avenue, Chicago, Ill., it is interesting to state that it is really a regular full size 32-in. wide roll of individual asphalt shingles which when placed give all the attractive appearance of a high-grade asphalt shingle roof combined with the economy of roll roofing, inasmuch as the asphalt shingle effect is said to be obtained with no greater labor cost than with roll roofing. This is something in which the builder and roofing contractor are likely to be interested by reason of the fact that it is well calculated to appeal to the prospective client. Samples of the new Flex-A-Tile

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

Modern Lighting Fixtures

In view of the attention which is being given at the present time to modern lighting fixtures for residences and other buildings, unusual interest attaches to the handsome catalog of 184 pages, relating to goods of this character, which has just been issued by the New York Gas & Electric Appliance Company, 569 and 571 Broadway, New York City. The publication is known as "Catalog No. 18," and its contents are copyrighted. It illustrates an extensive line of gas, electric and combination fixtures, brackets, pendants, domes, portables, electroliers, indirect and semi-indirect lighting fixtures for commercial as well as for residential purposes, electrical appliances, gas goods, glassware and general supplies. The catalog measures 11 x 8 1/4 in. in size, thus permitting the use of a number of illustrations to the page. The early portion of the catalog shows extensive lines of electric showers finished in a great variety of effects and constituting noticeable features of the interior fittings of a room. The line of Craftsman wrought-iron fixtures is also a striking feature of the catalog. There are several pages showing fixtures printed in colors, thus affording the prospective purchaser an idea of the actual appearance of the finished goods. The designs relate to fixtures for gas as well as electric lighting, and the assortment shown cannot fail to prove exceedingly interesting to prospective purchasers. At the close of the catalog is an alphabetical and a numerical index, thus greatly facilitating reference to any design required.

Specifications for Installation of Stewart Furnaces

For the purpose of facilitating the installation of Stewart furnaces, Fuller & Warren, Troy, N. Y., are furnishing specifications and sketch blank which are to be filled out by those desiring information as to size, style and price of the furnaces for heating a certain building, also size and location of warm-air pipes, registers, etc. The company points out that the more care the person takes in answering the questions enumerated and making the sketches the more accurate will be the plans submitted. There are two sheets of tracing paper for the purpose of making a tracing of the basement and second-floor plans, also a page which is to be used for making a plan of the first floor, this being drawn with squares, each of which represents 1 sq. ft. The shape and size of each room are to be clearly indicated, also the location of partitions, windows, doors, chimney, etc. On the last page are shown plans of the basement, first floor and second floor of a building, with the heating and ventilating equipment clearly indicated. Messrs. Fuller & Warren state that their heating and ventilating department is ready to consult with prospective clients regarding their problems and proper plans and specifications for the most approved and economical method of heating and ventilating any work they may have for it. For such service no charge is made.

The New Speakman-Stratton Mixing Valve

It is generally recognized that there are few questions at the present day which are being given greater consideration in the business world than those of efficiency and standardization. By the business world is meant not only manufacturing and selling, but also the professional man as well. The architect, for instance, is sure to find himself involved by the changes and new methods which these questions bring about. His filing cabinets are standardized and brought to higher efficiency for him by the cabinet makers. The materials with which he works are standardized. His business in all lines in so far as it concerns the material object with which he deals is tending in the same direction. The present desire to carry standardization and efficiency principles into effect is well illustrated by the new mixing valve now being placed upon the market by the Speakman Supply and Pipe Company, Wilmington, Del., and a general view of which is presented in Fig. 9. It appears that some time ago W. B.

A Sensible, Safe Construction

We've been at your service for the past twenty-seven years, and we believe by working with architects and contractors on thousands of Store Fronts—of practically every type—we are competent to co-operate with you.

During the wonderful development of Store Fronts we've never attempted to market a "freak" construction—we've "kept both feet on the ground," with the result of a universal confidence in our products.

"ALMETAL" construction is our latest achievement. It's born of experience—practical, simple, easy to install, efficient and moderate in price.

The heavy-gauge copper and the creosote-dipped blocks insure permanency and safety to glass. Show-window ventilation is also well provided for.

If you haven't "ALMETAL" details on file, we'll gladly send a set. A card will do—no obligation.

THE W. J. CLARK CO., Salem, Ohio, U. S. A.

Stiatton, a Detroit architect, found it necessary to specify mixing valves for the use of surgeons in the Detroit General Hospital. There were a number of mixing valves of American make as well as some of foreign design from which a choice could be made; he arranged a series of tests to determine which was best adapted to the work. There were eight different valves, three of them foreign made, which were compared as to the following requirements: 1st, perfect control and grading of full range of temperature; 2nd, ease of cleaning the fixtures; 3rd, minimum liability of the fixtures getting out of order, and 4th, simplicity of parts and ease of repairs. The result of this test was the evolution of a new design based on the mechanical con-

Fig. 9—The New Speakman-Stratton Mixing Valve

struction of the Speakman valve—one of those used in the test. It is this new standardized design that is now being placed on the market under the name of Speakman-Stratton mixing valve. The interior construction of the valve is very simple, the only working parts being the cylindrical mixing chamber and the spindles. The latter, with washers, close with the pressure, while the cylindrical chamber acts as a cam to open the discs. The exact regulation or measurement of water is insured by the port openings in the cylinder traveling across the openings of the water supply. The statement is made that the mixing of water is such that a thermometer placed in the jet shows a regular gradual rise in temperature as the lever handle attached to the valve is swung. This valve is said to mark a decided step in the advance of the standardization of hospital appliances.

Keystona Flat Finish

A handsomely printed pamphlet of sixteen pages illustrated with numerous interior views in colors of delicate hue and relating to the merits of Keystona flat finish which it is claimed "goes on like paint, looks like wall paper and can be washed if desired," has been issued by the Keystona Varnish Company, 2010 Keystona Building, Brooklyn, N. Y. Within the covers of the work the statement is made that Keystona is a washable linseed oil paint for all interior painting that dries without a gloss. Where this flat finish is used the claim is made that walls may be washed and cleaned with soap and water just the same as windows and floors. It is said to be easy to apply, is germ and vermin proof, and retains its color permanently. It can be applied over woodwork as a finish, as an under-coating for enamel, a ground work for staining, glazing and graining, and on metal ceilings, wallpaper, burlap, canvas and galvanized iron. A double page in the center of the booklet carries thirty examples in colors of the various tints which can be produced. Six of these are intended for ceilings, twelve for walls of bed rooms,

(Continued on page 82)

This Kellastone Stucco Was Applied in Freezing Weather

IT'S simply this: that *Kellastone* is the only stucco in existence that can be successfully applied in cold, freezing weather with the absolute assurance that it will not crack, fall or break off. Kellastone is immune to expansion and contraction due to temperature changes. Whatever the temperature, the perfect result is the same. This is because it is mixed with a chemical solution, instead of water.

KELLASTONE

IMPERISHABLE STUCCO

It is not affected by the normal settling of walls. It bonds perfectly with stone, wood, tile, brick or other building material. There'll be no cracks or breaks around door and window casings.

Kellastone overcomes normal stresses, defies climate, moisture, rain, fire and the lapse of time, and preserves its new appearance for years. It may be applied in all of the finishes obtainable with any other stucco, and, in addition, it is the only stucco that can be successfully dry dashed—producing granite and marble effects.

Kellastone is used by the U. S. Govt., and on big buildings, hospitals, schools, railroads, and finest homes everywhere.

Kellastone Composition Flooring solves the flooring problem. It has no seams, cracks or joints, deadens sound and wears indefinitely. Superior to concrete, tile, wood or other flooring. Used in factories, shops, schools, public buildings, homes.

You ought to know more about wonderful Kellastone. Write today.

The National Kellastone Co., 506 Association Bldg., Chicago, Ill.

Pete Says:

"There's as Much Difference in Sharpening Stones as there is in Tools."

THERE are some tools that fall down on the job, there are others that give service—it's the same with sharpening stones, there are some that merely rub the edge on the tool, that fill and won't hold their shape and then there are

Carborundum Sharpening Stones

Clean and quick-cutting, positively uniform and they won't glaze if properly used. They hold their shape, show long life, always ready for work.

There is nothing harder, sharper or faster-cutting than Carborundum

Folder Illustrating Smith Mixerette Concrete Mixer

The T. L. Smith Company, 3120-X Hadley Street, Milwaukee, Wis., has just gotten out an attractive Smith Mixerette—the smallest of the line of Smith concrete mixers. This machine has a capacity of 3 cu. ft. of mixed concrete per batch, or approximately 5 cu. yd. of mixed concrete per hour. The possible combinations of the machine include the Mixerette equipped with either power charger, gated batch hopper or 16-in. low-charging platform; also the Mixerette with hoist mounted on truck between engine and mixer drum. This last combination is referred to as a most excellent little rig for either the building-contractor for hoisting his concrete, brick, mortar, etc., or for the silo builder in erecting silos.

Kahn Road Book

The Trussed Concrete Steel Company, Youngstown, Ohio, is sending out an attractively printed and illustrated publication of 128 pages, entitled "Kahn Road Book." It is devoted to concrete roads and pavements, and refers to Kahn mesh for reinforcement, Kahn armor plates for joints, curb bars and edge protectors, etc., etc. The illustrations are numerous, consisting for the most part of halftone engravings.

The Fine Art of Enameling

An interesting book which deals with the art of enameling has recently been published by the Kohler Company of Kohler, Wis. Few people have any idea of the process of enameling the iron castings of bath tubs, lavatories and sinks, and fewer still know anything about the history of enameling.

This interesting book, entitled "Kohler of Kohler," traces briefly the progress of enameling from the time of the early Phoenicians down to the present perfected method employed in the great Kohler plant. The book is profusely illustrated, the color plates showing the construction of a bath tub from the time the pig iron is lifted by the electric magnet, through the various stages of its completion until it is ready for shipment. To anyone who has never been in such a factory as that of the Kohler Company the description and illustrations of the casting, enameling, etc., will be most interesting. Those, too, who are informed concerning the art of enameling will find the book well worthy of perusal. In addition to the interesting story of the development of enameling the book contains a comprehensive catalog of Kohler products. It is sent free to those who write for it.

TRADE NOTES

Federal trucks played a conspicuous part in the recent mobilization of the various National Guard units throughout the country. In New York City, for instance, the Seventh Regiment was presented with nine Federal trucks, purchased by the veterans of the regiment. The trucks were used to deliver transport army stores and equipment from the armory to Jersey City.

H. W. Johns-Manville Co., with Minneapolis office at 18 Eighth Street, South, made an exhibit of asbestos products at the recent annual convention held in that city by the National Association of Stationary Engineers.

The usual quota of interesting information relative to products manufactured by the Richards-Wilcox Mfg. Co., Aurora, Ill., is contained in the September issue of *Doorways*. In addition, there is a clever editorial on "The Honor Standard—Reputation," which states

(Continued on page 84)

Contractors, Builders, Carpenters!

Why shouldn't *you* get the profit on Ready-Cut Houses erected in your locality? Permanent Ready-Cut Houses are growing in popularity all the time. More and more people are buying them. There are 10 persons in every locality who would be interested in a Ready-Cut House to one who might *build* a house. You might as well get the profit. If you don't, some mail order house will.

I have a very special proposition to offer to you. Will you write?

E. R. MORRIS, 1321 Peoples Gas Building, CHICAGO, ILL.

Grimm's Galvanized Corrugated Wire Lathing

"Note the V"
(Pat. Applied for)

requires no furring on account of the V-shaped corrugations which are imbedded at intervals of seven inches.

This feature alone is worth considering but that's not all. It **WILL NOT RUST** as it is heavily galvanized with the finest grade of Western Spelter and is much easier to handle and will conform to irregular curves much better than any other form of metal or wood lath.

Walls or ceilings plastered on this lathing **WILL NOT CRACK OR DROP OFF**, owing to its great keying qualities, which we will explain if you will drop us a card asking for our booklet No. 61 and samples.

We also manufacture Greening's Patent Trussed Steel Wire Lathing, "Buffalo" Crimped Wire Concrete Reinforcing, "Buffalo" Wire Cloth of all kinds and Wire and Artistic Metal Work for all purposes. **DROP US A LINE AT ONCE** and ask for Catalog 8-H.

Pullman ALL STEEL Unit Sash Balances Noiseless

Is the word that describes the operation of the Pullman Unit Sash Balance. All parts are in the casing—nothing can rub or interfere with the spring action. There is nothing to squeak, rattle, bang or stick. Once installed and it will never require contractors', builders' or architects' attention. There is in every Pullman Sash Balance satisfaction for owner and builder alike. Guaranteed for 10 years.

Our catalog with blue print gives full particulars. May we send one?

new work

Box frames unnecessary

Mortises cut at mill reduce cost of installing. Counterbalance sashes at any given point. They outwear ordinary weights and cords. Unaffected by atmospheric conditions.

Cheapest method for modernizing old windows, as alterations in sashes and frames are not necessary. Sashes should be weighed before ordering.

Write for circular

Caldwell Mfg. Co., 5 Jones St., Rochester, N. Y.

very strongly the advisability of buying only products of known reputation and value.

Richard W. Proctor, son of the proprietor of Buck Brothers, edge tool manufacturers, Millbury, Mass., died at his father's summer home at Falmouth Heights, Mass., on Aug. 20 after a brief illness. Mr. Proctor associated himself with his father about eleven years ago and had advanced by strict attention to business to be superintendent and manager. He was well known to the hardware trade, especially in New York City, where he visited several times a year.

The sixth anniversary of the Federal Motor Truck Company was announced in the last issue of the *Federal Traffic News*. This publication is mailed free to any contracting builder interested in motor trucks. The striking feature of this publication is the rotogravure section, which appears as an insert in this issue. This is said to be the first rotogravure section ever published by any truck company. It is a pictorial section, showing fifty or sixty Federal trucks in action, typical scenes, such as one would see in the supplement of his Sunday newspaper.

Keasbey & Mattison Co., Ambler, Pa., and with Minneapolis office at 427 Washington Avenue, North, made a display of Ambler asbestos roll fiber felt at the recent convention of the National Association of Stationary Engineers held in Minneapolis.

John A. Berger, one of the founders of the Berger Mfg. Company, Canton, Ohio, maker of sheet metal building products, died Sept. 8 at the age of 69 years. He retired from actual business several years ago.

The many merits of oak flooring are set forth in an attractive folder being sent out by the Oak Flooring Bureau, 1349 Conway Bldg., Chicago, Ill. An interesting testimonial as to the added value of oak over an inferior flooring is given in the statement that of two sister houses, side by side in Chicago, the one with oak flooring sold for \$2,000 more than the other.

Elimination of friction in the bearings of a motor vehicle is very important, and the contractor or builder who uses one in connection with his business will therefore be interested in the following item taken from *Graphite*. Hauling hot asphalt is not an easy job even for a five-ton truck, and for about a year a fleet of fourteen such trucks averaged one broken wheel bearing per week. In September, 1914, it was decided to use Dixon's graphite, made by the Joseph Dixon Crucible Company, Jersey City, N. J., mixed with grease. Since that time it is said that not one broken bearing has been reported, which is an excellent testimonial of the value of this lubricant.

The International Roofing Mfg. Company, 5301 South Western Avenue, Chicago, Ill., will erect a one-story warehouse, 66 x 200 ft., to be built of combination tile and concrete slabs. Trusses made by McKeown Bros., of Chicago, will be used and the roof covered with prepared roofing. The cost will be about \$16,000 and bids are being received by Engineer N. Ronneberg and Architect R. G. Pierce, Otis Building, Chicago, Ill.

The Wheeling Corrugating Company, Wheeling, W. Va., is preparing plans for a large garage in Chicago to be built next to its new plant at Campbell and Arthington Streets. The garage will contain the latest equipment for the handling of industrial automobile shipping. It will accommodate some of the largest built trucks and is entirely in keeping with the rapidly growing business of the company's Chicago branch. The building will cost \$50,000 and is designed by Paul Gerhardt, architect, Chicago, Ill.

The Pecora Paint Co., Fifth and Venango Streets, Philadelphia, Pa., is sending out a series of pamphlets of interest to the builder, and entitled "Pecora Mortar Stains," "Pecora Blue Black Cement Stain," "Pecora Calking and Elastic Glazing Compound," and "Pecora Weathertite Elastic Cement." The last named booklet is especially interesting to the practical builder as it describes various unusual tests to which "Pecora Cement" has been subjected.

MR. BUILDER:—Increase Your Income Right Now—This Month

Here's something right in your line—a Chemical Closet that you can sell to a home builder cheaper than a wooden privy and make a bigger profit for yourself. Here's something you can sell at odd times or turn over to your son or your foreman to sell.

RO-SAN Chemical Closet

An absolutely sanitary, odorless indoor closet that may be placed anywhere in the house. Abolishes the germ-breeding outdoor vault. A comfort and a convenience where there is no sewer connection. Germs killed by chemical. Easily emptied as the ash pit of a stove.

AGENTS WANTED

We want one live carpenter contractor in each town to act as our agent. Hundreds of builders are selling these fixtures. Good profits for little work. We help you sell them. Write today for complete details.

Rowe Sanitary Mfg. Co., 1003 Sixth St., Detroit, Mich.

Ask about the Ro-San Washstand. Hot and cold running water without plumbing.

4 Steel Corner Plates

give an *absolute rigidity* to the Dietzgen "STURDY" Knock-Down Drafting Tables, permit of quickly setting up, taking down or compactly crating for transporting at reduced cost.

The Frame is thoroughly seasoned hardwood, highly finished.

The Top is a white pine drawing board, 33x63x1¼ in., with or without drawers.

The Height is 34 inches, adjustable with raising blocks to 35, 36 and 37 inches.

Send for Circular "B-1."

Your Own Eyes Will Tell You Why!

One glance at those two sturdy legs—not one, but two—will tell you why "Trouble Saver" Brackets are absolutely stable. Just note how one leg braces against the other, thus preventing all side motion. Your men will feel as secure on "Trouble Saver" Brackets as on any part of the house.

Then there is another feature you cannot notice, but you will appreciate when erecting the scaffolding—you can erect as many "Trouble Saver" Brackets in five minutes as you can wooden brackets in five hours. No bolts, no nuts, no nails—not even a screw.

But don't depend entirely on your eyes. Try a few. We will lend them to you. Write for particulars.

The Trolley Track

Long use and years' experience have proven the box-shaped trolley track No. 31 and No. 35 types the most satisfactory.

This type track provides two runways on which the carrier wheels roll, thus distributing the load; protects the hangers from the weather, is bird-proof, jump-proof and trouble-proof.

Sold in 4, 6, 8 and 10-foot lengths.

The Hanger

From a mechanical standpoint, the perfect design for a door hanger is the center hung type—used only in No. 31 and No. 35 types trolley track.

The four hanger wheels roll in the two smooth runways in the track; from the exact center of the two axles, which connect the four wheels, a pendant suspends to which the aprons which hold the door are attached. Thus the load is suspended from the exact center of the hanger—any variation of the door off center of gravity does not affect the easy movement of the hangers on the track.

Why not give your clients the best when it costs no more?

"You can't expect Beaver Board results unless this trade-mark is on the back of the board you buy."

"Beaver-Boarding"
is a Carpenter's Job

Get that idea.
"Beaver-Boarding" is a carpenter's job.
Not a job for the plasterer or paper hanger.
Every Beaver Board room or alteration means work for the carpenter or carpenter-contractor that he wouldn't get if lath and plaster were used instead.
And it means, too, a more satisfactory job for the owner—a neater job, one that is done more quickly, and that will last almost indefinitely.
Nothing goes into Beaver Board but pure wood fibre. It's reconstructed lumber—seamless and knotless. Works up splendidly.
Ask us about our *free* design and decoration service.

Factory in Chicago for West

Prepare for Winter

but don't put up the old stove

The HESS Welded Steel Pipeless Furnace. No horizontal pipes nor air ducts in cellar.

The Hess steel furnace is sold direct to contractors and consumers, but is not offered through dealers nor agents. Specially low prices, therefore, are possible, and very many contractors throughout the United States are purchasing Hess furnaces for themselves and for their clients. Installation is easy, not requiring the services of special mechanics.

THE HESS PIPELESS FURNACE supersedes the base burner, costs no more, uses less fuel, circulates the heat better than stoves or radiators. The entire furnace is enveloped in a down-flowing current of cool air, which returns, heated, to the rooms. Therefore, every particle of heat is used and none is wasted. There are no horizontal pipes nor air ducts, no muss nor dirt upstairs; easy to install and requires little space in the cellar. Suitable for hungalows, churches, stores, etc., but not recommended for two-story houses, for which we supply our regular *pipe* furnace, with separate pipes and registers.

Write for complete illustrated booklet and special contractors' rates.

THAT WOOD CORE

is responsible for the many
desirable qualities of

Trade Mark Reg. No. 94745

Consider first, of course, its chief use as a wall lining, and why, because of its wood core, it is *better* in every way than lath and plaster, stronger, more durable and sanitary.

Because it has 101 other uses, such as:

- lining summer garages and outdoor sheds for warmth.
- lining summer cottages (helps keep them cool).
- quick repair partitions.
- enclosing rooms in attic or cellar.
- building dust proof closets or cabinets.
- panels in wainscoting or beamed ceilings.
- shelves, drawer bottoms, cabinet backs, etc.

Sold by dealers everywhere. Write for free sample and interesting booklet.

Do you realize the flexibility of VanGuilder Hollow Wall Machines?

Double Wall

Do you realize that these machines take care of every angle, bay and other irregularity encountered in any building plan—no fussing with supplementary forms—no patching of walls?

They build anything from a Garage to an Apartment House

Van Guilder hollow wall machines have been used on every type of building construction. They build a two-piece hollow wall reinforced where necessary. A wet mix of concrete is used. Machines are moved forward immediately after being filled, building a continuous 9" wall course with single or double air space.

A Van Guilder Building is "Built Like a Thermos Bottle"

Van Guilder houses are warm in winter and cool in summer and dry all the year round. Plastered direct inside and outside. Van Guilder construction competes in price with frame construction and underbids masonry, brick, veneer and stucco on metal lath.

Write for folder describing Van Guilder construction in detail.

Herringbone Rigid Metal Lath.

For Satisfaction's Sake Specify Herringbone

Every architect and builder has two parties to satisfy—the owner and himself. There is no surer way of doing it in the next house you build than to see to it that Herringbone Rigid Metal Lath is used.

Its stiffness, interlocking edges, wide sheets, perfect key, lightness and strength all combine to make it a most satisfactory lath to the architect, builder and owner.

Send for a copy of the Herringbone catalog, a book of specifications and construction details.

Wright Wire Lathing

In Big Buildings or Small Houses

Which Kind Do You Build?

Do you erect the large ones or the small ones, or both? Whatever the kind, you want to get the very best construction obtainable and that is why you should use Wright Wire Lathing. It is used in skyscrapers and in small houses all over the country. It is fire-proof, sag-proof, and rust-proof. It may be attached to any type of wooden frame work by means of staples and to steel framework by means of tie wire. Be sure to use Wright Wire Lathing in your floors, ceilings and partitions. Write for Catalog X.

Asphalt Shingles Are Economical

The illustration shows a low cost bungalow built by J. C. Lawrence, Harvey, Ill., Architect and Contractor.

Winthrop Tapered Asphalt Shingles

were used because they are economical — being long-lived — beautiful and attractive, and fire resisting. A description of this house will be found in the editorial pages.

They are equally well adapted to larger and finer residences. They will not blow up, warp or burn and the colors are harmonious and lasting.

Any contractor who pushes Winthrop Tapered Asphalt Shingles is building a business for himself.

Don't lay another roof until we send you a sample Winthrop Tapered Asphalt Shingle.

Google

The cup of Sykes Expanded Cup Metal Lath is so formed that the Stucco or Plaster takes a tight grip and holds. A perfect key is assured. No furring strips are needed—this feature saves 5 to 10 cents a sq. yd.

SYKES EXPANDED CUP METAL LATH

Self-Furring

It Is a Veritable Backbone of Strength

Being cut with wider strands, it is heavier than other metal laths of the same gauge and therefore more rigid, stronger—gives a wall longer life.

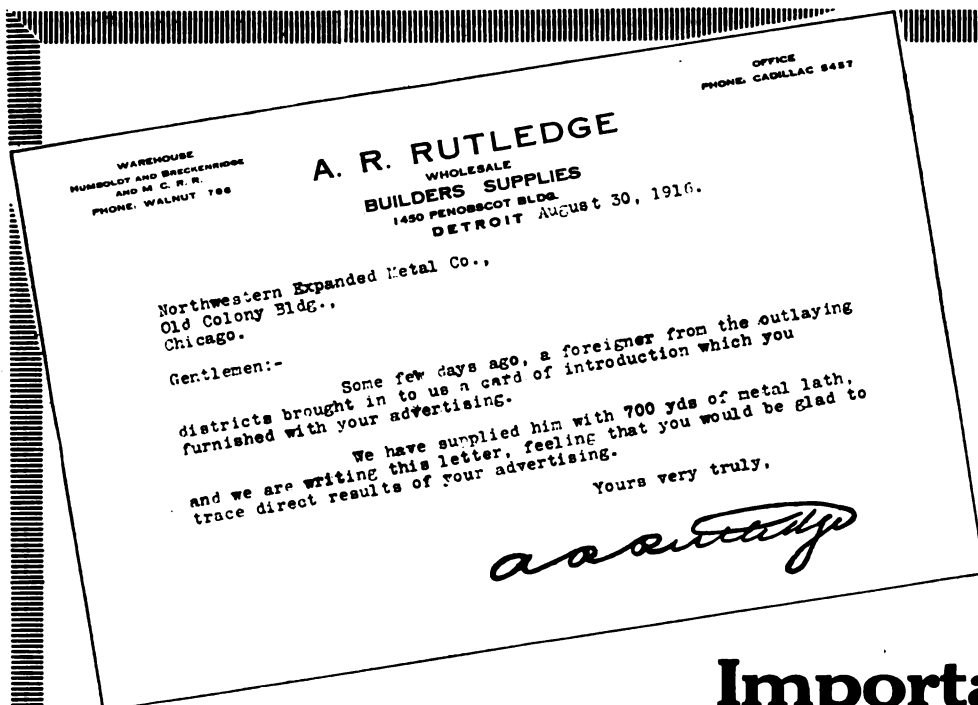

Can't be applied wrong. Best for interior as well as exterior work. Indorsed by U. S. Government for Post Office work. Approved by architects, contractors and builders.

Building Age Colored Perspectives

Do You Want a Set of 27?

WE have a limited number of sets of 27 each of the beautiful three and four-color perspectives, same as those used in various issues of BUILDING AGE.

There has never been an opportunity for getting such a varied collection of beautiful perspectives, and as we have no remaining copies of most of the issues of BUILDING AGE in which these appeared, and as the expense of reprinting them in color—unless in very large quantities—would be prohibitive, it is probably the last opportunity of securing a set.

We have constant inquiries from subscribers for these prints separate from those bound in the magazine. Many frame them; others use them as suggestions. While they last we will send a set for one new subscription, or for renewal of your subscription for one year from date to which it is now paid; two dollars to accompany order, or enclose a dollar bill at our risk for the set.

Address orders to—

EVERLASTINGLY GOOD

That's the biggest point to remember about FLEX-A-TILE Asphalt Slab Shingles.

FLEX-A-TILE Diamond Point Slab, Laid in American Diamond Style

More important than their actual, immediate saving in material, labor, nails and freight is this proved fact: *They are the most enduring roofing on the market.*

If you want a reputation as a builder whose work *lasts*—who has customers come to him instead of he going to them—roof *permanently* with

FLEX-A-TILE ASPHALT SLAB SHINGLES

All FLEX-A-TILE Shingles are made with the same exacting, scientific care that has made the name "Heppes" standard in asphalt roofing.

Pure wool felt is saturated with twice its weight of high-melt, oil-free asphalt; over this we lay a coating of tough, rubber-like gilsonite, and into this is compressed under tons of pressure the beautiful crushed slate or granite surfacing. The result is a shingle that wears like iron—cannot rot, rust, split or curl, and only grows richer in color with age.

FLEX-A-TILE Reversible Slab, Laid in American Shingle Style.

Save { 50% in Labor
35% in Freight
38% in Nails

No time is wasted in chalklining — FLEX-A-TILE Slabs automatically space and gauge themselves. Only five nails are needed for every four shingles. Their shape means less weight and consequently less freight.

Send for a Free Sample

You must see these shingles in their actual colors of red and green to realize their beauty. Just drop us a line mentioning your business and we will forward liberal samples, prices and complete information.

FLEX-A-TILE Style 4 Slab, Laid in American Shingle Style

Good Agencies Still Open — secure the facts on our proposition. Write *today*.

Many localities still need a live agent to gather in the profits from selling FLEX-A-TILE products. Write and

Flex-A-Tile Roll Shingle—Utility Board—No-Tar Asphalt Paint

Other Guaranteed Heppes Products

Useful, Beautiful—and Purchasable!

Is it practicable? Is it beautiful? Can you buy it? Everything published in *House & Garden* is subjected to these three tests. Out of the millions of beautiful things in the world, *HOUSE & GARDEN'S* editors choose those that in their beauty, their usefulness, and their price are attainable by you for your home, rejecting rigidly everything that is beautiful without being practicable, or useful while ugly, or practicable and beautiful but unattainable by the American citizen.

It not only maintains a high standard of artistic excellence, but it insists on knowing by whom, at what cost, each thing is made. It gives prices, states terms, and explains just where and from whom and for about how much you can procure anything and everything described in its pages. This, we believe, is the most valuable service we can render to our readers, who buy *HOUSE & GARDEN* not merely to read but to use.

The Advice of Specialists

Thousands of people are designing and making the most fascinating new things for *HOUSE & GARDEN*—for *your* house and garden. It is our business to know them all. Will you remodel your town house? *HOUSE & GARDEN* will bring you the last word in architecture. Do you need a vase for a single rose?

Here it is! Would you like help about the living room paper, or a pet Airedale, or a scheme for a tiny city garden to be lovely all winter long? Our experts are at your service.

The Shops of the World

Moreover, *HOUSE & GARDEN* not only shows and suggests, but actually purchases for those of its readers who are too far away or too busy to visit New York and shop for themselves. It gives such full information about prices and qualities that you can judge the precise value to you of everything shown in its pages, and through its Information Service and its Shopping Service it will settle any doubtful point or make any particular purchase you may desire.

House & Garden Suggests That

\$1 Invested in Six Months of Our Skilled Counsel

May Save You \$100—Perhaps \$1,000

Just one casual dollar—an inconsiderable fraction of the price of one ill-chosen chair—will bring you our staff of experts for six delightful months. Connoisseur, architect, kennel expert, landscape gardener, interior decorator, sanitarian, saleswoman and friend, are all packed between the covers of *HOUSE & GARDEN*. Fill out the coupon opposite, and let us start your trial subscription with the October Number. You will get six issues crammed full of all you need to know to make your winter pleasant and your garden full of jonquils in the spring. Surely a dollar never worked so hard for you before.

HOUSE & GARDEN, 445 Fourth Avenue, New York City
 Send me six numbers of *House & Garden*, beginning with the
 October Number, for which I enclose \$1, herewith (OR)
 enter my subscription for the next five numbers, beginning
 with October, and I will remit \$1 on receipt of bill.

FREE 224 page Plan Book and year's Consulting Service given absolutely FREE with every set!

This is one of the most liberal offers ever made. We give free to every purchaser of our newly-revised *Cyclopaedia of Architecture, Carpentry and Building*, a copy of "Modern American Homes," the most complete and up-to-date plan book procurable. It contains plans and specifications for 168 different structures, including excellent exterior and interior views, detailed estimates, etc. Designed by the leading architects of this country, it includes city, suburban and country homes, bungalows, summer cottages, tent houses and camps, also apartment houses, garages and various public buildings. Contains 224 pages, 9½ x 12¾ inches, and 426 illustrations. Printed on heavily enameled paper and substantially bound. With this great plan book in your shop or office you are prepared to figure on any job, no matter how large. No need for the prospective builder to consult an architect when you can offer him his choice of practically every type of the modern American home. This saving of the usual architect's fee should get you the business.

In addition to this we give free with each set a year's consulting membership in the *American Technical Society*. Through this service you have the assistance of the most expert architects, structural engineers and draftsmen in America. They are no farther from you than the nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. In fact, they enable you to compete with the biggest and most experienced men in the construction field.

The Newly-Revised Cyclopaedia of Architecture, Carpentry, and Building

This is the clearest, most practical and complete work ever published on the practice and possibilities of the modern building trades. The 1916 edition covers everything from cottage to skyscraper—from the plans to the completed structure. It includes wood, stone, steel and reinforced concrete construction; estimating and contracting; a study of the Greek and Roman orders; interior finishing and

decorating; and modern house lighting and sanitation. The work of forty experts, it can be depended upon to give you the information you desire on any and every subject. Every line written in simple English—every technical point made plain.

The ten large volumes are handsomely bound in half morocco, gold stamped, and contain 4,760 7x10 inch pages; 4,000 illustrations, full page plates, building plans, diagrams, etc.; hundreds of valuable tables and formulas, carefully cross-indexed for quick, easy reference.

Entire Eleven Volumes Sent Free

That you may judge for yourself the value of the plan book and this wonderful reference work, we will send the complete eleven volumes to you for seven days' free examination, express prepaid. Look them over carefully—make use of them at your work for a week—then if they fail to meet with your expectations they may be returned at our expense. If you keep them, send us \$2.00 within seven days and \$2.00 a month until the specially reduced price of \$24.80 on the *Cyclopaedia* has been paid. Remember—the consulting membership and plan book are included absolutely free of charge.

Can you afford to let \$2.00 a month stand between you and hundreds of dollars in increased profits? The consulting membership alone is worth many times the first cost of the books. Decide to equip your shop or office with this business getting combination. Fill in and mail the coupon—now!

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

National Sheet Metal Roofing Co., 339-345 Grand Street
JERSEY CITY, N. J.

Don't Miss This Opportunity

We Want One Representative in Every Community to demonstrate, Take Orders for and Apply Our EDWARDS METAL SPANISH TILE ROOFING on a Liberal Commission.

Here is a chance to build up an independent, profitable business for yourself right at home. Many are now devoting their entire time to selling our metal roofing. Others have made big profits simply devoting part of their time to selling and laying our Metal Spanish Tile.

Edwards Metal Spanish Tile

Is being advertised in the leading magazines and is now known to thousands of home builders and owners everywhere. Wherever it has been used it has made a decided "hit" because it shows off to good advantage on the roof and has numerous points of superiority over any other style of roofing.

Architects are specifying Edwards Metal Spanish Tile, for they know it will do away with roofing "Troubles." Builders like it because of the finished appearance it gives any house on which it is used.

Our Metal Tile are stamped out of the highest quality Worcester terne plate in exact imitation of the most expensive Terra Cotta Spanish Tile. They come either "dip" painted or heavily galvanized size 10 x 14 inches. Our patented interlocking side lock makes it possible to make a perfectly moisture-proof roof without soldering. Edwards Metal Spanish Tile afford the fireproof advantages of Terra Cotta Tile, but are much lighter in weight, cost but a trifle more than ordinary roofing and will last a lifetime.

WRITE US TODAY ABOUT YOUR TERRITORY. Our business is growing so rapidly that it is necessary to have an agent in every community. The territory is going fast. One day's delay may mean that some one else will be given your territory. DON'T DELAY. WRITE TO-DAY FOR OUR SPECIAL AGENTS' PROPOSITION.

Note the construction of patented interlocking device, protecting nail heads from weather and providing perfectly for expansion and contraction of the metal.

BRANCH AT KANSAS CITY, MO.

MILWAUKEE, WISCONSIN

Residence of Mr. H. Fisk, Green Bay, Wisconsin. Architects: Foeller & Shober, Green Bay, Wisconsin.
Roofed with Ambler Asbestos Shingles, "Century Brand."

This Roof Emphasizes the Artistic Attributes of

Ambler Asbestos Shingles, "Century Brand." In this instance, they were chosen as much to complete the tasteful contrasts predominant throughout the building as for their fireproofing and last-forever qualities.

AMBLER **Asbestos Shingles**

The Roof That Is as Permanent as the Foundation

This roof will remain intact throughout the life of the building. The repairs incident to slate, tile and tin roofs are eliminated. Preservatives and paint are never necessary. A peculiar quality of asbestos is that it becomes harder, tougher and improves in serviceability and appearance under the weathering influence of the elements. Its light weight also effects an additional economy both with respect to rapidity of roof construction and the use of lighter timber than is possible in connection with slate or tile.

Ambler Asbestos Century Shingles are made of the best grade Portland cement, reinforced by Asbestos fibre, the whole thoroughly integrated by special process to secure a dense, uniform, homogeneous texture. They will not crack or split. They obtain in various shapes and in three colors—Newport Gray, Indian Red, Blue Black, making possible those combinations peculiarly identified with certain types of buildings. They serve the artistic requirements from cottage to castle and are in use by this and foreign governments.

Send for the evidence of Artistic and Structural attainment as contained in our illustrated catalog.

Keasbey & Mattison Company
Dept. B-2 Ambler, Pa., U. S. A.

PROVIDE the walls and ceilings of your buildings with a secure foundation to receive the stucco and plaster and hold it firmly in place.

You will eliminate unsightly cracks and falling plaster by using

Berger's Expanded Metal Lath

The small diamond-shaped meshes allow a perfect "key," completely imbedding the lath in the plaster, giving great strength with the minimum amount of plaster.

Berger's Expanded Metal Lath does not absorb moisture, hence cannot swell, warp or stain the plaster. It is *fire resisting*, vermin and sound proof, and prevents rats and mice from making holes through the walls.

It is free from sharp edges to cut and injure the hands and can be easily formed into small members for cornices, coves, beam covering, column covering, etc.

The large sheets (8 feet long and 18 and 24 inches wide) make application speedy and easy.

Used extensively and effectively for plaster, stucco and "overcoating" old houses.

Berger's Corner Beads insure a smooth corner to which the plaster properly adheres. Prevent plaster from cracking or chipping at the corners. Also good for stucco work.

Berger's Base Screed, permanently applied, affords a secure ground for the plaster above and the cement base below, protecting both at all times. It makes a perfect job and saves time.

Have You a Starrett Combination Square?

It is the one tool that every carpenter and cabinet maker should have. It helps you to do better work and faster work—it can be used as a rule, square, level, bevel, and even as a depth gage, height gage, or marking gage. Isn't that a tool worth having?

Starrett Tools

Are all accurate and well made—they will help you in laying out and measuring your work. Among the fine tools we make for carpenters you will find rules, squares, steel tapes, scratch gages, cabinet scrapers, nail sets, trammels, compasses, etc. You can see them all at any good hardware store.

Write for free catalog No. 21P, describing the full line and giving prices.

CON-SER-TEX

is the most economical material to lay on porch roofs, floors and sleeping balconies. It is the ideal covering for all flat surfaces or whenever the pitch is less than four inches to the foot.

CON-SER-TEX is a scientifically treated cotton fabric that sheds water perfectly and will not rot, shrink, stretch, curl or peel.

It is easy to lay—clings to the surface, makes a neat, clean, smooth, durable covering. When properly laid it will last as long as the house itself.

Send for our new illustrated booklet, "ROOFING FACTS and FIGURES." It will show you how CON-SER-TEX can be used to advantage—how you can save money by installing it, and will give you some new ideas on lining wood box gutters, covering valleys and hips and making durable, cheap, satisfactory flashings. CON-SER-TEX has rendered satisfaction on thousands of homes in all parts of the country.

Bay State "Agatex"

Makes Better Cement Floors

Rough cement floors have a tendency to be damp, to dust and to wear away unevenly. Dampness and dust are detrimental to health and comfort and to the room's contents. These drawbacks are easily overcome by using Bay State "Agatex."

This is a cement floor filler which is wearproof, dustproof, oilproof and water-proof. Easy to apply and economical.

One gallon will coat 400 to 450 square feet on floors of ordinary texture and condition. Bay State "Agatex" is extremely long wearing.

Write for circular 19 giving detailed information about Bay State Agatex.

Double Wall

Do you realize the flexibility of VanGuilder Hollow Wall Machines?

Do you realize that these machines take care of every angle, bay and other irregularity encountered in any building plan—no fussing with supplementary forms—no patching of walls?

They build anything from a Garage to an Apartment House

Van Guilder hollow wall machines have been used on every type of building construction. They build a two-piece hollow wall reinforced where necessary. A wet mix of concrete is used. Machines are moved forward immediately after being filled, building a continuous 9" wall course with single or double air space.

A Van Guilder Building is "Built Like a Thermos Bottle"

Van Guilder houses are warm in winter and cool in summer and dry all the year round. Plastered direct inside and outside. Van Guilder construction competes in price with frame construction and underbids masonry, brick, veneer and stucco on metal lath.

Write for folder describing Van Guilder construction in detail.

Why Don't You Get a Barnes Hand Circular Rip Saw?

Sawing by hand is "backbreaking" work—sawing with our machine prevents the aches, and requires no skill.

One man with a Barnes Hand Circular Rip Saw can easily rip (line measure) 600 feet of one inch pine in an hour, or 6,000 feet in 10 hours.

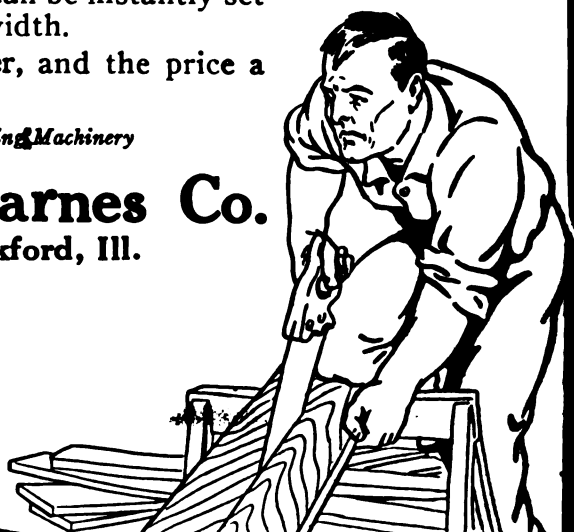

It will rip boards or planks of either soft or hard wood, of any thickness up to $3\frac{3}{4}$ inches and any width up to 19 inches.

Feeds slow or fast as desired; can be instantly set to or from the gauge to any width.

The Barnes is a money maker, and the price a money saver.

Send for Catalog of Wood Working Machinery

W. F. & Jno. Barnes Co.
71 Ruby Street, Rockford, Ill.

Start Your Shop With This Machine!

**FAY-EGAN "LIGHTNING" No. 330
Variety Saw**

**With Hollow Chisel Mortising and
Boring Attachment**

- It will do all your ripping, cross cutting, miter and bevel sawing, gain, groove and cut tenons, bore, rout, and cut any kind of mortise.
- You'll find many other uses for the "330"—it's just the machine to start a shop—soon pays for itself—and makes the money to pay for a Jointer—Surfacer—Band Saw—and Lathe—which you can add one at a time to complete your equipment.
- That's one advantage of the single unit idea—you start little and grow big along just the lines on which your work develops—and in the end have a real practical and profitable shop.
- No. 330 can be driven from line shaft, gas engine or self-contained motor.

Write for Bulletin and Prices—also Catalog of other small shop machines

"the best mixer of mortars I have ever seen or used"—

So says Willard Myers, Bricklayer and Builder, 2000 E. Cambria St., Philadelphia

The LANSING ADVANCE MORTAR MIXER

is NOT a concrete mixer made over, but designed and built as a mortar mixing machine—one reason why it does its work well.

Saves TIME and LIME. The Lansing Advance with one or two men will do the work of six or eight men with hose—and do it much better. Economical for 5 or 6 masons or for 60.

With about $\frac{1}{2}$ less lime, the mortar is richer and stronger than can be mixed by hand. Every lot is absolutely uniform, smooth and easy to work. Each mason will lay 200 to 400 more brick a day, when you mix the mortar by the Lansing Advance.

Nearly all the largest buildings in recent years have been put up with mortar mixed by the Lansing Advance. This machine is built right. Simple, trouble-proof construction; ample power.

ASK ANY CONTRACTOR WHO OWNS A LANSING ADVANCE.

Prepare for Winter

but don't put up the old stove

The HESS Welded Steel Pipeless Furnace. No horizontal pipes nor air ducts in cellar.

The Hess steel furnace is sold direct to contractors and consumers, but is not offered through dealers nor agents. Specially low prices, therefore, are possible, and very many contractors throughout the United States are purchasing Hess furnaces for themselves and for their clients. Installation is easy, not requiring the services of special mechanics.

THE HESS PIPELESS FURNACE supersedes the base burner, costs no more, uses less fuel, circulates the heat better than stoves or radiators. The entire furnace is enveloped in a down-flowing current of cool air, which returns, heated, to the rooms. Therefore, every particle of heat is used and none is wasted. There are no horizontal pipes nor air ducts, no muss nor dirt upstairs; easy to install and requires little space in the cellar. Suitable for bungalows, churches, stores, etc., but not recommended for two-story houses, for which we supply our regular pipe furnace, with separate pipes and registers.

Write for complete illustrated booklet and special contractors' rates.

The HESS Welded Steel Furnace for Separate Pipes and Registers.

HESS WARMING & VENTILATING CO., 1201 Tacoma Bldg., Chicago

A Heating Plant Condensed

Opens Up a New Field for Profit to Contractors

Many houses in your locality can profitably use this new heater and do away with all the trouble, expense and inefficiency of stoves.

You can sell it, for new or old houses. It is so simple that it requires no furnace expert to install it—the buyer can do the work himself. Simply a smoke pipe, and a single register under main room, from which the furnace floods the whole house with heat. It has a strong appeal to farmers and owners of cottages and bungalows, because of its efficiency, low cost and ease of installation and operation. Does not heat cellar.

Write at once for Booklet and our Agency Proposition. It will show you an easy way to add good profits to your business, that you would not otherwise get.

INTERNATIONAL HEATER CO.

THE HAZARD *of* RAISED GRAIN

Is one which some Architects still use as an argument against any southern pine for white enamel treatment, seemingly because of their belief that all such pine is alike.

Raised grain is a contingency only when the enamel is put upon pine of heavy resinous content which must necessarily be shellacked before the priming coat of lead and oil is applied. When the shellac comes in contact with the resinous surface, an uneven absorption occurs, which causes the grain to raise, resulting in an unsatisfactory effect.

ARKANSAS SOFT PINE

interior trim is virtually free from rosin, has a tough fiber, fine close grain and *does not require preliminary shellacking*. Instead, after proper sanding, the lead and oil priming coat is applied directly to the raw wood, allowing a perfectly even absorption. No raising of the grain occurs. When the enameling is completed, the result is a satin-like surface which will maintain its luster and in every detail satisfy the most exacting client.

In addition, this wood is readily obtainable and at moderate cost, due to an abundant supply.

White Enamelled and stained samples on request.
Our Architects' Manual containing data, finishing specifications, grading rules, etc., will fit your file.
Ask for it.

Arkansas Soft Pine is trade marked and sold by dealers. Yours can supply it.

Woods and Their Uses

ALL woods have certain uses for which they are especially adapted by reason of the peculiar qualities and characteristics which nature has given them; and on their proper selection for these uses, hinges the whole problem of economy in wood construction.

Three centuries of experience in this country have demonstrated that no other wood lasts so long or gives such satisfactory service as

WHITE PINE

for outside finish lumber—siding and corner boards; window sash, frames and casings; outside doors, door frames and casings; outside blinds; all exposed porch and balcony lumber; cornice boards, brackets, ornaments and mouldings; and other outside requirements, *not* including shingles.

If the lumber dealers supplying your clients are at any time unable to furnish it, we should appreciate the opportunity of being helpful to you in securing it.

"Stucco Coated frame residence" from July Building Age. Geo. J. Hardway, architect.

"The shingles of the roof were dipped 10" in Cabot's Shingle Stain before being laid, and they were given a brush coat when the house was finished. The stucco finish received two coats of Cabot's Stucco Stain."

Cabot's Shingle Stains

They have been the standard for more than twenty-five years, and are specified by nine-tenths of the architects, who know them from experience. Their colors are soft, rich and beautiful, and guaranteed fast. Their vehicle is Creosote, which thoroughly preserves the wood, and they contain no kerosene or other cheapener. Why experiment with unknown stains, when you are sure of Cabot's?

Cabot's Stucco Stains

are the only artistic cement finishes. They give soft, natural coloring effects, without covering the surface with a painty coating. They are also cheaper than coatings and easier to apply, and they cannot crack or peel.

You can get Cabot's goods all over the country. Send for samples and name of nearest agent.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

BUILDING AGE

NEW YORK, NOVEMBER, 1916

FRONT VIEW OF THE HORSE BARN ON EDELLYN FARM NEAR WAUKEGAN, ILL.

A GROUP OF MODERN FARM BUILDINGS

THE ARCHITECTURE, CONVENIENCE, LIGHTING AND
SANITATION ARE FEATURES OF THESE STRUCTURES

THE contractor and builder who is called upon to design and erect a number of buildings for farm use finds it necessary to include many important points from the standpoint of construction and grouping, with due consideration to the landscape architecture. Modern practice is to arrange buildings convenient to each other and far enough apart to prevent the spread of fire, in which connection prevailing winds are considered. The structures utilized for housing live stock are designed and located with reference to feed supply, while capacity for present needs and the possibility of future expansion are matters which call for an intelligent analysis of the general situation. Sanitary construction, with adequate provisions for lighting and ventilation, are most essential, for clean buildings and plenty of sunshine and air mean healthy stock. Water supply and drainage are factors which cannot be overlooked, while the question of electric lighting for all buildings is made possible by inexpensive equipment, especially

suitable for farm use. Not every farmer is able to afford buildings of concrete or tile, but the cost of farm improvements may be kept within a reasonable figure where a substantial and harmonious combination of wood and fireproof materials is carried out.

An excellent example of a modern farm where all of the foregoing features have been incorporated is found in Edellyn Farm, near Waukegan, Ill. Each building is designed in accordance with its present and future requirements, and exposures are such that prevailing winds and the individual needs of the structure are carefully considered. The result is a grouping that is compact and of exceptionally pleasing appearance. The accompanying farm plan shows the location of the various buildings and their proximity to each other, while the photographic reproductions demonstrate that there is a distinct similarity in the architectural treatment.

Generally speaking, the construction throughout is

LEFT TO RIGHT—HORSE BARN, GARAGE, MACHINERY AND TOOL SHED AT LEFT OF SILO, CATTLE FEEDING BARN AND PIGGERY. POULTRY HOUSE IS HIDDEN BY THE TREES

THE ABOVE IS A SOUTH VIEW OF THE HORSE BARN AND COLT SHED. AT THE EXTREME RIGHT IS THE GARAGE

free from unnecessary posts and structural members that would tend to interfere with the convenient and economical handling of farm products and stock. All roofs and walls of buildings are shingled, the former being dipped a dark shade of green and the latter finished in white, a combination which is harmonious and effective. The roof lines are enhanced by the dormer windows and red brick chimneys, while the doubling of every fifth course of shingles and extension of all rafters at the eaves demonstrate the thought which was given to the architecture throughout. All roof shingles

residence. The implement and wagon shed lies to the northeast of the poultry house and is directly in line with the end of the cattle-feeding barn on the northeast corner. At the south end of the latter is a silo and tank, the barn opening to a large concrete yard on the east side. The piggery is 20 yds. east of the silo and faces south, the runs and feed floor extending in this direction. The garage occupies the southeast corner of the group, to the west of which is the horse barn and feeding shed, with yards, as shown. The pump house is between the residence and the horse barn but nearer the latter and has a door on its west side. On the north side of the horse barn are two additional box stalls connecting with individual yards.

BLOCK PLAN OF THE FARM BUILDINGS

are exposed 5 in. to the weather and wall shingles 11 in. to the weather. Concrete is used exclusively for footings and mostly for floors, though in some instances creosoted blocks and clay floors have been considered more desirable for the conditions under which they are used.

The group consists of a horse barn with a feeding shed running at right angles, cattle feeding barn with adjacent silo and tank, piggery, poultry house, a combination implement and wagon shed and corn crib, milk house, pump house, garage and farm house. Hay mows are provided over the horse barn, feeding shed and cattle-feeding barn, while the latter has also a weighing room.

The farm house is to be found at the extreme west end of the group, but a few steps from the milk house and a short distance from the poultry house, both buildings being very convenient to the

DETAILS OF THE HORSE BARN

The horse barn has a standard width of 36 ft. and is 80 ft. long, the height from the finished floor to the ridge being 38 ft. The building has three entrances, two at either end for the stock and a canopied entrance on the west front, giving access to a passage with rooms on either side. The first floor presents an arrangement of two rows of stalls, running lengthwise of the barn, a feature which enables the two rows to be attended at once in caring for the stock. On the east side are five box stalls, equipped with sliding doors off the alley and half doors to the yard. On the opposite side are two groups of five single stalls, without doors. The box stalls are 12 ft. square and the single stalls 9 ft. long and 5 ft. wide, with 5 ft. partitions 6 in. thick throughout. Each stall is equipped with a 16 x 24-in. feed box, 8 in. deep. Each stall has a large window installed near the partition at a convenient height, opening inward.

The floor plan includes a 10 x 12 ft. harness room, equipped with brackets for harnesses on three sides, and also a sink. A concrete watering trough, 4 ft. long and 2 ft. wide, rests on concrete slabs 18 in. from the floor. In the northeast corner is a feed room, with sliding door having three chutes from the second floor, a passage between this room and the end box stall leading to the feeding shed. This shed is 26 ft. wide and runs to the east for a distance of 57 ft., feed troughs and a concrete watering trough being built as shown on the accompanying drawings. The shed has two openings to the south, communicating with the yard back of the box stalls. The first-floor plan

also provides an 8 x 10 ft. office, a small toilet room, a large help room with a closet and a separate large general closet. Living quarters are well lighted and stoves are provided for use in the colder months, proper connections being made with the chimneys which extend through the west roof on either side of the dormer.

A narrow stairway beside the harness room leads to the second floor. At the top of the stairs is

the first floor are two large bins. The hay mow over the feeding shed runs at right angles to the barn mow, each mow being equipped with a track and hay carrier which terminates at the ends of the buildings over hay doors. A trap door is provided near the bins so that hay may be dropped to the first floor.

The foundation walls are of concrete 12 in. thick at the base and are tapered to 8 in. at the top,

Second Story Plan Showing Feed Bins and Hay Mow—Scale 1/16 In. to the Foot

First Floor Plan of Horse Barn on Edellyn Farm—Scale 1/16 In. to the Foot

a room lighted by the dormer windows, the chimneys running exposed at this point on their way through the roof. The entire second floor houses the hay mow, while directly over the feed room on

the walls extending to a height of 18 in. above grade. Outside walls are 8 in. thick throughout. The alley running the length of the barn is topped off with creosoted blocks, while the floors in the

harness and feed rooms are of concrete. The box stalls have clay floors while those in the single stalls are covered with 2-in. planks. Floor drains are provided where necessary and wastes discharged from the building through 6-in. tile drains.

The construction represents a popular system of plank framing, a type of work which is simple and offers a maximum of mow space, and is economi-

beams of the same material are provided for each set of rafters. Double plates are provided on top of the studding and $\frac{3}{4}$ -in. tie rods strung to the girders. Every fifth rafter is braced with a 2 x 6 on either side of the rafter, 14 ft. lengths being securely nailed to the rafters and studs. At points shown on the sectional drawing of the barn framing the brace is reinforced by short lengths of

Longitudinal Section of the Horse Barn Showing Feed Bins—Scale 1/16 In. to the Foot

Vertical Cross Section of Horse Barn and Partial Elevation of Feeding Shed—Scale 1/16 In. to the Foot

cal in the use of building materials. On top of the concrete walls are double 2 x 6-in. plates, securely bolted in place by half-inch bolts spaced 5 ft. apart. The studding and sills are 2 x 6 in., the latter being doubled. On the first floor are 6 x 6-in. posts at the end of each stall partition, supporting 8 x 12-in. girders, on top of which are 2 x 10-in. floor joists spaced 2 ft. on centers throughout the length of the barn. The rafters are 2 x 6 in. spaced 20 in. on centers and collar

2 x 6's, one piece being inserted between the two 14-ft. lengths and securely nailed to the rafter and main brace. The studs are covered with drop siding and the rafters with regular roof sheathing, the joints of the latter being broken. The hay mow floor is finished with $\frac{7}{8}$ -in. dressed and matched boards.

The cattle-feeding barn is practically the same size as the horse barn and of the same shape, being 32 ft. wide, 81 ft. 4 in. long and 84 ft. high. The

HAY MOW OVER HORSE FEEDING SHED

same type of framing has been adopted as in the horse barn with some exceptions in connection with the material used for structural members. The drawings show an entirely different first-floor plan, windows being provided only on the west side, or front, and the south side of the building.

Practically the entire first floor is of the open-type feed barn, communicating on the east side with a large concrete yard through six large openings without doors. Two sides of the barn are equipped with feed troughs which are filled from the second floor through openings near the walls. The barn communicates with a weighing room which is centrally located and extends to the west of the main building. Between the barn and the weighing room are two sliding doors. The weighing room also has two large hinged doors on its north and south sides and a door of ordinary

dimensions on the west front, where the scale is operated. At the south end of the building off the open shed is a sliding door leading to a section housing two feed rooms and an alley through the silo. The feed room in the southwest corner accommodates three stanchions, the room being well lighted by four windows, two on each wall. A stairway opposite the stanchions leads to the hay mow. Adjacent to the building on its south end is a 180-ton silo built of hollow tile, with a 10,000 gal. tank on top.

The first floor throughout the building is of concrete, the only exception to this rule being in the feed room back of the stanchions where the cattle stand on creosoted blocks. At this point a concrete gulley has been built, 14 in. wide and 6 in. deep and pitched to a floor drain. The floor rests on a 4-in. bed of cinders and the proportions of concrete are 1:3:5, consisting of one part Atlas Portland cement, three parts washed torpedo sand and five parts washed gravel. The footings and walls are of concrete 12 in. thick, the walls being tapered to a height of 18 in. above grade.

The second floor is partially supported by five posts lining the center of the barn and a like number on the east side, which take the place of the wall. The footings for the posts are of concrete, 24 in. square, and rise above grade 18 in. to dimensions of 12 x 12 in. The posts are 8 x 8 in., secured to the footings by $\frac{3}{4}$ -in. dowel pins 6 in. long. On top of the posts and beneath the girders are 8 x 8 x 30 in. caps, the girders being 8 x 12 in. The floor joists are 2 x 10 in. spaced 20 in. on centers. The collar beams, studs, sills, rafters, braces and plates are all 2 x 6 in., the rafters being spaced 24 in. on centers with collar beams for every set of rafters. The second floor is double, with a good grade of paper between, the top flooring con-

CATTLE FEEDING BARN AND SILO WITH PIGGERY SEEN AT EXTREME RIGHT

sisting of $\frac{7}{8}$ -in. dressed and matched material. At the north end of the hay mow is a 5 x 7 ft. hay door opening, the track for the carrier running the length of the barn at the ridge.

For the silo a concrete foundation 6 ft. deep is provided with 24-in. footings, a 12-in. wall being carried 2 ft. above grade and 6-in. tile set in the center of the wall. At the feed alley openings 2 ft. wide are provided to the top of the silo. The silo is 14 ft. in diameter and 44 ft. high to the water tank, the tile exterior continuing to a height of 20 ft. to house a concrete tank 10 ft. in diameter and 16 ft. high. The roof of the tank has a dormer facing south, all of which is shingled.

The floor of the tank is of reinforced concrete throughout. There are four concrete beams, 12 x

The implement and wagon shed is a combination structure designed to accommodate all farm equipment, with the exception of a thrashing machine and wagons, while a section has been reserved for a corn crib. As shown in the picture, the wagon shed is open and built without doors while the machinery shed is equipped with two sliding doors. The building is 76 ft. long, divided into two sheds of equal dimensions, the corn crib occupying a space back of the wagon shed, measuring 6 x 38 ft., and having doors at each end.

Bottom of Water Tank in Silo

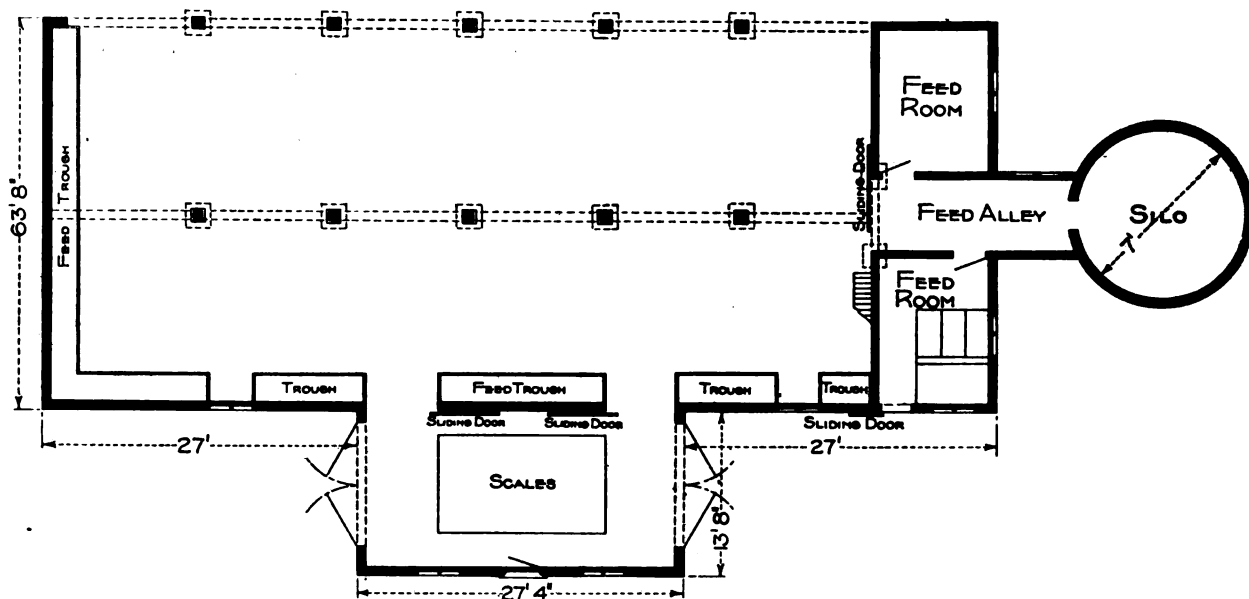

Section of Tank Floor Slab

Detail of Stirrup

Details of Tank Reinforcement

Floor Plan of Cattle Feeding Barn and Silo—Scale 1/16 In. to the Foot

DETAILS OF TANK IN TOP OF SILO AND PLAN OF CATTLE BARN

16 in., and 6-in. floor slabs are reinforced with $\frac{3}{8}$ -in. square twist rods laid 8 in. on centers in both directions. The reinforcing work required $\frac{3}{4}$ -in. twist rods of various lengths, viz., eight 16 ft. 2 in. long, four 14 ft. 1 in. long, four 14 ft. 7 in. long, in addition to 730 lineal feet of rods for stirrups and floor reinforcing work. All rods were bent into shape on the job according to the details shown in the accompanying drawings.

Windows are installed on either side of the building 6 ft. above ground, the dormers being ornamental rather than useful, as they are boarded up.

The shed rests on a concrete foundation and the walls are 2 ft. above grade. The posts at the front of the wagon shed are 8 x 8 in., resting on concrete footings with a 10 x 22 in. base and a 10-in. square top. The posts are topped with 8 x 10 in. caps, the studding 2 x 6 in., placed 2 ft. on

centers and 18 in. on centers in the corn crib. The outside studding of the crib is covered with 1 x 5's beveled, with wire on the cross pieces and the partition covered with 1 x 5's square, with wire on the uprights under the cross pieces. All rafters are 2 by 2 in., placed 2 ft. on centers with 2 x 6-in. collar beams for every rafter.

Particular attention has been paid to the design and construction of the poultry house, in view of the fact that the stock is housed the year around. Here we find an exceptionally fine type of modern building with a south frontage, thus affording a maximum amount of light throughout the day. The proportion of glass surface to wall surface on this side is unusually large, and the provisions are sufficient to light all corners of the building. The poultry house is 16 ft. wide, 48 ft. long and 10 ft.

for cleaning the dropping board. Partitions are provided between the pens and covered with standard poultry netting which is stapled to wooden upright posts.

A feed bin in the alley has six compartments of equal dimensions. The bin is 12 ft. long and 14 in. wide with a hinged cover, each compartment being 14 in. wide, 24 in. long and 24 in. deep.

Each pen has a 40 ft. dirt run with a door at the south end 5 ft. 6 in. high and 3 ft. 9 in. wide, high screens being built between the runs.

The poultry house has concrete footings 12 in. at the base and 8 in. at the top. Foundation walls are 2 ft. above grade and the concrete floor is 6 in. thick. The studs and rafters are 2 x 4-in., spaced 16 in. on centers and covered with 1 x 6-in. boards. Supporting posts are provided down the

REAR VIEW OF CATTLE FEEDING BARN WITH SILO AT THE EXTREME LEFT

6 in. high, arranged with four scratching pens complete with roosts and nests except in the east pen, which is open. A 4-ft. alley runs the length of the building back of the pens and has a door at each end. There are two tiers of sixteen windows, arranged in groups of four to each pen, one tier about 2 ft. above grade and the other above the roof of the pens. Each scratching pen is therefore lighted by four windows covered with poultry netting, muslin screens being also provided to keep out direct drafts. Small doors at the ground level are provided to the runs and between the pens, while there is also a door from the alley to each scratching pen.

There is a total of sixty nests, each pen having two tiers of ten nests. The nests are accessible from the alley for gathering eggs, each group of five nests having a door hinged at the bottom and a catch at the top. On top of the nests are the roosts, which are hinged so that they may be lifted

center of the building of 4 x 4-in. material, resting on 10 x 10-in. concrete footings. The doors at each end of the alley are 1 3/4 in. thick, of four-paneled stock, having dimensions of 3 ft. x 6 ft. 6 in. The feed bin is built of 1 x 6-in. planks, 12 ft. lengths being used for the front of the bin and the hinged cover.

In the construction of the runs, 4 x 4-in. posts are spaced 7 ft. apart the length of the runs and 1 x 4's midway between the posts. The baseboards are 1 x 6 in., securely nailed to every upright, the top members being 2 x 4's in 14 ft. lengths for the sides and 12 ft. lengths for the ends. The entire framework is covered with standard poultry netting, as are the door frames at the end of the runs, the latter being built of 1 1/2 x 2 in. stock, hinged to swing outward.

From the standpoint of construction and lighting, the piggery is practically a duplicate of the poultry house, the difference being in the arrange-

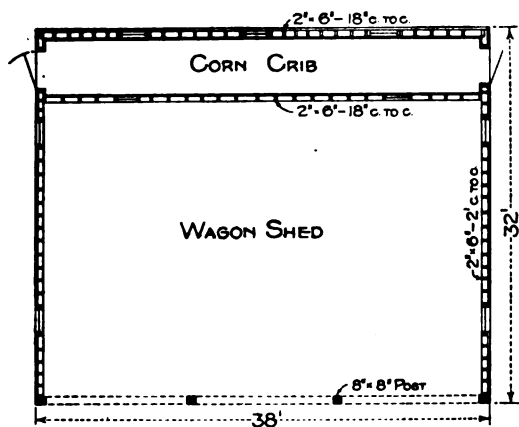

ment of the pens and the windows lighting them. Windows are provided on three sides of the building, the majority on the south side. Each pen has two large windows with six divisions, the end pens being also lighted by the same number of windows on the east and west sides. Above the roof of the pens is a tier of twelve windows in six groups of two. The building is 50 ft. long and about 30 ft. wide, with runs to the south of 60 ft. and a 30 x 60-ft. feed floor on the south-east corner. The lower tier of windows provides for an individual control while the upper tier is

arrangement of the pens is such that either side can be converted into one large pen, or any number up to six, as desired. This feature is made possible by slots in the concrete walls, into which boards are dropped to form partitions. The average pen measures 12 ft. long and approximately 9 ft. wide, so four 12-in. boards laid edge to edge in the slots are sufficient to make a 4-ft. partition. Each pen has a 27 x 32-in. hinged door off the aisle, opening inward, so that the pigs cannot get out.

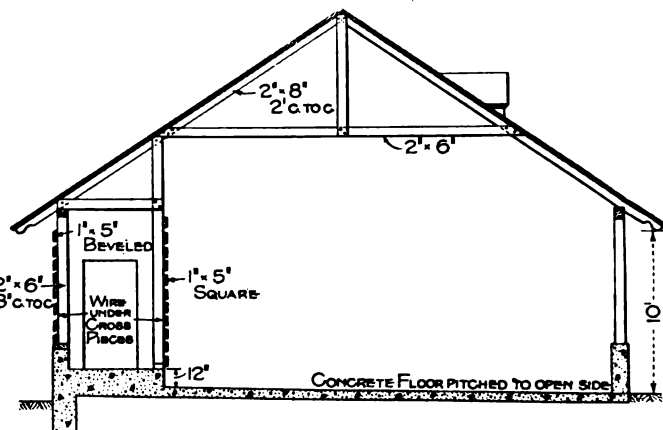

The floors of the pens are half concrete and half creosoted blocks, the

to a height of approximately 4 ft., with slots to accommodate the planks for pen partitions.

The garage is 25 ft. wide and 45 ft. long, well lighted on all sides and also by dormer windows. The building has a capacity to hold two or three automobiles, leaving plenty of room for a large tool box, barrels of oil, a forge and anvil, with enough space to move around in to repair the cars whenever necessary. The garage has two sliding doors with an ordinary door between. The foundation is of concrete 2 ft. above grade and the floor is of concrete, pitched to a floor drain.

End and Side Views of the Piggery

The pump house is 9 x 15 ft. in plan and the creamery 12 x 20 ft., the former housing a deep well power pump connected to a 2-hp. motor, the latter being large enough to take care of an ice-

Plan of Piggery—Scale 1/16 In. to the Foot

box, enameled iron sink, cream separator and churn, all of which are conveniently arranged around the sides of the building, leaving an open space to move around. The building has a concrete floor, is equipped with running water and a floor drain.

The buildings described here-with contain a variety of modern equipment to facilitate operations on the farm. The stanchions are of a type made by the Loudon Machinery Company, Fairfield, Iowa; the hangers for sliding doors by the Richards-Wilcox Mfg. Company, Aurora, Ill.; the tile for the silo by J. M. Preston, Lansing, Mich.; power pump by the Deming Company, Salem, Ohio; two horsepower electric motor by the Wagner Electric Mfg. Company, St. Louis, and the piggery cauldron by Gohmann Bros. & Kahler Company, New Albany, Ind.

The farm is owned by Thomas E. Wilson, Edellyn Farm, Waukegan, Ill., and was constructed under his personal supervision and that of Mr. Dickson, his superintendent, with the collaboration of Mr. Pirot of Morris & Company, Chicago, Ill.

USING HYDRATED LIME IN CONCRETE

The effectiveness with which hydrated lime acts as a waterproofing material is well known, but it is not so generally recog-

nized that hydrated lime introduces other characteristics into concrete that result in rendering it of first quality. It is well known that when hydrated lime is used in cement mortar, says a correspondent, the mortar can be more easily worked under the trowel and better bearing surfaces for the bricks can be made. Add a small amount of hydrated lime to concrete and the same thing happens; the concrete become closely compacted, and the result is a uniform, dense, waterproof piece of work. Concrete containing hydrated lime will flow freely through the chutes or spouts, or out of barrows without the use of excessive quantities of water, and at the same time the use of hydrated lime will be the means of keeping the strength of concrete more nearly normal.

The added plasticity which hydrated lime gives to concrete is the basis of the advantages to be derived from its use. Ten pounds of hydrate to each bag of cement used in a batch is the recommended quantity. An ordinary eight-quart pail holds approximately ten pounds of hydrated lime so that accurate measurements may be made. These are all demonstrated actions of hydrated lime, and should excite the attention of everyone doing concrete work to the possibilities which hydrated lime offers.

SOME SIDE LIGHTS ON WOOD FINISHING

GRADES OF SANDPAPER—FILLERS AND THEIR APPLICATION IN NATURAL FINISH AND COLORS

IT would be interesting to know just when or how sandpaper was invented and who was the first to think of it. Such a simple thing—just a scrap of paper and some glue and sand on it. Who could not have thought of that? But like many another simple invention, it was left to some reflective person to first think it out. Sandpaper does not occupy the office it once did, of course, for it is no longer chief scratcher, steel wool having taken its place—in a measure only, however, as for many purposes sandpaper or glass paper still holds good as the best.

USE OF SANDPAPER

Quite a little essay might be written about the homely but useful sandpaper; and it would be useful reading, too. Following it up in its various degrees of fineness or coarseness, as the case may be, from 000 to 4 (as a neat sample tablet before me gives the numbers), we see the different kinds of work it will do; the finest smooth enough to polish a lady's finger nails, the coarsest rough enough to serve as a section of turnpike road.

But what I started out to tell about was the using of sandpaper. There is a sandpapering machine that makes a surface something wonderful to behold, for it makes circular tracks, and these are not always smooth. It does pretty well for hard, close-grained woods, but on soft, open-grained woods the fine fibers rubbed off by the sandpaper are forced into the open pores of the wood and cause trouble in the finishing. Hence an open-pore or open-grained wood that has been through the sanding machine should be rubbed across the grain with No. 1 sandpaper, after which it should be well dusted off, to remove all loose fibers of wood. This before filling wood for the usual finish.

Many persons do not know that there is a right and wrong way to cut a sheet of sandpaper in two. The right way is to fold it evenly with the sanded part inside, which will prevent cracking or uneven folding. Then cut with a table knife or painter's putty knife, pulling the blade against the paper.

FOR SMOOTHING LARGE SURFACES

For sanding off some surfaces, say those which are large and level, it is best to use a block of softwood, about $2\frac{1}{2} \times 3\frac{1}{2}$ in. To one side of the block glue a piece of rubber belting or sheet rubber of some sort, and when the glue has become dry saw the block into a series of slits, about $\frac{3}{16}$ in. apart and to within about $\frac{1}{8}$ in. of the rubber. The purpose of these slits is to make the block flexible,

which will enable it to fit into a concaved or other shaped surface. Another and similar block may be made solid, for sandpapering large, even surfaces.

Fine as the finest numbers of sandpapers are, yet they are not quite the thing for some kinds of work—such as would be marred by fine scratches and yet must be smoothed down. In such cases it is customary to use fine sandpaper that has been worn down by use until very little sand is left. Another way, thought by many workmen to be better than the worn paper, is that prepared by rubbing two sheets of fine sandpaper together, which removes all of the grit, leaving only the finest particles of sand. A little raw linseed oil is then applied to the face of the paper, on the sanded side, which makes all scratching that would show, impossible. Of course there is scratching, without which the sandpapering would be useless, but it is not seen by the naked eye. Sometimes a piece of coarse canvas may be used with satisfactory results. It all depends upon the character of the surface which is to be smoothed down. For rubbing down hardwood filler No. 0 glasspaper is best. Glasspaper is of a better grade than the ordinary sandpaper, which is flint, not mere sand, the flint being crushed and sifted into grades, just as they do with crushed glass. For a still harder paper garnets are crushed.

TESTING SANDPAPER

There are several ways of testing sandpaper for quality, but the expert workman knows almost by looking at it what it is. Good quality sandpaper will split in two, this sometimes being done in order to get a thin sheet to work in moldings, etc. A poor-grade paper will not split this way. It is not necessary to tell the reader that a good grade of sandpaper is the cheapest in the end.

To prevent sandpaper from slipping under the hand, chalk it on the back. The application of a little benzine or turpentine on the sand part will cause the paper to cut faster. Keep the sandpaper in a dry place; if damp, dry it before using it. Always dampen sandpaper with a little benzine or turpentine before using to sand white lead paint. Save partly worn pieces, for delicate rubbing.

Sandpaper the raw wood with the grain only, to avoid scratches. It is perhaps best always to sandpaper filled wood with the grain. Scratches are difficult to remove, and add to the expense. The fuzz raised on the wood by staining is easier to remove just after the filling than at any other time. All liquid-filled wood should be made smooth with sandpaper before varnishing.

So much for sandpaper, though I might fill out this article with the subject and still not be done.

*A. Ashmun Kelly in the *Wood-Worker*.

Now I shall say a few things concerning the work of wood-filling, giving some notes on fillers and their use. If you make your own filler, see that the silix is dry; if not dry, place it in the oven.

As between thick and thin paste fillers, I say thin. Thick filler will do well only on very coarse wood. Usually it will make rough work and require a lot of rubbing down. It might be well to take a middle course, neither too thick nor too thin. Two thin coats are better than one heavy coat of filler. In fact, the two thin coats are nearly always preferable; it is, however, a matter of expense of time. Such two coats of filler ought to be applied at an interval of not less than twelve hours. Then the filling ought to have at least twenty-four hours for drying before varnishing, although twelve hours will do in a pinch. After you have filled the wood, wait until the stuff turns dark-looking, or grayish, then wipe it off across the grain of the wood. Usually it requires about twenty minutes for the filler to set enough for the rubbing off. A shop rule is from 10 to 14 lbs. of paste filler to the gallon of thinner.

A GOOD PASTE FILLER

A good paste filler will fulfil these conditions: Fill the wood completely; not be easily affected by moisture or any atmospheric influences; unite readily with the wood; remain firm as long as the wood endures intact; be translucent, so as to show up the color and texture of the wood; be simple, cheap and easily applied, and never shrink or swell and thus affect the wood.

Whiting and china clay, often used in fillers, will not fulfill these conditions—nor cornstarch—all being too opaque, hiding the beauty of the wood. Umber and sienna are not positively bad, but they will not do on light-colored woods, nor do they develop the grain on any wood. Too much oil is bad in a filler, causing shrinkage of the filler and a falling away in time, causing a marred surface. Pulverized silica is the very best substance for making the base of a paste filler. When pure it is perfectly translucent. It may be ground to an impalpable powder and still retain its crystalline formation. These crystals fit into the pores of the wood and stay there. Silica has also an affinity for oil and other essential thinners, these being necessary for its application and drying hard.

NATURAL WOOD FINISHING

For natural wood finishing, where the color of the wood must not be altered any more than may be unavoidable, no pigment is used, and for this reason such filler is the best, as coloring weakens it according to the amount incorporated. Some fillers contain as much as 25 per cent of color, necessary for some woods, and this makes a filler that will not fill the pores properly. The colors generally employed for coloring fillers are as follows: For light oak, raw sienna or ochre; dark oak, burnt umber or drop-black, or both combined; golden oak, burnt umber or asphaltum, the latter giving the best color effect, but being less desirable for the reason that it acts badly under varnish; walnut, burnt umber enriched with a little Venetian red or

rose pink. Black walnut is best filled with paste filler colored with Vandyke brown; mahogany, burnt Italian sienna, rose pink and a little drop-black; redwood, burnt sienna and a touch of rose pink; Brazil wood, rose pink; cherry, burnt sienna or Venetian red.

A good formula for making a natural color paste filler for coarse woods, such as ash, butternut, chestnut, elm and the oaks, is: Mix together two parts of pale linseed oil, three parts of japan gold size and one part of turpentine, adding pulverized silica to form the paste. Make a thick paste and thin it down when about to use.

SHELLAC AS A SURFACER

Shellac does as a surfacer for birch, beech, cypress, maple, red gum, sycamore and white pine. In some cases liquid filler may take the place of shellac, being much cheaper. Where shellac is used make it of the strength formed with a pound of gum to the gallon of alcohol. Maple requires the use of bleached or white shellac, owing to its being a very light-colored wood. Orange shellac does for any wood having some color.

A good filler for redwood is made as follows: Cornstarch, 1 lb.; dry burnt Italian sienna, $\frac{1}{4}$ lb.; mix with 1 qt. of turpentine, and add also a tablespoonful of raw linseed oil and brown japan. Mixing is done best in a hand mill, though it may be done all right with a spatula or paddle, taking care to make the mixture perfectly homogeneous. Cornstarch seems to be preferred by those who have much of this wood to fill, although it does not, of course, make as durable a filler. There can be no reason for supposing that silica would not do fully as well.

FILLER FORMULAE

Filler formulas are many, but I have given the standard and best in the one indicated for ash, chestnut, etc. For the oaks we must fill as each kind demands. For an uncolored natural finish mix together one part of raw oil and two parts of turpentine, with japan dryers enough to dry the filler properly. Dark oak requires some coloring, and the filler indicated for ebony may be used, as follows: Make up a paste of dry lampblack or burnt umber and plaster of paris (or silica), mixing to a paste with brown japan or gold size japan. For golden oak filler use the natural paste wood filler, colored with burnt umber and asphaltum. The formula follows: To 10 lb. of uncolored paste filler add 4 oz. of dry burnt Turkey umber and $\frac{1}{2}$ pt. of best asphaltum varnish. Mix to a paste.

The best of liquid hard or softwood filler may be made by thinning down a paste filler, with turpentine or benzine. But if color is to be used it is generally best to use cornstarch, as being of lighter gravity than silica. The heavy silica will settle in the pot; cornstarch will not. This settling or sinking down of the base would leave the color on top, and so, unless the mass were kept constantly stirred, there would be very poor filling. Color would also settle in the pores of the wood, causing uneven color and filling.

VENTILATION OF THE MODERN FARM BARN

DIFFERENT SYSTEMS THAT MAY BE USED —DETAILS OF VALUE TO THE BUILDER

By L. KLIMA

A BARN is ventilated for the purpose of keeping the air fresh at all times during the season when the building must be closed, to take out the excessive moisture, and to keep up the temperature to a comfortable degree during all kinds of weather. This is much easier said than done for in a barn we do not have the advantage of artificial heat, or in most cases, of the use of a propelled fan with which to move the air.

Besides depending upon the heat which is thrown off by the animals which are housed in the building, which varies according to the kinds and sizes, the further problem of humidity in different parts of the country as well as the elevation or altitude is a very important factor in deciding how to ventilate a barn.

FLUE AREA

So far there has been no definite rule which can be established as to the amount of flue area that can be used for each animal due to the fact that it depends entirely upon the climatic conditions of that community.

There are two motive powers which can be utilized in ventilating systems for barns. First is the effect of the wind. Wind, by the pressure on one side of the building may force air into it, and thus drive the air inside out through the ventilating flues, or other openings at some other point.

The suction caused by the wind blowing over the top of the ventilator on the roof will also assist materially in creating a circulation for the air on the inside of the building. In fact, the ventilator on the roof is by far the most important of the three units of ventilation which are the ventilator on the roof, the foul air flues, and the fresh air intakes.

THE SOURCE OF HEAT

The only source of heat in a barn is the animals themselves. For this reason the barn in which the ventilating system is installed must be built in such a way that the greatest possible amount of heat generated by the animals can be retained in the building.

The circulating of the air from the outside to the inside of the building, and from the inside to the outside, does not in any way increase the temperature of it. It has a tendency to decrease the temperature of the barn unless these flues are so arranged that the warm air is trapped in the building.

The walls of the building should be double boarded with matched lumber, with paper between, and all openings between the studding should be closed up tightly. Provisions should be made for closing the

hay chutes, stairway openings and other openings in a ceiling so that the air will not leave at the highest level of the stock room.

Unless the temperature of the room is much higher than the temperature outside, the ventilating system cannot possibly produce its best results.

TYPES OF VENTILATION

There are three types of ventilation for barns which have come to the writer's attention. First and most common is the system of broken windows, loose doors, poorly constructed walls and ceilings, open hay chutes, open stairways, poor floors, and in fact anything that will allow a movement of air through the building. Such a system will keep the air fresh and pure, but fails to keep the stock comfortable. For this reason this system makes the building no better than a shed with a roof over it. The value of the barn has been lost for the reason that it has not been properly constructed to accomplish the results.

The second kind of system is known as the Rutherford System which removes the foul air from the ceiling line and brings the fresh air in at the floor.

There is no doubt but what a system of this kind will remove a great deal of air. It has been a question, however, as to whether it is possible to retain enough heat in the building by this method to keep the room comfortably warm.

As this system has not been used extensively in this country very little can be said for it, but it would not seem possible that a ventilating system which took the warm air from the ceiling out of the building could possibly hold enough of it in the room to make it a comfortable place for the stock.

The third, and perhaps the most successful system known in this country, is the King System of Ventilation originally worked out by the late Prof. F. H. King of the University of Wisconsin, and since that time improved and developed to its present high state of efficiency due no doubt to the fact that it has been commercialized.

SPECIAL DESIGNING

A ventilating system, like a heating plant, must be designed individually for the building into which it goes. The farm papers, and many of the trade papers, have made it appear that ventilating a barn is a very easy matter, while the fact remains that it is a much easier problem to heat a building than it is to ventilate it without the use of fans or artificial heat.

While the King System of Ventilation consists of three principal units, the aerator on the roof, the

foul air flues, and the fresh air intakes, these are only the principal units of the ventilating system just the same as the boiler, radiators, and the pipes are the principal units of a hot water system for a house.

Unless you would have the unions, elbows, valves, and a hundred and one other things which enter into a heating plant, the three principle units could not possibly be made to heat the building.

This is exactly true of a ventilating system for a barn, for it depends largely upon the details of the construction of these three units as to what results can be accomplished in the way of circulation of air through the building.

As there are only three things that produce flesh, bone and milk, and these three things are feed, water and air, you can perhaps more fully realize why ventilation is so important in the modern barn when you understand that it requires the oxygen contained in two pounds of air to properly assimilate each pound of feed and water combined.

Animals will live and produce with a very small percentage of oxygen as compared with what they should really have, but the fact still remains that they will be larger producers, that they will remain in better health, and thus be able to ward off diseases if they receive all the oxygen required.

Preventing the fresh air from entering into a barn has just exactly the same effect on the stock as preventing them from getting enough feed or water. The process in both cases of reducing their vitality is slow, but it is nevertheless very certain.

The animal which receives its full proportion of oxygen in relation to the feed and water is the animal that will be the greatest producer, and be of the stronger constitution. It takes years of breeding and studying to produce a good animal, but it takes only a few months in the ordinary barn without a ventilating system to reduce the vitality of this animal to a point where it is susceptible to all the diseases which are lurking about, and when this time comes, the labor of many years is lost on account of the carelessness in neglecting to furnish the animal with Nature's greatest disinfectant, which is fresh air.

BULLETINS ON FARM BUILDINGS

A. R. Gregg, professor of agricultural engineering, University of Saskatchewan, Canada, in cooperation with Prof. A. M. Shaw and Prof. R. K. Baker of the Animal Husbandry Department of the same institution, and L. B. Beale, British Columbia Forest Service, has prepared a series of ten bulletins on farm buildings. Plans and discussions on planning are given for farm houses, general purpose barns, horse barns, sheep barns, beef cattle barns, dairy barns, ice and milk houses, piggeries, smoke houses, poultry houses, implement sheds, granaries, silos and root cellars. These buildings are designed specially to meet the conditions of Canadian prairies. Each design has been made as simple and economical as possible, in order to meet the needs of the average farmer. Timber construc-

tion is shown in every case, the larger buildings having concrete foundations, and some of them concrete floors. The plans, although printed to a small scale, show sufficient detail that they may be used as working plans.

TENEMENT HOUSE CONSTRUCTION IN NEW JERSEY

A report just issued by Miles W. Beemer, secretary of the Board of Tenement House Supervision of New Jersey, gives a comparative statement of tenement house construction in that state in September, 1916 and 1915, as follows:

Municipalities	September	
	1916 Cost, Estimated	1915 Cost, Estimated
Atlantic City	\$31,000	\$12,000
Bayonne	22,000	15,000
Belleville	5,000
Caldwell	15,000
Clifton	6,000
East Orange	100,000
Edgewater	18,000
Elizabeth	14,000	10,000
Fairview	4,000
Garfield	5,000
Guttenberg	8,000
Harrison	5,000
Irvington	16,000	14,000
Jersey City	224,000	148,000
Kearny	18,000
Lodi	18,000
Montclair	3,000
Newark	119,000	131,000
North Bergen	9,000	16,000
Nutley	26,000
Orange	15,000
Pallade Park	18,000
Passaic	53,000	65,000
Paterson	13,000	41,000
Summit	7,000
West Hoboken	14,000	38,000
West New York	204,000	67,000
West Orange	13,000
Total	\$896,000	\$664,000
Alterations	21,600	15,900
	\$917,600	\$679,900

It will be seen that Jersey City, with \$148,000, and Montclair, with \$3,000, represent the respective extremes.

UNIFORM BUILDING LAWS

It is said that Reading, Pa., will probably adopt the State Building Code, thus saving the expense and trouble consequent to the drafting of a new code. It is suggested that small cities and towns adopt the code of the State in which they are located, as the State experts would probably be better fitted than the local men to draft a code in strict accordance with the best practice. This idea of a uniform code throughout the State is advocated in Massachusetts by the Boston Society of Architects, and its adoption would certainly be beneficial to the best interests of the building trades.

DON'T MIX SAWDUST AND CEMENT

The report which recently circulated through the West that some department of the Iowa State College had recommended the use of sawdust mixed with cement for making concrete floors has been officially denied by Prof. M. F. Costello, head of the Department of Agricultural Engineering, who says: "There is no department of the Iowa State College that would recommend a cement floor made from a mixture of sawdust and concrete."

THE BUILDING TRADES IN LITERATURE

WHAT THE BIBLE, AND SOME WELL-KNOWN WRITERS, HAVE TO SAY REGARDING THE BUILDER

By A. L. H. STREET

FEW occupations have been as much applauded in literature as those of the architect and the builder. Lawyers and doctors have not fared as well in the esteem of authors and poets as have those who are engaged in useful constructive work. God is often typified as the Great Judge, or the Great Physician, but oftener as the Master Builder.

Long before the advent of Christ and Joseph into sacred history, the occupation of the carpenter and of the stone mason had come to be regarded as one of the highest utility to mankind, and of dignity. The Bible witnesses that the members of those trades were looked upon as honest and industrious men, by referring to the building of "sure" and "goodly" houses, and by crediting the builders of Tyre with having "perfected its beauty." The Book vouches for the faithfulness of ancient craftsmen in several places where it is mentioned that great chests of money were "laid out to the carpenters and builders." "Howbeit," reads one passage, "there was no reckoning made with them of the money that was delivered into their hands, because they dealt faithfully."

In other words, in those "good old days," a builder of a church does not seem to have been required to file a mechanic's lien to obtain payment for his services, nor to have been obligated to give a bond to secure performance of his contract. It does appear, however, that there was some danger to workmen other than of being assaulted by strikers, for the Bible speaks of builders working with "swords girded by their sides."

Longfellow thus pays his compliments to the ancient builders:

"In the elder days of Art
Builders wrought with greater care,
Each minute and unseen part,
For the Gods see everywhere."

Coming to modern literature, we find architecture referred to by Schelling as "frozen music." He doubtless deemed it *harmonious* music, but Burns recognizes the fact that there may be an occasional *discord* in building when he says:

"Windows and doors in nameless sculpture drest
With order, symmetry, or taste unblest;
Forms like some bedlam statuary's dream,
The crazed creation of misguided whim."

Carew sees the power of an architect to make a home comfortable:

"Here the architect
Did not with curious skill a pile erect
Of carved marble, touch, or porphyry,
But built a home for hospitality."

The work of builders has been thus glorified by Emerson:

"The hand that rounded Peter's dome,
He builded better than he knew."

And Milton wrote:

"The hasty multitude entered, and the work some praised,
and some the architect: his hand was known in Heaven by
many a tower'd structure high."

Ruskin places architects on a plane with painters and sculptors: "No person who is not a great sculptor or painter *can* be an architect. If he is not a sculptor or painter, he can only be a *builder*."

But all the genius of building is not to be monopolized by man, according to Pope, for he enjoins upon us that we "the arts of building from the bee receive," and Mulock speaks of the makers of a wren's nest as "its merry architects so small."

Just as the clanging of the blacksmith's anvil has been music to the poet's ear, Walt Whitman found music in the plane:

"The carpenter dresses his plank—the tongue of his fore-plane whistles its wild ascending lisp."

The antiquity of the carpenter's disposition to "talk shop," and of his apron and rule is suggested by these lines from Shakespeare:

"He talks of wood; it is some carpenter."
"Speak, what trade art thou?"
"Why, sir, a carpenter."
"Where is thy leather apron and thy rule?
What dost thou with thy best apparel on?"

Humorous reference was made to the trade by Dickens in "Martin Chuzzlewit," as follows:

"A man who could build a church, as one may say, by squinting at a sheet of paper."

CONVENTION OF THE MICHIGAN BUILDERS' EXCHANGE

The Associated Builders' Exchange of Michigan will hold its fourth annual convention in Lansing on Nov. 14 and 15. It is expected that many of the leading builders and contractors of the eight cities composing the membership of the exchange will gather on those dates. The exchange committee comprises President C. S. Wilcox of Lansing, Secretary Charles A. Brown of Detroit and Associate Secretary R. K. Orr of Lansing.

PLANS FOR TEACHERS' COTTAGES

R. S. Kellogg, in co-operation with the U. S. Bureau of Education, has treated the subject of teachers' cottages in a Bulletin that is published by the National Lumber Manufacturers' Association, Chicago, Ill. The rural teacher's problem in the matter of securing living quarters is discussed. The solution offered is the building of a cottage on the school grounds for the accommodation of the teacher or teachers. The Bulletin illustrates five cottages to meet different conditions, together with a number of photographs of buildings of this character in different sections of the country.

A FARM HOUSE OF THE COTTAGE TYPE

AN ATTRACTIVE EXTERIOR COMBINED WITH A COMPACT INTERIOR—DETAILS OF CONSTRUCTION

WE have taken for the subject of one of the two colored supplemental plates which accompany this issue a farm house of the cottage type designed to be placed with its broad front facing the road, the building to have a frontage of 53 ft. 6 in. and a depth of 42 ft. 6 in. The foundation walls are to be of concrete 8 in. thick and supported on footings 10 in. deep extending 6 in. beyond each side of the wall above. The concrete used is to be mixed in the proportions of one part Portland cement to three parts sand and five of broken stones.

All framing timbers are to be of spruce with corner posts 4 x 6 in., plates 4 x 4 in., girders 6 x 8 in., first floor joists 2 x 10 in., second floor joists, 2 x 8 in. and second floor ceiling beams 2 x 6 in., all placed 16 in. on centers and strengthened with 2 x 2-in. cross bridging spaced 6 ft. apart. The studs are to be 2 x 4 in. spaced 16 in. on centers, doubled at all openings and stiffened with one row of cross-bridging. The rafters are to be 2 x 8 in. and 2 x 6 in. spaced 20 in. on centers. The porch floor beams are to be 2 x 8 in. and also spaced 20 in. on centers.

THE EXTERIOR FRAME

The exterior frame of the building is to be covered with 1 x 9-in. hemlock sheathing laid diagonally over which is to be placed a layer of three-ply building paper. Upon this are to be fastened 1 x 2 in. furring strips placed 16 in. on centers and to which metal lath to carry the stucco is to be stapled.

The exterior stucco is to consist of two coats, the scratch coat is to be at least a half inch thick outside of the lath surface and is to consist of one part Portland cement, three parts sand and not more than 10 per cent lime putty. The first coat is to be applied under pressure and must be well scratched before it sets. The finishing coat is to be a quarter inch thick and is to be mixed in the proportions of one part cement to two parts clear sharp sand and three parts of pebbles for rough finish. The stucco is to be given a cream tint.

The roof is to be covered with white pine shingles exposed 5½ in. to the weather and are to be dipped in shingle stain at least two-thirds their length before being laid.

The floors of the rooms in the first story are to be double, the sub-flooring to consist of ¾ x 6 in. tongued and grooved hemlock, while the finish floor in the living room is to be of ¾ x 2½ in. comb grained North Carolina pine. All other rooms are to have ¾ x 4 in. North Carolina pine flooring. The attic floor is to be single and of ¾ x 6 in. pine. The floors throughout are to be brought to a smooth finish, filled and varnished, the living room receiving an additional coat of wax.

All rooms are to be plastered with a smooth hard

finish except the living room, which is to have a sand finish.

The trim for the living room is to be of birch, that of all bed rooms cypress, while the kitchen and wash room are to be trimmed with white wood. All doors are to be of cypress. The trim in the kitchen and wash room is to be enameled three coats of white; all bed room trim is to be finished natural, and the living room trim is to be stained a deep brown and should be brought to a smooth flat finish.

THE CHIMNEYS

The chimneys which take care of the furnace and kitchen range are to be built of brick laid up in a good cement mortar and lined with vitrified flue lining. They are to be supported on concrete foundations, and where the chimneys are exposed above the roof they are to be covered with stucco.

Under the entire building, with the exception of the porch and office, is a large basement to contain a furnace room and a laundry together with a large space for the storage of fruits and vegetables.

A good system of plumbing is to be installed with simple inexpensive fixtures. The kitchen is to be fitted with an iron enameled sink and a forty-gallon galvanized iron boiler over the range. In the laundry is to be a gas range and three-part earthenware wash trays. All the plumbing is to be exposed and all rough pipes are to be painted with an enameled paint. The plumbing in the bath rooms is to be of the open type, the bath tub to be iron enameled, the water closet to have a china bowl and high tank, and the wash stand to be enameled iron. The exposed pipes are to have a nickel plated finish.

The hardware is to be of a bronze plate finish so as to match the lighting fixtures and radiators. The lighting is to be by means of electricity and gas, and combination lighting fixtures are to be installed. There are to be three drop pendants of three lights each in the living room.

HEATING SYSTEM

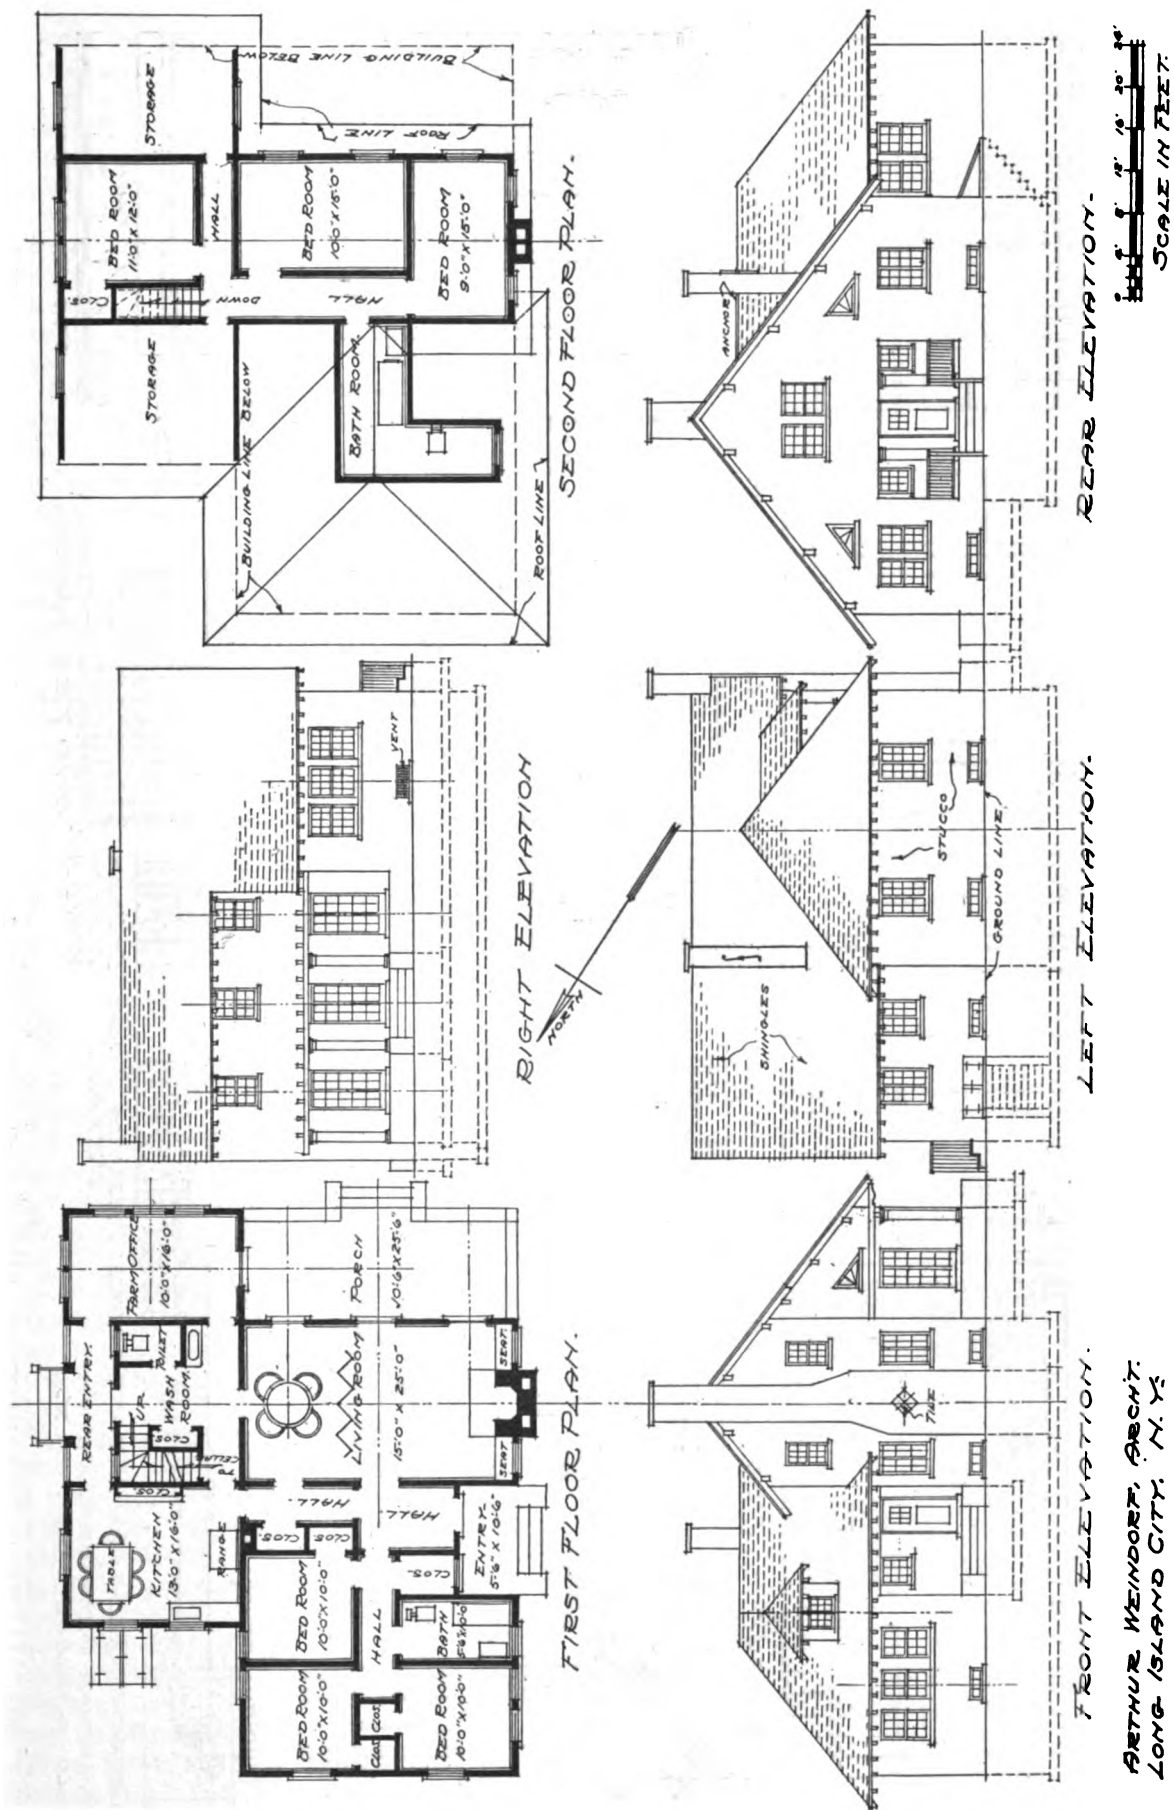

The house is to be heated by steam with radiators of a plain design located in all rooms except the kitchen and to be of such size as to maintain a temperature of 70 deg. in the house when the thermometer registers zero outside.

All exposed exterior trim is to be well puttied and given three coats of white lead and linseed oil. All the sheet metal work is to be painted on both sides before it is laid and all leaders are to be of galvanized iron.

This farm house has been planned with the idea in view of compactness of arrangement while at the same time keeping the living rooms of the family separate and distinct from the rooms which are

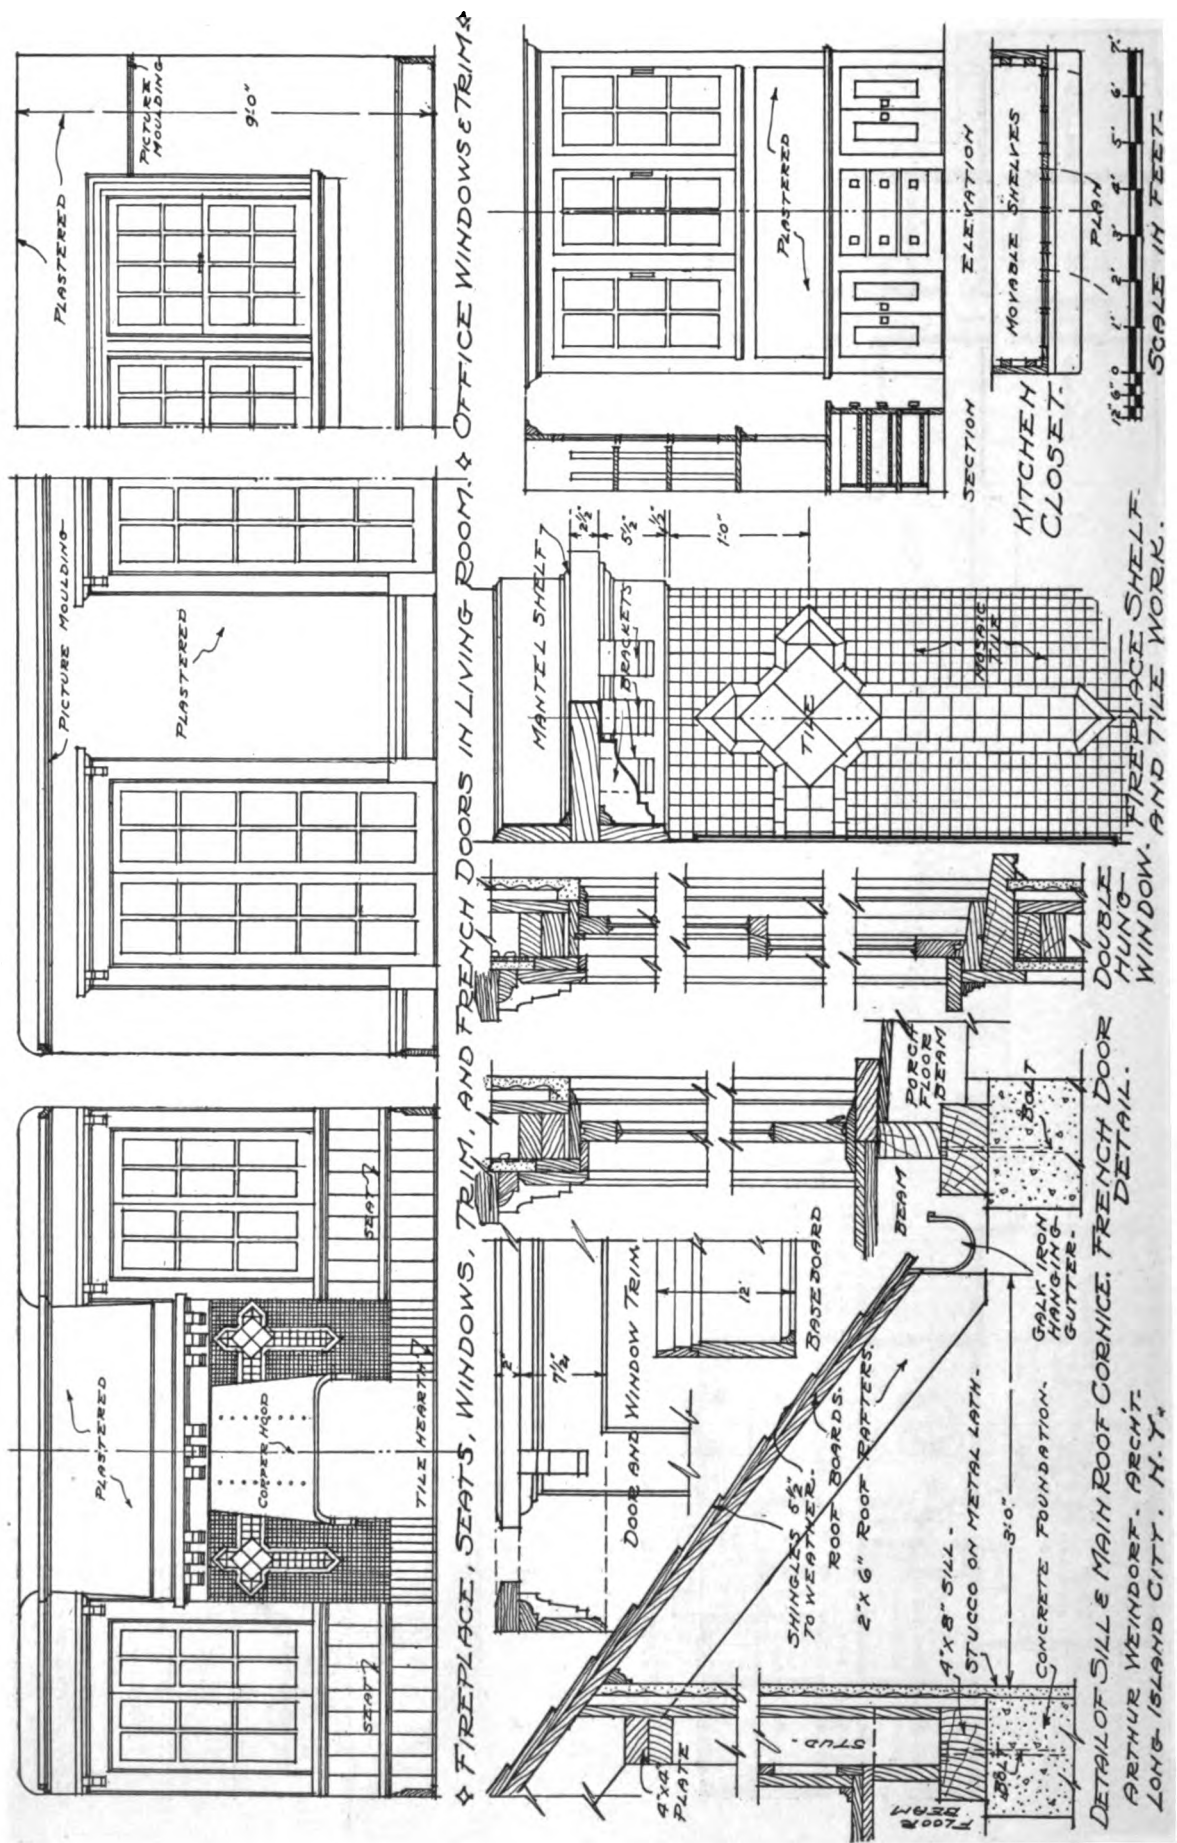

THE COTTAGE TYPE OF FARM HOUSE WITH STUCCO EXTERIOR AND PERGOLA ENTRANCE.

ARTHUR WEINDORT, ARCHT.
LONG ISLAND CITY, N. Y.

PLANS AND ELEVATIONS OF FARM HOUSE OF COTTAGE TYPE SHOWN ON COLORED SUPPLEMENTAL PLATE

MISCELLANEOUS CONSTRUCTIVE DETAILS OF FARM HOUSE OF COTTAGE TYPE SHOWN ON COLORED SUPPLEMENTAL PLATE

used by the hired help. The men coming from the field enter the house by way of the rear porch which leads to a wash room, thus avoiding the necessity of their going into the kitchen and incidentally interfering with cooking operations. The men can go directly from the wash room to their quarters in the attic without passing through any other rooms. The wash room has opening out of it a large closet where the men coming from the field can hang their work clothes. On the opposite side is a toilet. The wash room is connected directly with the kitchen where the men are served with their meals.

The kitchen contains a large combination coal and gas range, a commodious sink and a closet. The dining table for the farm help can be used as a kitchen table upon which to prepare the meals.

The dining portion of the family living room is separated from the rest of it by means of a screen. When all the folks are home for the big dinners at threshing or thanksgiving time, the table can be extended in order to accommodate the members assembled. The porch can also be utilized for dining purposes if necessary, as it is connected with the living room by three large French doors.

The farmer's sleeping quarters and bath are separated from all the other rooms, as may be seen from

an inspection of the floor plans presented herewith. There are three bed rooms and bath with large closet space and a coat closet in the hall. In the attic are located three bed rooms and bath for the farm help and for the servant, also two large storage rooms.

Opening from the rear entrance of the house and overlooking the farm is located the farmer's office. This is connected with the wash room and also opens out on to the main porch. The farmer can see from the windows all of the main buildings and can keep a check on the men as they come and go. The office is intended to be used for the transaction of various farm business and to keep a filing system as well as records of cost, for in these days farming is managed on a scientific basis and the "guessing method" is as useless as it would be in any other business.

The architect states that the cubical content of the house is 44,023 cu. ft., and he estimates the unit cost at 17c. per cubic foot. This, however, does not include the contractor's 10 per cent profit.

The architect of the farm house here illustrated and described is Arthur Weindorf, Long Island City, New York, or care of THE BUILDING AGE, 50 Union Square, New York City.

CAUSES OF EFFLORESCENCE ON MASONRY

METHODS FOR PREVENTING THE TROUBLE —HOW THE DEPOSITS MAY BE REMOVED

By W. C. DUMAS

IT is not uncommon to see an otherwise excellent piece of brickwork or masonry marred by a scum of white efflorescence on the surface. Sometimes these deposits appear in the mortar joints. This is not only unsightly, but in some cases may positively endanger the strength of the work. The cause of these deposits is now fairly well understood, and several methods have been proposed for preventing their formation. The remedy must, however, be applied during the course of manufacture of the brick, or at the time of the mixing of the mortar.

The amounts of the salts which compose these scums vary between 0.001 per cent and 0.50 per cent. As little as one thousandth of 1 per cent can be seen on the surface of a brick. The maximum is about one-half of 1 per cent.

In most cases, these efflorescences are sulphates, but they may be almost any other soluble salt. Lime is the chief offender, and in the majority of cases the greater part of these deposits consists of sulphate of lime. Analysis shows these residues to contain in addition to sulphate of lime, magnesium sulphate, potassium sulphate, sodium sulphate, and aluminum sulphate in lesser proportions.

Why do these salts form in certain cases and in other cases they do not? In the manufacture of brick, the principal materials used are water, clay and coal. All of these materials may contain im-

purities, which contribute to scum formation. The coal may contain a high percentage of sulphur, which during the burning process unites with the insoluble materials of the clay to form soluble salts to a greater or lesser extent. Afterwards, especially if the brick are used where they are exposed continually to moisture, the soluble salts are gradually brought to the surface by the capillary action of the moisture in the interstices and pores of the brick and then deposited on the surface as a scum.

The clays used in the manufacture of brick may contain soluble salts caused in them by weathering. This is often the case, especially if the material has been obtained near the surface where decomposition takes place faster. In the case of clays of this kind, future trouble can be avoided by first leaching out the soluble salts. A more expensive process is to add barium salts to the wet clay before molding.

Some waters used in the manufacture of brick and earthenwares of all kinds carry much dissolved matter which is incorporated with the clay in the mixing. When the raw bricks are dried and burned and the water is evaporated, the chemicals contained in the water are left behind and may prove a troublesome source of scum formation. Such waters should be treated before they are used to remove the objectionable salts.

The drying and burning processes have much to do with the tendency of the product to form scums.

First, the drying must be steady and rapid, and condensation of moisture during this stage must not take place. Afterwards, thorough burning must be had in order to give a hard, compact brick, as well as to cause a partial combination of the soluble salts with the silica of the clay.

The causes and prevention of efflorescence in mortars are the same as those for brick. It is very essential to prevent the formation of scums in mortars because these deposits weaken the material in the mortar joints.

Many patents have been taken out for the prevention of efflorescence on bricks. Some of these patents call for the coating of the outer surface of the wall with some material impervious to water after the bricks are in place. Others of these patents provide various substances which are incorporated in the clays before they are burned. But the surest way to produce a sound product is to control the purity of all materials entering into its manufacture.

Occasionally the cause of the trouble is outside the brick itself. There is a case on record where a certain kind of sand-lime bricks showed a marked efflorescence. Upon examination, it was found that the materials used in the manufacture were free from soluble salts. Finally, the trouble was traced to the storage yards where cinders and ashes had been dumped. The sulphates and other soluble salts from them had been absorbed by the raw brick and were the cause of the trouble.

Efflorescent deposits can be removed from walls without much trouble. If the greater part of the scum is calcium sulphate, a dilute solution of hydrochloric acid consisting of one part of strong acid to five parts of water, will do the work. In certain other cases, the wall is first washed with a solution of hard soap consisting of two pounds of soap to the gallon. After this, it is washed with an alum solution containing one pound to the gallon.

PREVENTING LOSS BY FIRE

Insistence on the proper use of wood, as the best safeguard of the lumber industry, and as the best method of preventing loss and damage by fire is the text of the two latest technical bulletins issued by the engineering bureau of the National Lumber Manufacturers' Association from its Chicago offices. One deals with the general phase of building codes and the other with special problems of chimney, flue, smokepipe and fireplace. The bulletins quote largely from the recommendations of the National Board of Fire Underwriters, and in introducing the technical recommendations, the first one says:

From the standpoint of the lumber industry it is recognized that:

Dwellings are usually the least protected of any class of buildings, and when of flimsy, improper construction constitute an unnecessary hazard.

Wood in such cases is condemned, when actually the fault is not with the material, but with the careless construction and disregard of the fire hazard.

The cost of proper construction in relation to the fire hazard adds only a small percentage to the total cost of the dwelling; yet gives returns in lower insurance rates, and greater safety far in excess of the additional expense.

Intelligent selection of lumber to insure the proper kind and grade for the particular locations or different parts of a structure is essential.

With proper selection should come the consideration of strength of the different kinds of timber. In all cases careful workmanship in framing and placing is necessary.

A consideration of great importance is proper firetops or fire barriers in dwelling house construction. This is one of the actual protective measures which is not as generally known or recognized, but fully as important as safe chimney, smokepipe, and fireplace construction.

Frame dwellings are the most common type, and are not only represented by the millions of existing homes, but will continue to be built in the indefinite future. This is true for both economic and sentimental reasons. Wood remains the least expensive, most universally available, and the most adaptable material. At the same time it responds to architectural treatment in a way which introduces a strong appeal on the ground of beauty and sentiment.

The greatest progress towards fire protection will be made by incorporating in our ordinances and building codes proper safeguards, and by educating the people to the necessity of proper construction. To attempt to legislate wooden buildings out of existence is uneconomical and not the solution. Rather than this, simple and inexpensive safeguards which will not place an unreasonable burden on the builder, should be provided.

The Bulletin on chimneys introduces its safety recommendations with this pertinent phrase:

"It is unfortunately true that the general public which sees and feels the effect rarely appreciates the full importance of the cause. If a fire starts from a defective chimney or flue and burns a wood shingle roof, it would be more logical to pass an ordinance rigidly controlling the construction of flues and chimneys than one prohibiting the use of shingles. Since the burning shingle roof can be seen, legislation is directed against it, and not against the defective chimney which cannot be seen, yet which was the prime reason for the fire."

This Bulletin gives numerous illustrations showing how defective flues cause fires and how flues and chimneys should be constructed, this also being largely based on recommendations of the National Fire Underwriters.

PROPOSED LICENSE FOR BUILDERS

During the past few months several buildings have collapsed while under construction in upper New York City, and the need has been pointed out for some system whereby only capable builders would be lawfully allowed to erect structures. The real estate men of the city, following an analysis by experts of the Advisory Council of Real Estate Interests, are considering means by which this may be effected. The method advocated by Otto M. Eidlitz, the well-known builder, among others, is that "if the builders were licensed, and if the architect was made responsible for the supervision of the plans which he draws, a step would be taken in the right direction."

POLISH ON CONCRETE SURFACES

The amount of polish which can be given to the surface of concrete depends upon the density of the mixture and the nature of the aggregate used. After the surface has been smoothed down on a rubbing bed, or by the use of rotary rubbing stones, as applied in terrazzo floor work, the procedure is somewhat similar to that used in polishing granite or marble, says the *Canadian Engineer*. The aggregate exposed on the surface by the rubbing process takes the polish, the appearance of the surface being dependent upon the percentage of aggregate exposed.

A COMBINATION FARM AND DAIRY BARN

A WELL-PLANNED STRUCTURE INVOLVING MANY
DETAILS OF INTEREST TO THE PRACTICAL BUILDER

THOSE of our readers who are interested in barn construction will doubtless find in the pictures and drawings here presented much to command their careful attention, as the building shown is in the nature of a combination structure for both farm and dairy purposes, consisting as it does of a regular stock barn two stories in height for the stabling of horses and the storage of hay, and a one-story addition arranged especially for cows. It is by no means a large affair, but rather a

extend under the entire area of the stock barn for the reason that it is built on top of a ledge and there is ample space under the cow barn and horse stalls for such purposes as may be necessary.

The practical reader will note in connection with the framing that some of the braces are nailed in place instead of being framed in the usual manner, but from long experience the architects have found that this method is just as satisfactory as the other, for if by any means the braces become loose

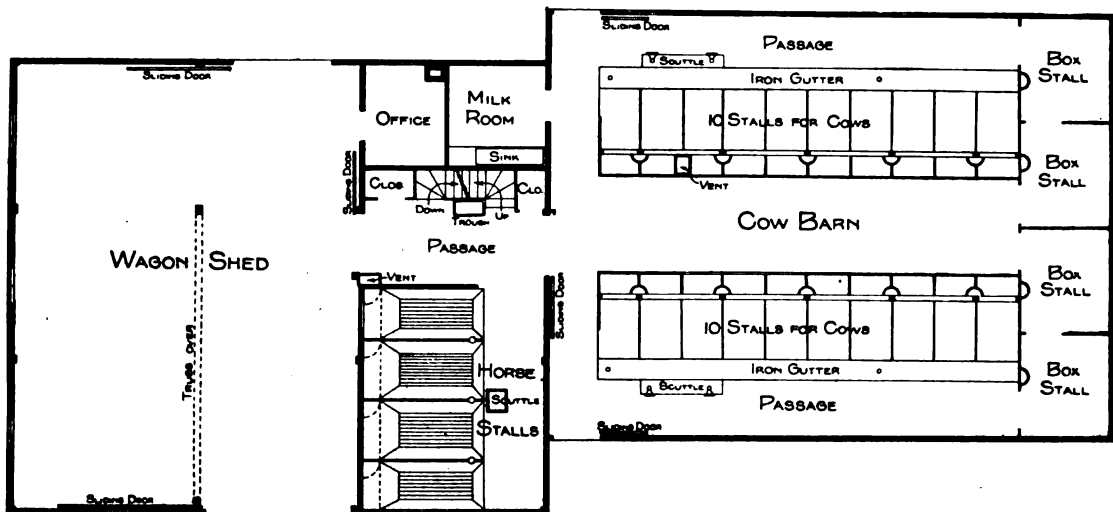

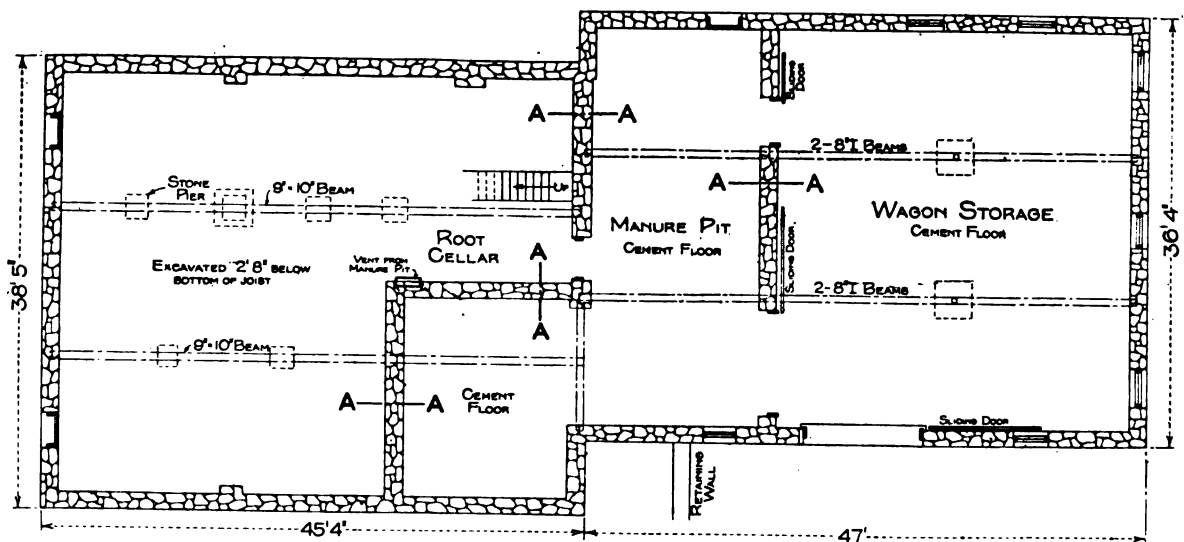

COMBINATION BARN OF LOUIS H. BUCKLEY NEAR WORCESTER, MASS.—ARCHITECTS,
JOHN P. KINGSTON & SON, OF THAT CITY

barn to meet the requirements of the average farmer in many sections of the country and particularly in the eastern and New England States.

The halftone engravings represent front and rear views of the barn, one showing some of the dairy stock in the yard and others the bold effects produced by the use of field stone for the basement walls. The many details afford an excellent idea of the methods of construction.

It is interesting to note that the cellar does not

it is easy to drive them tight in place again. It will also be seen that the braces on the outside walls are placed inside of the studs instead of putting them in first and then cutting the studs over. The architects call attention to the fact that there may be some things about the construction here shown that may not be altogether in accord with the views of the readers, as, for example, nailing in the top ends of the studs instead of a tenon and the method of placing 2-in. plank braces from main

Front or South Elevation of the Barn—Scale $\frac{1}{16}$ In. to the FootFirst Floor Plan Showing Position of Stalls, Wagon Shed, Office, Milk Room, Etc.—Scale $\frac{1}{16}$ In. to the FootFoundation Plan Showing Storage Room for Wagons, Root Cellar, Manure Pit, Etc.—Scale $\frac{1}{16}$ In. to the Foot

PLANS, ELEVATION AND DETAILS OF CONSTRUCTION

plate to the cross braces. As to the first, the architects have long since exploded the idea that there is such an amount of hay pressure on the walls of a barn as to require any unusual strength and that it is much easier to first put up the large timbers of the building and then the studding afterward as can be done in this way. In regard to braces, the architects state that they cannot be put in as usual owing to the fact that the timbers do not come on a line, and in their opinion a much stronger building is obtained by keeping the cross girts below the plate with large tenons in the posts than would be the case if the girts connected with the side of the plate for then the girt and the post

is 3 ft. thick at the bottom and 1 ft. 6 in. at the top. The walls of the cow barn and those surrounding the manure pits above the cellar bottom, as well as the retaining walls, are laid up in cement mortar composed of two parts Portland cement, one part lime and three parts sand. The exposed parts of the walls outside are done with the best field stone having joints pointed up in Portland cement. The top of the retaining wall is covered with Portland cement 2 in. thick.

The cellar has a cement floor consisting of a $2\frac{1}{2}$ in. base of cement concrete and a wearing surface $\frac{3}{4}$ in. thick. The base consists of one part Portland cement, three parts clean coarse sand and

VIEW OF COMBINATION BARN, SHOWING THE FIELD STONE FOUNDATION AND THE RETAINING WALLS

tenon would conflict and one or the other would be so short as to render it of no account. On the other hand, the plank braces if well fitted and fastened in place answer every purpose for a barn of this kind.

The aim of the architects has been to secure a good strong, fairly light-timbered building with as little framing or cutting to pieces of the material as possible and at the same time an easy one for the workmen to put together.

The foundation walls under the stock barn are 2 ft. thick at the bottom, and 1 ft. 6 in. at the top. The walls under the cow barn are 2 ft. thick, resting on a 3-ft. bed stone 6 in. thick. The division walls around the manure pits are also 2 ft. thick at the bottom and 1 ft. 3 in. at the top. The retaining wall outside, and shown in one of the pictures,

is 3 ft. thick at the bottom and 1 ft. 6 in. at the top. The walls of the cow barn and those surrounding the manure pits above the cellar bottom, as well as the retaining walls, are laid up in cement mortar composed of two parts Portland cement, one part lime and three parts sand. The exposed parts of the walls outside are done with the best field stone having joints pointed up in Portland cement. The top of the retaining wall is covered with Portland cement 2 in. thick.

The frame work is of the style usual for such a building, the sills being 6 x 8 in., the first floor girders of the stock barn 9 x 10 in., and the supporting girders under the floors of the cow barn are made of two 8-in. steel I-beams. The first floor joists in the center bay of the stock barn are 3 x 9 in. and in the side bays 2 x 9 in. The two large joists under the stalls are 5 x 9 in., the joists in the cow barn and the second floor joists in the stock barn 2 x 9 in., the outside girts, second floor, 7 x 7 in., and the inside girts 7 x 8 in. The main plates are 6 x 8 in., the purlins 6 x 7 in., all outside studding 2 x 4., and the rafters 2 x 6 in. The cross ties at each post in the cow barn are 2 x 6 in., and the

beam over the horse stall posts measures 4 x 6 in.

The outside posts are full length and have a tenon at the bottom the full width of the timber, 2 in. thick and 2 in. long. There is also a tenon at the top the width of the timber 2 in. thick, 3½ in. long and fastened to the plate with a draw pin. The end posts have a tenon 4½ in. wide, 2 in. thick and 3½ in. long and fastened to the timbers with one draw pin. The inside posts have a tenon 2 in. thick and 2 in. long and set on top of the girders. The top end has a 7 x 2 x 3½ tenon and is fastened to the beam with a draw pin. The outside studs have a 2 x 2 in. tenon at the bottom ends to set into the sills and girts. The top ends are nailed in place.

There is a truss over the openings at right angles to the joists. The latter are bridged once between bearings with 1 x 3 in. stock. Partitions are constructed with 2 x 4 and 2 x 3 in. studding placed 18 in. on centers.

The exterior frame work is covered with matched spruce boards ⅞ x 9¼ in. wide dressed on one side. These are covered with sheathing paper

wide. The milk room and office have a top floor of ⅞-in. spruce not more than 6 in. wide.

The sash are glazed with second quality single thick American sheet glass and are hung with cast-iron weights and Samson sash cord. The sash in the cow barn are 1¼ in. thick, made to slide side-wise. The sash at the top in the monitor roof are 1¼ in. thick hung at the bottom with two hinges, and have proper fixtures and cords to open and close from the floor below.

The sliding doors of the first floor have a jamb made of 2-in. stock and hardwood thresholds 3 in. thick. The large outside doors have a frame of 2-in. stock having chamfered stiles, rails, etc., with ¾-in. sheathing on the back and stationary sash as shown. Doors are hung to slide at the top with approved sliding door hangers. The doors in the cow

Various Details of Floor Construction—Scale ¾ In. to the Foot

End Elevation—Scale 1/16 In. to the Foot

over which are placed 16-in. spruce clapboards exposed 4½ in. to the weather.

The rafters are covered with ⅞ x 9¼-in. matched spruce boards which carry a layer of tarred roofing paper well lapped at all joints. This in turn is covered with 10 x 18 in. sea green slate. The slate on the roof over the doors is 8 x 12 in., each slate being fastened with two 1¼-in. Swedish galvanized iron nails. The ridges have zinc roll. Sides of ventilator are covered with dark slate.

The whole of the first story except the central portion of the stock barn has a lining floor of No. 2 matched ⅞-in. spruce boards. The center portion of the stock barn has a lining floor of No. 2 matched 1⅞-in. spruce boards. The whole of the second story or hay bays in the stock barn has a single floor of No. 2 matched ⅞-in. spruce boards laid as tight as possible to the studs. The top floors in the whole of the first story, except otherwise specified, are of 1⅞-in. square edge planed and jointed spruce flooring not more than 7 in.

barn are 1¼ in. thick with heavy panels and chamfered edges. These are hung at the top so as to slide sidewise.

The ventilator on the main barn is built with ⅞-in. ventilating slats, jambs and casings and has 2-in. stools.

The horse stalls are fitted with W. A. Snow & Co.'s steel stall basins 6 ft. x 2 ft. 6 in., having constructed with the basin resting over the lining heavy slatted floor hinged to lift up. The floor is floor, then there is a second or middle floor of ⅞-in. matched spruce furred up all around the outside 1 in. so as to pitch to the basin. It is tarred all over and has one thickness of one-ply Paroid roofing paper well lapped, and all parts connecting with the basins are filled with elastic cement. The top or finish floor is of 1⅞-in. spruce jointed at the corners, laid close and well nailed.

The cow stall floors are laid with 2-in. furring pieces over and fastened to the joist so as to raise the floor. The under floor is of ⅞ matched

spruce, and the top floor of $1\frac{1}{8}$ -in. square edge spruce. The floor toward the outside has two pieces on top of joist to raise the floor up 3 in. on the outside and 2 in. inside. The lining floor is of $\frac{7}{8}$ -in. spruce and the top floor is of $1\frac{1}{8}$ -in. square edge spruce.

The cow stalls are fitted with swivel wood stanchions and individual drinking basins with running water.

The low space between the stall floors and the portion next to the outside wall has an iron cow stall gutter 18 in. wide by 3 in. deep at the highest part and graded to pitch from each end toward the center about $1\frac{1}{4}$ in. with outlet at that point.

The manger is made with a bottom and front of 2-in. plank, while the feed boxes underneath are of matched spruce boards and have a cleated lid or door hung with fasteners. The stall partitions separate each grain bin. Each stall has an iron hay rack with six $\frac{5}{8}$ -in. iron bars 3 ft. high, put up as shown in the details.

The vent shafts are made with a 2 x 3 in. piece in each corner and then covered outside with matched spruce boards. The vent from the horse manure pit connects through the wall as shown, is then carried straight up to the roof, and over and up to the cupola. The one in the cow barn is carried up to and through the roof about 1 ft. with

FRONT VIEW OF THE BARN OF LOUIS H. BUCKLEY—ARCHITECTS, JOHN P. KINGSTON & SON, WORCESTER, MASS.

The outlets from the iron troughs or gutters are drained through iron soil pipe to the manure pit located under the horse stalls and part of the cow barn cellar. The pit is entirely inclosed with a stone wall, has a cement floor and is ventilated up through the building to the cupola on the roof.

The horse stalls have 6-in. round hard pine posts with grooved portion to receive plank of $1\frac{3}{4}$ -in. spruce, matched and planed. The partitions are 5 ft. high and slant off toward the height of the stalls as shown, with a piece of 2 x 3 in. stuff nailed at the ends. Each side of the plank at the head of the stalls has a $1\frac{1}{8}$ x 2 in. strip to hold it in place. The partitions at the head of the stalls are of 2 x 4 in. studs boarded both sides with spruce boards down to the top of the grain boxes.

wood. The remainder is made of galvanized iron well braced and the top is well fastened to the woodwork so as to give it proper rigidity.

The feed bins in the cow barn are made with a 2-in. plank projecting above the floor at least 8 in., the parting being 2 in. thick.

The partitions around the milk room, the office and the closets are made with 2 x 3 in. studs, while those inclosing the box stalls in the cow barn are built with 2 x 4 in. studs, placed 18 in. on centers, one side being inclosed with matched and planed spruce boards. The partitions are 5 ft. high.

The walls of the partitions at the east side of the center bay, up to the top of the second floor, the walls and ceiling of the horse stall room, passage, office, milk room and all the exposed parts of

BUILDING CONDITIONS ON THE PACIFIC COAST

Our correspondent, writing under date of Oct. 5, says: While official building records in San Francisco are small as compared with a few years ago, there is considerable work going on in the down-town district, and contractors, as a rule, are keeping fairly busy. Prices of materials, especially steel and hardware, plumbing goods, etc., prevent much speculative activity in office buildings or hotels, and last year's preparation for the Exposition crowds left the city with abundant living accommodations. Dwelling work in the suburbs, however, is reviving, with evidence of a reaction from "cliff-dwelling" in down-town apartments. Work

MISCELLANEOUS CONSTRUCTIVE DETAILS

cordance with plans and specifications prepared by architects John P. Kingston & Son, 508 Main Street, Worcester, Mass.

The contractor executing the work was Urgel Dorais, 3 Exeter Street, Worcester, Mass.

"Strength of Webs of I-Beams and Girders" is the title of Bulletin No. 86 of the Engineering Experiment Station, University of Illinois. The matter contained therein has been prepared by Herbert F. Moore and W. M. Wilson, who present much valuable information along the lines indicated.

for large corporations is an important factor, as several are having good-sized office buildings erected for their own use, and many are working on modern manufacturing plants and warehouses either here or across the Bay.

Labor conditions are rather unsettled, and the structural steel shops are, for the most part, running on an "open-shop" basis, their work being greatly hampered. The waterfront trouble is no longer affecting the lumber market, as most lumbermen are handling their cargoes with stevedores furnished by a company in which they are all interested, employing non-union help.

Many corrugated iron warehouses are usually

built through the country in September to house the crops, but this year other materials have been largely substituted, the cost of galvanized iron being almost prohibitive. Bars jobbing at about 4c. per lb., and wire-reinforcing fabric correspondingly high, tend to discourage concrete construction; but it is nevertheless being used quite largely, as fabricated steel is even more expensive. Cement, rock and sand show little fluctuation.

Lumber prices have been comparatively low, but the northern mills made an advance on fir, especially uppers, the first of the month, owing to a marked increase in demand, many mills and yards having less than normal stocks.

An interesting phase of the lumber situation is the heavy demand in South Africa, Australia, South America, etc., which, from lack of ships, is leading Pacific coast lumbermen to build many wooden vessels for this traffic. The type most popular is a five-masted schooner of about 2,000,000 board ft. capacity, with Diesel-engine power. At least half a dozen such vessels are building on San Francisco Bay, and many more than that at Astoria and St. Helens, Ore., and some on Puget Sound. Carpenters who understand marine work are in demand, and those at San Francisco recently received an advance in wages.

This has been a good year for the brick and terracotta industry, the cost of other materials tending to turn the demand in this direction. Common brick has held steady at \$10 per m. on the job in San Francisco, which is higher than a few years ago, but not excessive; and many yards have been running at capacity on large contracts. Texture brick for facing is very popular.

THE CHICAGO CEMENT SHOW

Announcement has been made that the Tenth Annual Cement Show will be held in the Coliseum and Balcony in the city of Chicago, Ill., on Feb. 7 to Feb. 15, inclusive. The concentration of exhibits in the Coliseum balcony and annex will enable visitors to conveniently make inspection of them, while at the same time machines and products will be closer together, thus facilitating comparison and enabling prospective purchasers to make their selections more expeditiously.

It is now expected that there will be a joint exhibit of cement companies similar to the one at the show early this year. This last exhibit was regarded by visitors as the most complete and comprehensive display of the uses of concrete ever presented to the public. It is, however, planned to make the coming exhibition even more comprehensive and to show to as large an extent as possible products in the making.

During the eight-day period, Chicago will be the center of activity in the building material industry. The National Builders' Supply Association will hold its annual convention at the Hotel Sherman, Feb. 11 and 12, and the Illinois Lumber & Builders Supply Dealers' Association at the same hotel, Feb. 13 and 14. It is also likely that the American Concrete Institute will meet during the progress

of the show, also the American Pipe & Tile Association and possibly the American Association of Engineers.

It is pointed out by the management of the Cement Show that closing the affair on a Thursday will make it unnecessary for the exhibitors to be away from home more than one Sunday. Since only the Coliseum and Annex will be used for display purposes it is probable the demand will exceed the available space and it is suggested that those desiring to exhibit should make early application for space.

CORRESPONDENCE COURSE IN LUMBER AND ITS USES

Architects, teachers of manual training, lumbermen and manufacturers of wooden materials are taking advantage of the correspondence course in Lumber and Its Uses, offered by the Department of Forest Utilization in the New York State College of Forestry at Syracuse. So many of our valuable woods, which were so plentiful up to ten or fifteen years ago, are rapidly being depleted, and so many new woods of both native and foreign origin are coming into our markets that it is becoming necessary to become acquainted with these new woods, together with their character, technical qualities and uses. The college announces a course in Lumber and Its Uses and Wood Utilization, to be held next winter in the new College of Forestry Building at Syracuse University.

LAUREL FOR INTERIOR FINISH

California laurel, suitable for interior finish, is now being placed on the market in considerable quantities, as some large tracts of this timber have been opened up by the new railroad into Humboldt County. It is at present offered in San Francisco at \$60 per M ft., about the same as clear Oregon pine finish, and much cheaper than other hardwoods, which makes it very attractive to the builder, writes our San Francisco correspondent.

The laurel lumber, when properly cured, is very hard, firm and fine-grained, of a rich yellowish-brown color, sometimes beautifully mottled. It is especially good for staining to imitate mahogany and is finished in that color in many homes now being built.

Dimension timber of laurel is being used for keel blocks in the new Union Iron Works drydock, owing to its ability to stand great pressure without splintering.

HEAVY DEMAND FOR BARN MATERIALS

Lumber dealers doing business in the vicinity of Carlisle, Ky., report the demand for barn material to have been the heaviest for years, and carpenters say that more barns are being erected in that county than for several seasons. All new barns are being rushed to completion to take care of the tobacco crop.

MODERN FARM BUILDINGS UNDER ONE ROOF

AN EXTERIOR FINISHED IN STUCCO WITH
THE INTERIOR COMPACTLY ARRANGED

THE subject of the accompanying colored supplemental plate is a barn which has been designed with a view to keeping under one roof the various buildings which are usually scattered over a considerable area, and which are separate and distinct. This arrangement of combining all the buildings in one will save many steps that are usually spent in going from one structure to another, and at the same time it puts all the buildings under easy control. The cost of construction is reduced, as some of the usually required outside walls are not necessary, and there is also a saving in plumbing, lighting and foundation walls.

ARRANGEMENT OF BUILDINGS

This farm building has been arranged to provide sufficient space for fourteen cows, two calf pens, one bull pen, feed room for mixing feed, a 12-ft. silo, stalls for five horses, two box stalls, harness room, feed room for horses, two hay mows, a wagon room, garage, farm implement room in which space is set aside for a water-power plant, gasoline engine and dynamo to generate electricity to drive the stationary farm machinery.

The attic, which is located over the wagon room, garage and implement room, contains three large bed rooms and bath, designed to be used for the farm help.

At the rear of the barn and connected with it is a large poultry house with brooding and roosting rooms, while at the other end of the barn is an ice house and milk room.

The architect points out that the farm building has practically a fireproof exterior and partially fireproof interior, while the garage is of fireproof construction. The foundation walls and the entire floor of the building are to be of concrete mixed in the proportions of one part Portland cement to three parts sand and five of broken stones. The foundation walls are to be 12 in. thick and rest on footings 10 in. thick extending 6 in. on either side of the walls above. The foundation walls should be carried down below the frost line so as to avoid all danger in this respect.

THE FRAMING TIMBERS

The entire framing timbers are to be of spruce, the floor joists to be 2 x 12 in., the studding 2 x 6 in., the wall plates to consist of two pieces of 2 x 6 in., the upper and lower roof rafters 2 x 6 in., braces 1 x 8 in. and 2 x 6 in., and cleats 1 x 8 in. The studs, rafters and joists are to be spaced 24 in. on centers.

The side walls of the building, as well as the entire roof are to be covered with hemlock sheathing boards, over which is to be laid a waterproof building paper. Over the building paper on the exterior walls 1 x 2-in. furring strips are to be nailed 13 in. on centers, and these in turn are to be

covered with composite metal lath, upon which the stucco is to be applied. On the interior the lath is to be applied directly to the under side of the floor joists and studding and given a smooth stucco finish which will enable the interior of the barn to be washed out with a hose. The roof is to be covered with asbestos shingles.

THE CONCRETE FLOOR

The floor is to be of concrete, 6 in. thick, and should be 6 in. or 8 in. above grade outside. The floor should never be lower than the ground level at the door, as it is better to have the live stock step up rather than down to the floor level, as in the latter case there is great chance of live stock slipping, especially when stepping down over a door sill onto a smooth concrete floor at a lower level.

A concrete approach with a ribbed surface should be constructed on the outside of the barn leading from the ground level up to the floor level, as this will prevent the live stock from stumbling and tracking much dirt. The stalls are to have a 4-in. wood block floor laid on 2 in. of sand, which is intended to act as a cushion.

The floor of the hay mow is to be of 1 x 9-in. matched and dressed pine.

The doors are to be built up of matched flooring and made double thick, with two thicknesses running at right angles to each other, so as to prevent warping. The building paper is to be placed between the two thicknesses, which will tend to make it an insulated surface. All doors are to be hung on extra strong hinges, and are to be provided with automatically fastening devices. All glazed doors are to be protected by a heavy wire mesh.

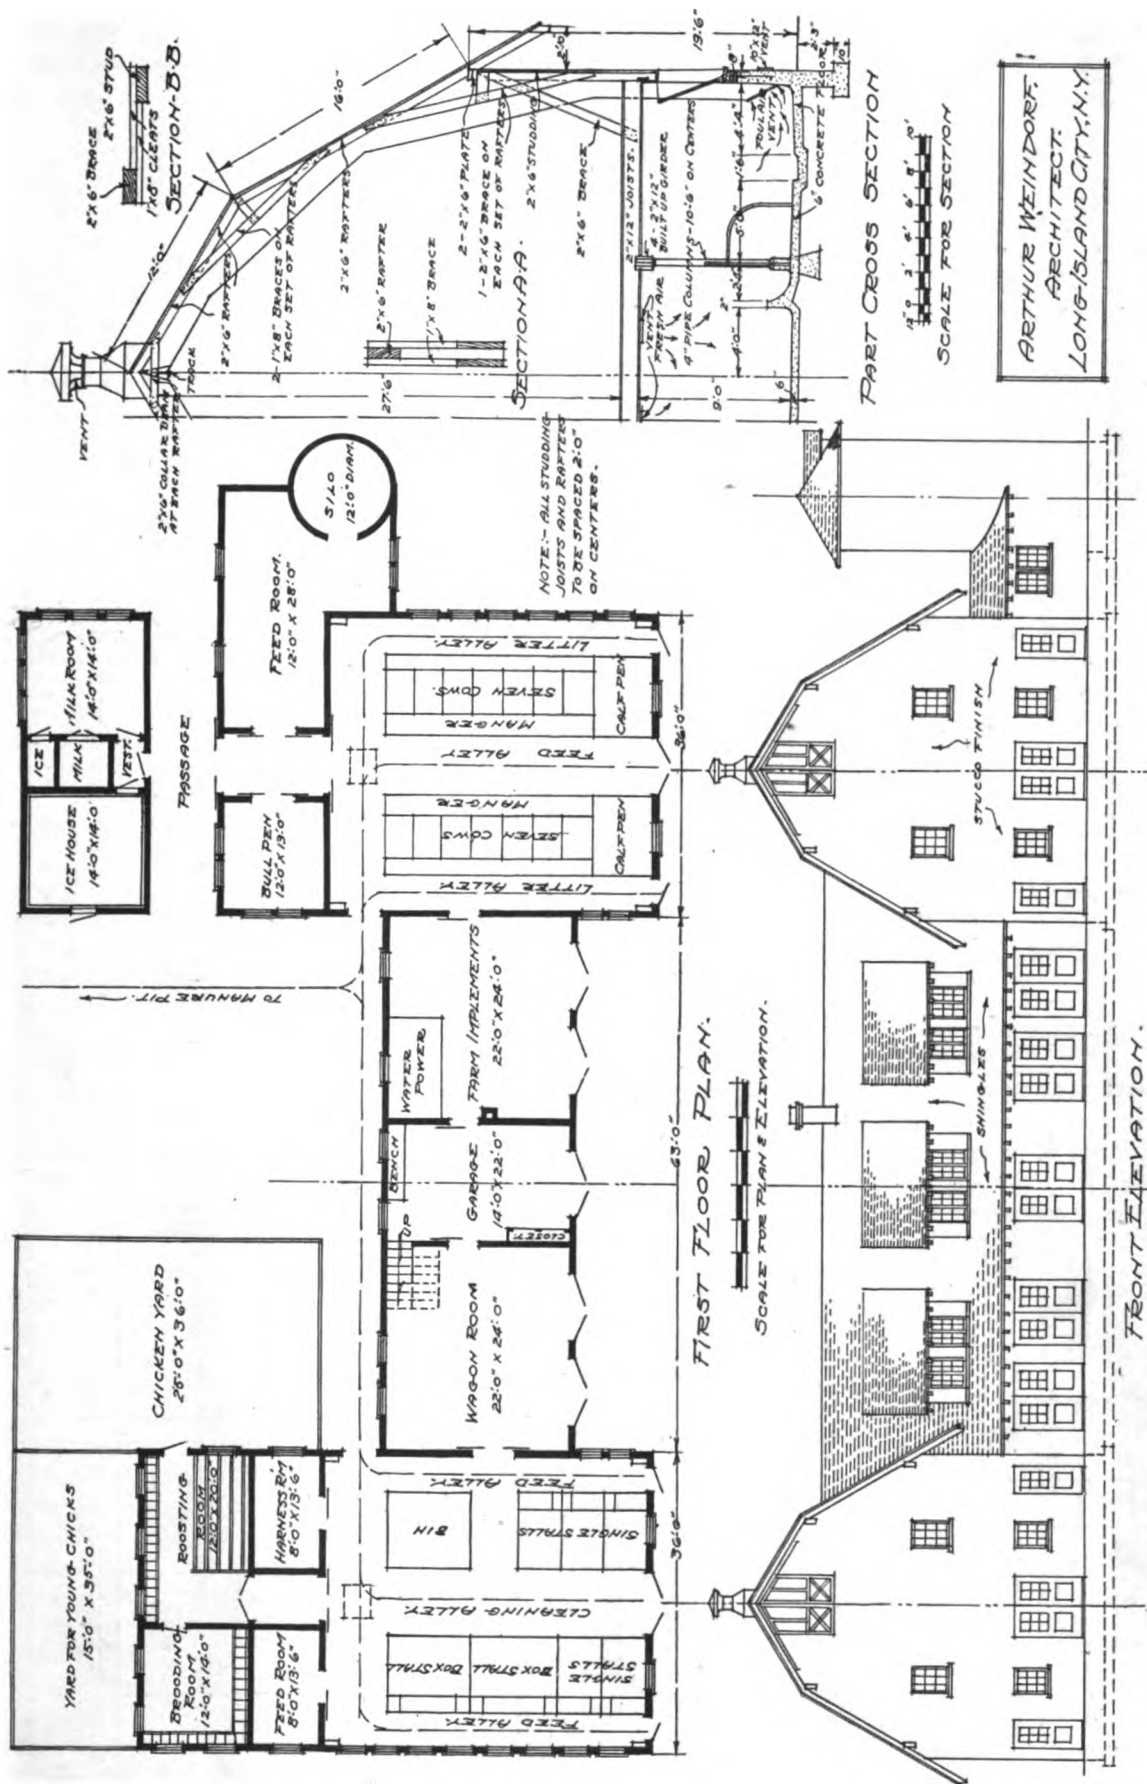

THE PROPER VENTILATION

The proper ventilation of the barn is very important from the standpoint of the health of the live stock. In this case, where the live stock face in, the fresh air flues are placed in the side walls of the building, starting just high enough from the ground on the exterior to prevent the snow from closing them up. The openings are also protected with wire mesh to keep out birds.

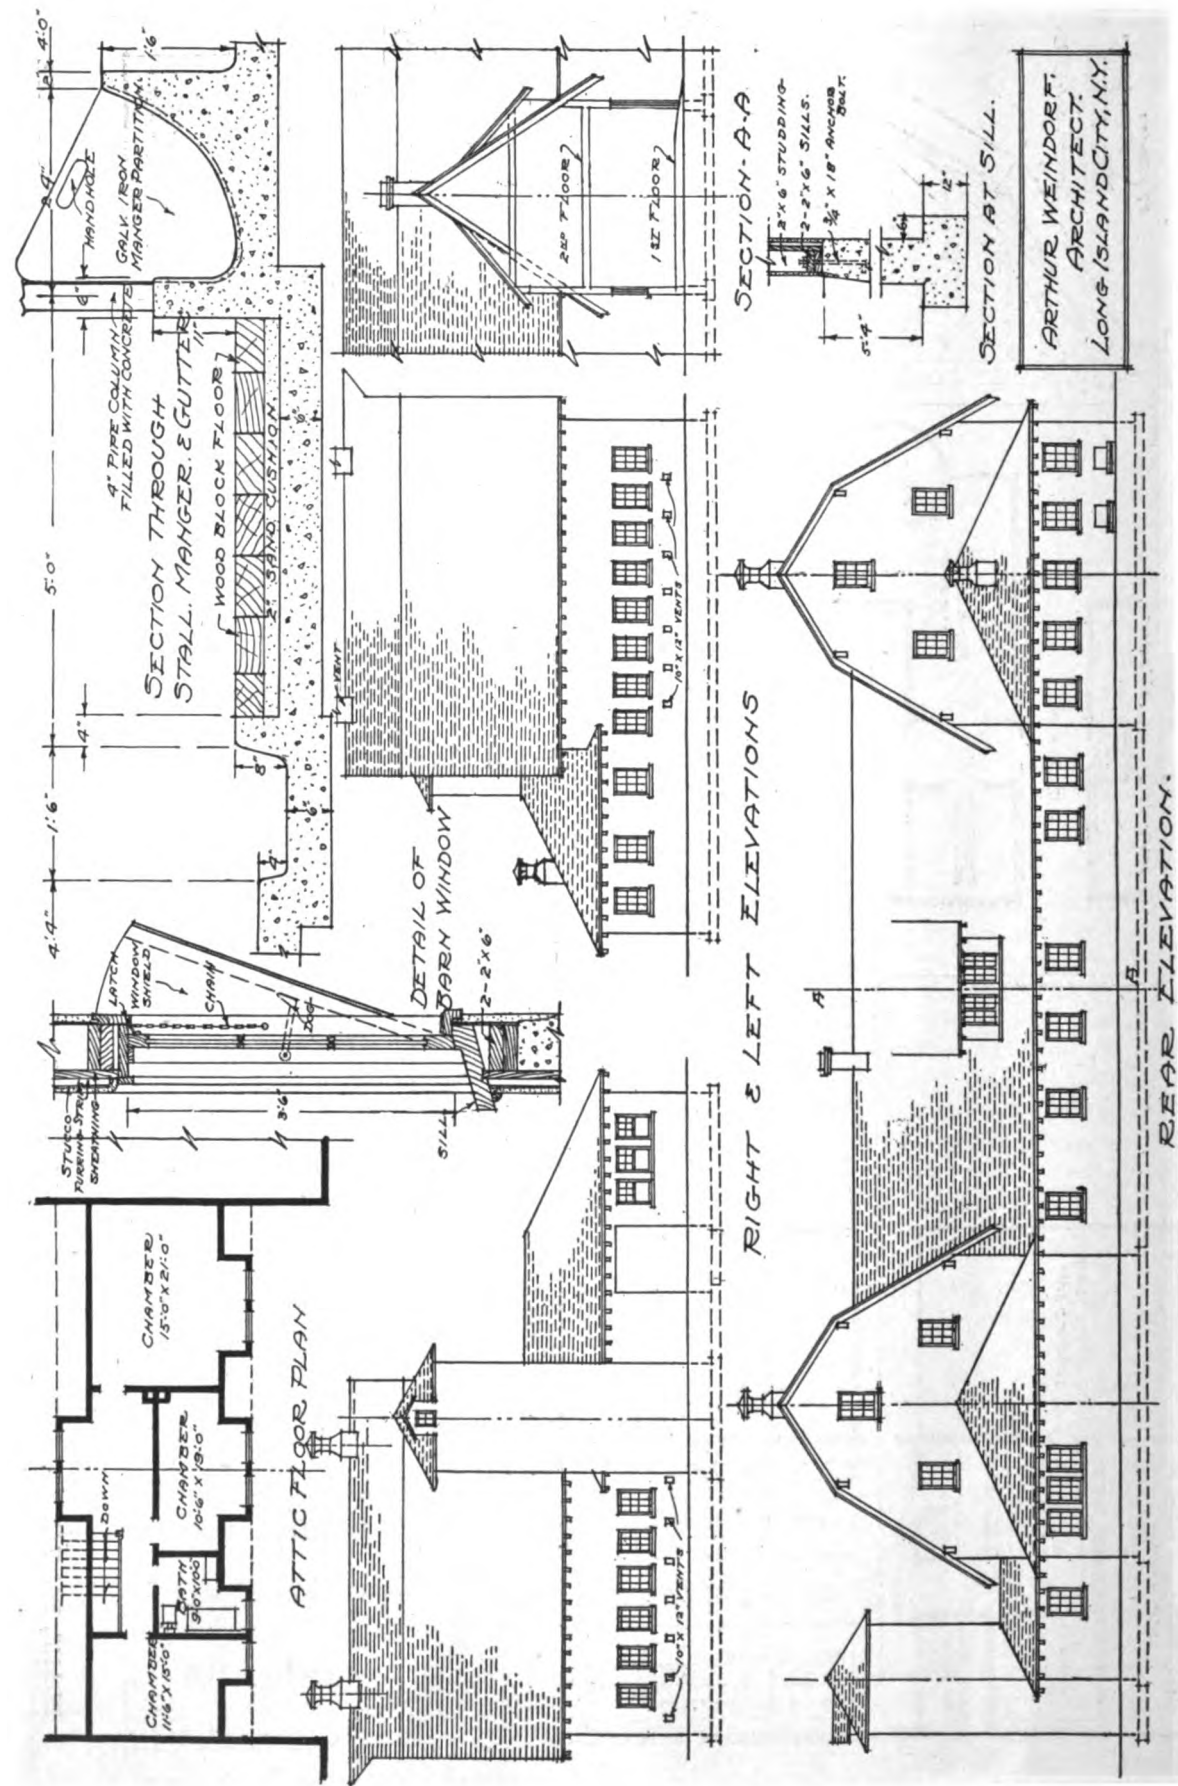

The flues are carried up inside of the exterior walls and between the ceiling joists to the center portion of the barn, where registers are located in the ceiling and in front of the live stock. The purpose of starting the fresh-air flues on the outside within a few feet of the ground is to trap the warm air in the stable. Warm air is lighter than cold, and therefore cannot get out through the intake flues. The air at the ceiling, being the warmest, the fresh air is gradually warmed as it ascends and the fresh air always reaches the noses of the live stock at the right temperature before passing over the gutter, and is drawn off by the outtake flues. The intake and outtake flues should

FRONT VIEW OF A COMBINATION BARN FOR A MODEL FARM WITH SILO IN THE BACKGROUND.

PLANS, ELEVATION AND CONSTRUCTIVE DETAILS OF MODERN FARM BUILDINGS SHOWN ON COLORED SUPPLEMENTAL PLATE

PLAN, ELEVATIONS AND MISCELLANEOUS CONSTRUCTIVE DETAILS OF FARM BUILDINGS SHOWN ON SUPPLEMENTAL PLATE

be so spaced and located that the fresh air will be thoroughly diffused, thereby preventing any drafts which would be detrimental to the live stock.

THE FOUL AIR FLUES

The foul air flues should start on the inside near the floors and terminate in flues above the roof.

An opening in the outtake flue should also be provided at the ceiling so as to remove excessive moisture.

All windows are to be built of pine and are to be so arranged with a wind shield that no draft will be created. The arrangement shown in the detail presented on another page tends to throw the air upward where it will mingle with the warmer air before coming in contact with the live stock. There are many types of barn windows and ventilating systems on the market, meeting almost any need.

An examination of the floor plan shows the relative position of the ice house to the dairy or milk house, and should be constructed in connection with a farm building, being of great convenience.

The ice house is to be thoroughly packed for summer, the ice and sawdust being put in through the side door which is so made that when shut it is practically air tight. When ice is wanted it is taken out through the door opening into what may be termed the vestibule.

THE ICE HOUSE

The ice house is built of hollow tile, starting from the top of a concrete foundation. The air chambers in the hollow tile serve as insulation and tend to prevent the heated air of the summer months from penetrating into the ice chamber. The interior walls are covered with a waterproof insulating board. The proper storing of ice depends on drainage and insulation and having a sufficient quantity of ice in one mass to preserve a temperature below freezing.

The poultry house should be built snug and comfortable, with plenty of light and ventilation, so that the hens will lay in mid-winter. The outside walls are to be built of 2 x 4-in. studs, resting on a concrete foundation. Composite metal lath is to be nailed on to the exterior and interior of the studs and the lath covered with stucco on the exterior and interior, where it is to be troweled smooth. This scheme will prevent vermin from finding any hidden places. The above arrangement will also allow for flushing out the poultry house with hose. All fittings are to be of the removable type, so that everything can be taken out into the sunlight for cleaning.

The garage walls are to be of concrete with a metal ceiling.

The exterior and interior of the barn requires very little painting. All that is to be done shall consist of three coats of pure white lead and linseed oil, and it shall be applied in clear weather.

The entire building is to be supplied with running water and the bath room is to contain an iron enameled tub, wash basin and water closet. The barn is to be properly drained to sewer or to septic tank. The lighting is to be by means of electricity.

The cost of a building of this nature will vary

in different parts of the country, depending on the cost of material and labor. For this reason it can be constructed in some parts of the country for less than here estimated. A saving can also be made by using a cheaper exterior and interior construction, such as substituting wood shingles for the asbestos; novelty siding for the stucco exterior, and finishing off the interior with boards instead of stucco.

According to the estimate of the architect, the barn contains 167,940 cu. ft., and the unit cost is figured at 7 cents per cubic foot. He gives the cubical content of the two barns as 92,160 cu. ft.; of the building between the barns as 34,776 cu. ft.; of the poultry house as 13,608 cu. ft.; of the ice house and milk room 9720 cu. ft.; of the bull pen and feed room of 12,636 cu. ft., and of the 12-ft. silo, 35 ft. high, 5040 cu. ft.

Figuring the cost on the square foot basis, he computes the two barns and the building between at 4329 sq. ft., on which he estimates a price of \$2 per square foot for the large buildings and \$1.50 per square foot for the rear additions. He computes the poultry house, ice and dairy houses, bull pen, feed room and silo, at 2142 sq. ft., with a unit price at \$1.50 per square foot.

The total cost, figured on the cubic foot basis, the architect places at \$11,755.80, and on the square foot basis at \$11,871.

The barn here shown was designed by Architect Arthur Weindorf with offices in Long Island City, New York, or care of THE BUILDING AGE, 50 Union Square, New York City.

LOS ANGELES BUILDING PRACTICE

The Master Builders of Los Angeles, Cal., who form a unit in The Builders' Exchange of that city, have under consideration a draft of a general Code of Practice which was referred to them by the directors of the Exchange. The proposed code is intended to standardize practice in regard to the letting of sub-contracts, etc., and is gotten up on somewhat similar lines to the code recently adopted by the Chicago builders.

The general building code drafted for Los Angeles last spring, which has been pigeonholed in the City Council since May, is coming up for action, and a public hearing was called Oct. 3. The provisions of the code that have already been provisionally adopted are said to have saved an appreciable amount of money for builders.

CINCINNATI'S BUILDING MATERIAL EXCHANGE

The Board of Directors of the Chamber of Commerce of Cincinnati, Ohio, has approved a plan for establishing as a subsidiary of that body a Building Material Exchange. The purpose is declared to be to promote the welfare of the city of Cincinnati and of the members of the organization.

NOVEMBER, 1916

Farm Buildings

The present-day tendencies toward greater hygienic and sanitary conditions on the modern farm and especially where dairy products are commercialized renders of more than passing interest the illustrations and descriptive matter which constitute the basis of our current issue. The builder who is called upon to erect the various structures found upon the up-to-date farm must necessarily consider the different phases involved in the work and it is with a view to affording him possible suggestions as to design and arrangement that the greater portion of this issue has been devoted to farm buildings. While frame construction is largely employed there is an increasing tendency toward the use of concrete, hollow tile and even sheet metal in the erection of the modern farm structures.

The results accomplished are in striking contrast to the ramshackle buildings which dotted the landscape in the rural districts in years gone by and which even now can be found in many localities. The tendency, however, is unmistakably toward better things and a better realization of the requirements of healthful conditions where farm buildings are used for dairy purposes. The growing favor of concrete has caused it to be used in connection with the construction of all kinds of buildings, its popularity being due in large measure to its permanence and to its low cost of maintenance in the way of re-

pairs. In the building of the farm house, the various barns, the silo, the ice house, the piggery and the poultry house, concrete in some form is being employed with gratifying results the country over. In the case of many of the buildings, the walls are either of blocks or of reinforced concrete according to preference and circumstances, while in others, double concrete walls are utilized owing to the fact that these give an air space between which tends to render the structure cooler in summer and warmer in winter than would otherwise be the case. While the initial expenditure may be a trifle more than in that of frame construction, the lower cost of insurance, the minimum outlay required for repairs and the greater life of the work are items which in the long run make for economy and which the builder cannot afford to disregard.

Among the illustrated articles in this issue attention should be called to the excellent examples of buildings found on a model farm near Waukegan, Ill., where each is designed in accordance with its present and future requirements and where the individual needs of each structure were carefully considered. The drawings throughout are to convenient scale and presented in such a way as to render them of practical value to the builder while the pictures show the appearance of the completed structures. In the case of the combination farm and dairy barn near Worcester, Mass., the various details are, from the standpoint of the builder, more than ordinarily complete and therefore of special value to him. Another feature in this issue which is of striking interest and value is the article describing the first round reinforced concrete barn ever erected. The floor plan taken in connection with the numerous "progress" pictures serve to enlighten the reader as to the layout of the interior and to the manner in which the work was carried out. Just how sheet metal may be profitably used in connection with farm building construction is also exemplified in a way to prove of the greatest possible benefit to the practical members of the craft.

We feel sure our readers will be interested in the colored supplemental plates which accompany this issue, illustrating as they do two types of farm buildings and serving as excellent mediums for discussion by builder and client. The long winter evenings are rapidly drawing near when the farmer will take up for consideration the improvements and additions which the harvest has demonstrated to be necessary or desirable and the builder, with the current issue of the BUILDING AGE as a basis, can discuss design and arrangement of modern farm buildings in an intelligent and satisfactory manner well calculated to lead to good building contracts for execution when the spring season opens.

CORRESPONDENCE

A Department Where Those Interested Can Discuss
Trade Topics—Every Reader is Invited to Participate

WEDGING A HAUNCHED TENON

From W. H. C., Peoria, Ill.—In looking over a paper published in London and devoted to the interests of the carpenter, I found an inquiry from a correspondent which possibly may interest some of the readers of *THE BUILDING AGE* and I am therefore enclosing a tracing of the sketch which appeared in connection therewith.

The inquirer asked which is the proper method

WEDGING A HAUNCHED TENON

for wedging a haunched tenon—that indicated in Fig. 1 or that shown in Fig. 2. He stated that a technical instructor teaching joinery made use of the method indicated in Fig. 2 declaring that it is the proper way to do the work. Old joiners, however, in the town in which the correspondent resided differed from the instructor and stated that the method shown in Fig. 1 was correct. Perhaps some of the American carpenters and builders will be interested in expressing an opinion in regard to which is the correct and which the incorrect method.

TEMPERING WOOD-WORKING TOOLS

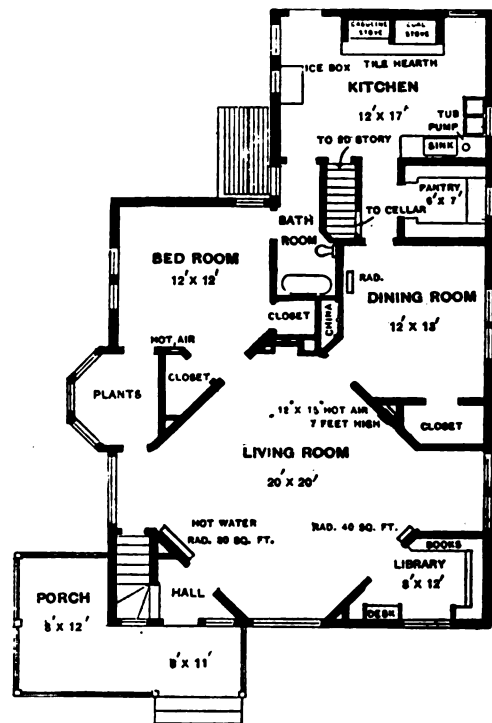

From D. H. C., Oakland, Cal.—A carpenter asked me the other day for an easy method of tempering wood cutting tools, and after I had told him it occurred to me that the same information might be of interest to some of the readers of the correspondence columns, so I am giving it herewith.

Heat the chisels or plane bits or whatever the tools may be to a cherry red, then cool in cold water, after which polish them so as to see the

temper. Next heat a piece of iron sufficiently hot and place the cutting tools on it. Draw the temper to either a dark straw yellow or a slightly brown yellow. If the coal used contains too much sulphur throw on some salt. I would also mention that a little salt used in the water is very good.

NOVEL FLOOR PLAN ARRANGEMENT

From Diamond Room, Red Wing, Minn.—I am sending the tracing of the plan of a first floor showing my idea of arranging the rooms of a house. The benefits to be derived from such an arrangement are large living room, with windows on three sides and the walls of the main living room not exposed to the outside. The latter is a matter of importance in this cold climate. I

NOVEL FLOOR PLAN ARRANGEMENT

should like to have some of the readers furnish an elevation for this plan. I do not care to have more than two rooms in the second story, the kitchen part being one story high. I do not want anything expensive, but on the contrary something plain and substantial of the colonial style.

"SWEATING" OF A CONCRETE COVERED FLOOR

From H. R. T., Peoria, Ill.—I am having some difficulty with a concrete floor, and come to the practical readers of the Correspondence Department of the paper for the purpose of seeking a solution of the trouble. The building is a two-flat structure, and the floors are of cement a half inch thick, laid on ordinary rough wood floors which have been deadened. These floors sweat a great deal, and the moisture at times collects in the low places.

It appears to me that the only thing left to do is to take up this cement floor and put hardwood floors in place of them, but it is possible some of the readers may have heard of similar cases and could suggest a remedy. Personally I cannot conceive of any one putting a flooring of this sort in a dwelling.

Note.—In regard to the above Ernest McCullough furnishes the following reply:

The house in question was examined at a time when the concrete floors were being taken off and oak flooring was being substituted. Thousands of houses have concrete floors and perhaps millions have bathrooms in which the floors are mosaic or tile laid on a thin layer of cement mortar or concrete. No trouble has been reported from them. The usual way in which this work is done is to nail a lath along each side of the floor joists near the top and on these strips rest short pieces cut to fit between the joists. The surface is then swabbed with hot tar or asphalt and on this is laid the cement coating. Floors thus built are always satisfactory.

The Peoria house had under the floors, joists as usual. On the joists was laid a rough flooring on which was placed 2 in. of excelsior in bags. On top of the excelsior was laid another rough board floor over which was placed a coating of cement mortar about $\frac{1}{2}$ in. thick. It is not to be wondered at that the floors exhibited considerable dampness. Compressed excelsior as a collector of moisture is excelled only by a sponge. From experience I had once with excelsior supplied to me in thin bags to be used as an insulator in a small ice house I can certify that it seemed to absorb every ounce of loose moisture there was in the surrounding atmosphere before we got it into the wall.

In the Peoria house the excelsior was placed between two floorings of rough boards and no doubt was in place for some time before the cement plaster was applied to the top flooring. There may have been damp weather which supplied the excelsior and joints and rough boarding with plenty of moisture. We do not know but that it may have rained once, or several times, before the plaster coat was applied to form the cement floor. Then the concrete was applied and the wood and excelsior absorbed a fresh supply of moisture.

The moisture was stored up in the floor construction, the excelsior holding a very large amount. This moisture would have a tendency to vaporize when the house became warm through use and being

closed up and heated. The vapor as it warmed would rise and coming in contact with the floor cooled by the cement coating on top would condense. The mortar being very dense possessed a high degree of capillarity and thus the moisture was drawn through to the surface where, added to the moisture condensed on top of the floor, from the air of the room, there was produced a condition of dampness very noticeable to all who entered the room.

The owner reported that on damp days he could wipe the floors with a cloth and wring the water from the cloth and that rugs on the floors were always damp. The only cause to be assigned for this is improper construction. We cannot possibly ignore the thousands of successful cement and concrete floors throughout the world.

OIL-MIXED CONCRETE

From O. M. R., West Haven, Conn.—I would like to ask "Contractor," whose letter appeared in the correspondence columns some time ago, what has been his experience in connection with the use of oil in cement and what kind of oil to use. How much of it should be used to a bag of cement? He had something to say in regard to the subject in the issue of THE BUILDING AGE for August, 1914, and I would like to learn briefly the results of the experiments which he was about to make at that time.

Note.—In connection with the above, our correspondent is likely to find much valuable information in the Bulletin issued last year by the Department of Agriculture and entitled "Oil-Mixed Portland Cement Concrete." The Bulletin, which is known as No. 230, points out that the admixture of certain mineral oils in small proportions not to exceed 10 per cent of the cement used does not lessen the tensile strength of the mortar; that the decrease in the compressive strength of mortar and concrete is not serious; that concrete mixed with oil takes much longer to set hard—perhaps twice as long—but that the increase in strength is nearly as rapid in the oil-mixed material as in the plain concrete. The use of oil does not make the concrete impervious to heavy water pressure but practically non-absorbent under low heads.

The value of oil-mixed concrete is particularly great in the construction of basement floors and walls, watering troughs, cisterns, barns, silos, and in all parts of concrete structures that are to be made damp-proof.

The oil should in no case exceed 10 per cent of the weight of cement and for the most part 5 per cent is all that is necessary. In other words, about $2\frac{1}{2}$ quarts of oil should be added for each bag of cement used in the mixture. The oil should be fluid petroleum product and should contain no admixture of fatty or vegetable oils. It should show a flash point of not less than 150 degrees Centigrade by the closed-cup method.

The sand and cement should be first mixed with the proper amount of water into a stiff mortar to

which is added the correct amount of oil, and the whole mass again thoroughly mixed until all traces of oil have disappeared. Particular care should be taken to insure that the oil is thoroughly incorporated in the mixture and the time of mixing should be practically double that when the oil is not used. For this reason it is pointed out a continuous mixer should not be used in oil-cement-concrete work as it is difficult with this type of machine to increase the time of mixing sufficiently.

CONSTRUCTING AN ORDINARY SHED

From D. P. B., Redford, New York.—Referring to the problem of "W. M. L." on page 56 of the September issue, I would say that he can solve it in three ways. First with the steel square, taking the figures one and twenty-four and cutting each piece by those figures. Second, he can square out from each run holding the heel of the square at the angle as in Fig. 1. An angle will be produced by the two lines. Bisecting this the cuts are obtained. Third, he may obtain the cuts by using two graduated bevels. If these are not at hand he may use two bevels with tongues of equal length bring-

of this and a plate on top of them which will support the roof.

To my mind, 18 ft. is a pretty long span for a single rafter so I would suggest spiking two studs together or use a solid post in the center as shown in the side view and spike two 2 x 8's together and run them across the shed as shown, resting the ends on these posts. Now he can use a long rafter or he can splice them on this beam. I would make a butt joint with the outside rafters nailing a board on the inside at the joint and lap the others and spike them together. I would bevel the rest of the side studs on the top end so as to fit under the side rafters.

Let the sheathing project over the side and nail a board on the front and back end of the rafters, also run a board down the side, nailing it to the

Fig. 1—Bisecting the Angle

Fig. 2—Obtaining the Cut for Bevels as Suggested by "D. P. B."

Fig. 3—Front and Side Elevations of Shed as Described by "W. S. W."

CONSTRUCTING AN ORDINARY SHED—SKETCHES OF DIFFERENT CORRESPONDENTS

ing the points exactly together as indicated in Fig. 2. If his bevels are of unequal length he should mark the length of the short one on the long one.

From W. S. W., Hillsboro, Ohio.—In answer to the query of "W. M. L.," Orange, N. J., in the September issue of the paper, I am sending sketches with brief description which I hope will help him in constructing the shed for which he asks information. Fig. 3 shows a front and end elevation. I do not mean that it should be built exactly as I have shown it but I have aimed to bring out the main points so as to give him something which will serve as a guide in doing the work.

If the correspondent has a solid foundation he can use a 2 x 4 in. or 2 x 6 in. sill and 4 x 4 in. corner post. I would suggest using a double stud each side of the door running the outside ones through to the plate as shown in the elevation. I would use two 2 x 6's or 2 x 8's spiked together as a lintel allowing the ends to rest on the two inside studs. Then he can put a few short studs on top

ends of the sheathing and to these boards. This stiffens up the ends of the sheathing and makes a finish for the edge of the roof.

The front of the shed is 1½ ft. higher than the back so take 1½ in. on the tongue and 18 in. on the blade of the square, and the tongue will give the plumb cut while the blade will give the seat cut. The tongue will also give the bevel for the top end of the studding on the side of the building to fit under the rafters.

The doors may be hinged or sliding according to preference. If sliding doors are used the track may project past the building and have a brace under it.

VARNISH FOR TOOLS

From M. R. N., Washington, D. C.—Please give me a receipt for varnish to keep bright tools and similar goods from tarnishing.

Answer.—A receipt given as a varnish for tools is as follows: Melt together 40 ounces of tallow

and 2 ounces of rosin and strain while hot; apply with a brush to tools and it will prevent them from rusting. Another receipt described as a varnish for polished metal is to pound bleached shellac in a mortar and then put it in a bottle of alcohol, agitating the alcohol frequently until it has dissolved as much shellac as it will; then pour off the clear liquid. The metal surface is first warmed and the varnish applied to it with a brush, giving a transparent coating that will protect the polished metal.

GETTING OUT CURVED VALLEYS FOR GREENHOUSE CONSTRUCTION

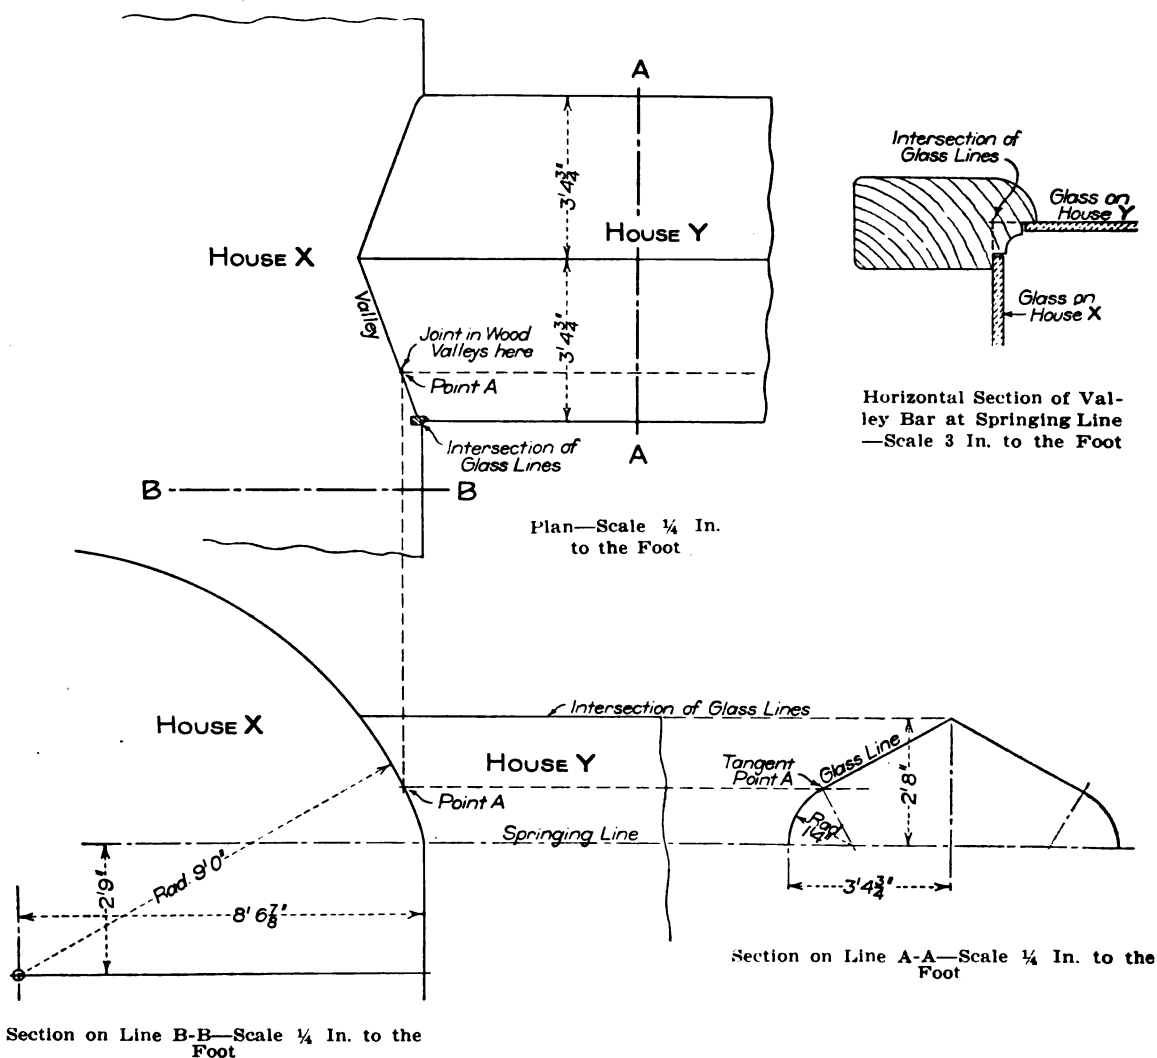

From C. G. P., Newark, N. J.—I am sending a tracing showing the two curved valleys for greenhouse construction, and would be greatly obliged

of the valley bar is to be $1\frac{7}{8}$ in. the entire length of the valley, but the height may vary slightly.

I take pleasure in stating that I am a subscriber to the BUILDING AGE, and have gained much practical knowledge from its various issues.

DIMENSIONS OF SMOKE CHAMBER IN A FIREPLACE

From E. B. A., Mount Vernon, N. Y.—I am going to build a fireplace in my house, but do not know how big I should make the smoke chamber. Is there any particular height to it above the smoke shelf? Is there any stated relation between the cubical content of the smoke chamber and the cubical content of the fireplace or between the area of the smoke chamber and the area of the

DETAILS OF CURVED VALLEYS FOR GREENHOUSE CONSTRUCTION

if some of the practical readers will give me a good clear method for getting out shop drawings for this and similar two-curved valleys.

In this case the valley bar may be gotten out in two pieces, a splice being made at the tangent point of the 16-in. rod marked "A" on the drawing. The idea is to get the bars out of the smallest possible pieces of timber. The thickness

fireplace opening the same as there is between the fireplace opening and the flue area? I would also like to know if the middle of the throat is directly over the middle of the fire chamber.

Note.—This letter offers excellent opportunity for a most interesting discussion of a subject which is constantly perplexing the builder owing to poor draft of chimneys, smoky fireplaces, etc.

EQUIPMENT FOR THE MODERN DAIRY BARN

SOME PERTINENT COMMENTS FROM A SANITARY POINT OF VIEW BY AN EXPERT

By W. L. WEINTZ*

IT is only in recent years that the general public has given much thought or consideration to the vital question of sanitation in food supplies. Just why the American people have been so indifferent in the past does not concern us at this time, since the demand for clean and palatable food is now heard and respected in all communities. Much has been said and written on the subject of canned meats, etc., and none will dispute the satisfactory and beneficial results accomplished by such publicity.

According to recognized experts, however, there is no one food product largely assimilated by the human family which is so susceptible to contamination as cow's milk. The mere presence of slight foreign matter is sufficient to taint and contaminate the purest milk, and this fact makes it imperative that proper care and precaution be exercised by dairymen who are conscientious and honorable. In many localities it is no longer a question of an individual's conception of sanitation, since measures have been adopted by state legislatures regulating the production and sale of dairy products. There is no doubt in the mind of the writer that this movement will soon penetrate even the most obscure rural districts, for

people are daily learning more concerning the need of sanitary measures, and their demands must be considered by the producer and dispenser.

The logical place to begin operations in making an investigation of dairy products naturally is among the producers themselves, viz., the dairy cows. It need scarcely be pointed out that milk for human consumption must come from a healthy animal. The interest in breeding circles would indicate that this phase of the question is receiving proper consideration, and with the aid of modern knowledge on the treatment of disease among domestic animals there is no excuse for polluted milk

being sold. It is therefore highly important that dairy herds be inspected at frequent intervals and the stock all kept in best possible condition.

In how many cases, though, is contaminated milk not primarily due to the animal, but to the conditions for which the owner himself is directly responsible. No matter what breeding or pedigree a dairy cow may have, if she is confined in a dark, poorly ventilated and filthy barn, her chances for producing certified milk are nil. With the invention and manufacturing of sanitary barn fixtures the public can no longer countenance disgusting barn conditions, and most dairymen have shown a marked interest in these modern appliances.

When barn equipment was first placed on the market it was caustically referred to as being adapted only for the rich man's barn, and therefore

could never be of real economic value to the thousands of dairymen who depend on their herds for a livelihood. It is true that wealthy men who took up dairying as a recreation or hobby were first to realize the value of steel equipment for the dairy barn, both from a sanitary and practical viewpoint. Soon, however, the larger producers were con-

FIG. 1—VIEW DOWN MAIN AISLE IN A BARN FITTED WITH MODERN EQUIPMENT

strained to investigate the manufacturer's claims regarding the advantages derived from an installation of this equipment, and gradually they came to see that their former views were unfounded and incorrect. At the present writing more and more dairymen are remodeling their barns and installing modern equipment, with the natural beneficial results to the community at large.

The value of steel barn fixtures is not confined to the sanitary conditions made possible by its use. It has been satisfactorily demonstrated that less labor is required to care for a given number of cows, that a marked saving in feed is noted, that cows are more comfortable and give a greater quantity of

*Illustrations courtesy of the J. E. Porter Co.

milk in those barns having modern equipment. So it will be seen that the consumer is not alone in deriving good from this up-to-date practice. It is merely a question of time until all dairymen will realize and acknowledge that the possibilities of their herds are exceedingly limited unless modern methods are pursued in their management.

Few people consider a dairy barn in the light of a manufacturing plant; yet that is precisely what it is, and incidentally a food product for universal consumption is manufactured there. It is only reasonable that we should expect to find the most approved machinery with efficient, skilled workmen performing their duties under comfortable conditions. In a modern dairy barn that is exactly what you will find, and furthermore, the owner will doubtless be a man of affairs and a recognized authority on his business. Dairying is no longer a haphazard side issue on the farm, and milk is now considered in many localities on a quality basis. Usually the degree of butter fat determines the market value, and the dairyman is at once concerned when for any reason his product fails to meet the standards established.

The accompanying illustrations will convey some idea of the equipment in a modern dairy barn. Note that provision is made for the cows to line

is made of steel and the entire barn can be thoroughly scrubbed without damaging the fixtures. Swinging stanchions which are flexible at both top and bottom connections enable the cows to turn their heads in comfort, and relieve in a marked degree the forward

FIG. 3—ANOTHER INTERIOR SHOWING THE FEEDWAY WITH COWS IN THEIR STALLS

thrust of the body when an animal gets up or lies down. Steel mangers or manger partitions make it possible to feed each cow according to her particular requirements—something very important in modern dairying. An abundance of light and fresh air penetrates all parts of the building, and the animals can thus be kept in excellent physical condition.

The task of handling feed and litter is one which without modern equipment would entail excessive labor in a large barn. Easily operated and efficient carriers are therefore provided for this purpose and with their aid the work which formerly was irksome and disgusting becomes such that the owner himself has no hesitation in performing it. Litter carriers make it possible to keep the manure away from the barn and modern practice suggests one of two methods for handling litter. Either it is dumped from the carrier directly into the spreader and placed on the field, or the carrier conveys it to the manure pit, where it is treated somewhat and the fertilizer value augmented. Some legislative measures prohibit

FIG. 2—INTERIOR OF DAIRY BARN IN SOUTH CAROLINA, SHOWING STANCHIONS, STALL SEPARATIONS, ETC.

up along the gutter, thus having all droppings in one place rather than on the stall platform. The gutter is somewhat deeper than the rest of the floor, and the animals may lie down in comfort without covering themselves with filth. All equipment is

litter is carried a certain distance away from the barn. In view of the movement under way for more stringent regulation of milk supply, it naturally behooves every dairyman to investigate his shortcomings and take steps to remedy them.

A ROUND REINFORCED CONCRETE BARN

"PROGRESS" PICTURES SHOWING CONSTRUCTION OF FIRST BARN OF THIS KIND ERECTED

WE take pleasure in presenting herewith illustrations and descriptive data relating to what is said to be the first round reinforced concrete barn ever constructed in this country. The building contractor executing the work states that this claim is based upon information from various authentic sources, including among others the Agricultural Experiment Station of the University of Illinois, and we are indebted to him for the particulars and "progress" pictures here presented.

Reinforced concrete was selected for its permanence and the round shape for the convenience of stable arrangement, large unobstructed loft for hay storage and the relatively small amount of material required to do the work. The concrete used was a 1:2:2½ mixture, the proportions named being due to the fact that local gravel was utilized. The reinforcing material was ¾ in. square twisted steel spaced 12 in. on centers both horizontally and vertically and held in place partly by "Universal chairs" and partly with "Bates" ties.

Wood forms were used on the job, there being two complete sets inside and outside, each 3 ft. high and in sections about 8 ft. long. The builder states that considerable care was used in making the forms, as he depended upon them for the plumb lines of the wall. The rails on the forms were horizontal; three to a section, about 1 x 5 in. in size, and fastened together by splice pieces and half-inch bolts for the inside forms. This arrangement proved sufficient for the purpose. The outside forms had to be strengthened by the use of half-inch wire cable hoops tightened up with draw-lugs, and for this work tank hoop fittings were utilized.

In making the forms it was found that the rails would spring out of shape when sawed, and difficulty was experienced in sawing them accurately. A band saw was first tried, but it was found that an ordinary circular saw worked better as the curvature was not great. In order to bring them to the

exact shape the contractor used a template tacked to them and jointed them on an upright moulder, allowing the template to run on a collar on the spindle.

Clay of about the consistency of ordinary putty was used for filling cracks, etc., in the form work. A very cheap fuel oil worked well on the forms—not so much to keep the concrete from sticking as to check the shrinking and swelling of the lumber.

The builder states that 100 cu. yd. of concrete in a round building like the one here described provides equal stable room and a much larger loft space than 200 cu. yd. in a rectangular building.

For the purpose of making the roof a self-supporting dome and at the same time reduce the concrete in the walls to the lowest practical point use was made of two tension members sufficiently rigid to maintain their circular shape.

The reinforced concrete cornice and plate at the top of the concrete wall was made 10 in. deep and 18 in. broad in which, in addition to all vertical wall reinforcing being bent out through it, there were placed five ¾-in. square twisted horizontal reinforcing bars. A detail of the main cornice with the position of the reinforcing

GENERAL VIEW OF THE COMPLETED BARN

ing bars clearly indicated is presented herewith.

This member maintains the circular shape of the walls, which above the loft floor are only 6 in. thick, and receives the thrust to the first set of rafters, which are 2 x 6 in. by 28 ft. in length, placed about 25 in. on centers and running at an angle of 30 deg. from the vertical to the hip in the roof, where they are about 15 in. on centers.

At the hip and securely spiked to the lower rafters, which are cut off square, is the second tension member in the form of a 7 x 9-in. wooden plate made up of six layers of selected oak plank fastened together with about 150 lb. of nails and spikes. The layers of this plate being sprung down to fit the square cut on the ends of the lower rafters do not form a plane but are 30 deg. lower on the inside than on the out, thus making this plate saucer-

shape and providing a direct bearing for the thrust of the upper rafters which are 2 x 6 in. in cross section 27 ft. long and run to a point at the center of the building at an angle of 30 deg. with the horizontal. As these two plates and sets of rafters constitute the entire roof framing, the practical builder will readily see that a very light construction was produced.

In the lower section of the roof, it was found that merely lathing it made it quite rigid, but to assure strength independent of the lath, solid 2 x 6-in. bridging was cut in between the rafters all the way around the building about 9 ft. apart, thus preventing sagging of the rafters.

In the section of roof above the hip, which is about 47 ft. diameter, 18 rafters 2 x 6 in. and 27 ft. in length were run to the center of the building. These, when erected, showed considerable sag, but a set of headers was cut in between them about 6 ft. from the center to which to fasten an intermediate set of rafters. By cutting these headers of good length and forcing them in it was possible to force the sag out of the main rafters. The same process was pursued with another set of headers lower down the roof which received a still shorter set of rafters and also with a circle of solid 2 x 6-in. bridging still lower down, with the result that a

building, no vibration could be detected in the roof. The dome of the building is covered with 6 x 20-

Detail of Concrete Cornice—Scale $\frac{1}{4}$ In. to the Foot

in. white cedar shingles laid 6 in. to the weather.

Among the equipment used in doing the work was a small concrete mixer, a 5-hp. Fairbanks "Bull-

Floor Plan of Round Reinforced Concrete Barn—Scale $\frac{1}{16}$ In. to the Foot

stiff construction was produced with about a 2½ in. crown in the rafters.

The builder says that during a gale of wind that capsized two sail boats on Delaware Bay near the

dog" gasoline engine and a home-made saw rig, the interesting feature of which was the mandrel. This had a 4-in. space between collars, allowing the use of emery wheels, shaper bits or jointer head.

**"PROGRESS" PICTURES SHOWING DIFFERENT STAGES OF THE CONSTRUCTION WORK
ON THE ROUND REINFORCED CONCRETE BARN**

It was turned out on the other end for a No. 3 Morse twist drill sleeve of standard taper. These drills, with a little special grinding, were found quite satisfactory for boring wood when running 1600 revolutions per minute, which was the speed of the saw mandrel. The derrick was also home-made and fitted with ball bearing turntable from a local machine shop.

Referring to the "progress" pictures, No. 1 shows the inside forms 1 ft. below grade and 5 ft. above, with two sections in place. The outside forms showing a foot of concrete wall, are 4 ft. high above grade. The door frames are in place.

No. 2 represents the process of pouring concrete,

of the equipment, there being no shoveling required except into barrows which dump into the concrete mixer, the latter into the bucket and this in turn into the forms.

No. 7 represents the first story completed, also the reinforcing scaffolding and section of forms ready to be raised.

No. 8 shows the forms and reinforcing in place with everything ready to "pour" the concrete.

No. 9 is an interior view with the loft floor in place around the wall.

No. 10 shows the form box for the concrete cornice with reinforcing rods in position.

No. 11 represents the scaffolding for the roof

"PROGRESS" PICTURES OF THE FIRST ROUND REINFORCED CONCRETE BARN
ERECTED IN THIS COUNTRY

the bucket having a capacity of 7 cu. ft. Some of the reinforcing material is in place and the wire cable hooping of the forms may also be seen.

No. 3 shows the inside forms 8 ft. high and the stable door and window frames in place. The derrick has a 52-ft. mast and a 50-ft. boom on ball bearings. The gravel pile is seen at the right.

No. 4 shows the complete equipment of outside forms in place. The concrete mixer and circular saw rig are in the foreground. The saw rig is driven by an engine inside of the forms which also does the hoisting.

No. 5 shows girders and joists being placed extending through the forms into the wall. The hoisting engine is also visible which runs the concrete mixer and the saw.

No. 6 clearly indicates the convenient location

placed on the loft floor and 32 ft. high. The first set of rafters are shown in place.

No. 12 shows the lathing for the roof.

No. 13 shows the roof partially completed, there being required to cover the entire dome 30,200 shingles.

The concrete barn here shown was erected for H. McDaniel on his farm, "Cherbourg," near Dover, Del. It has a capacity for 18 horses, 30 milch cows, 20 head of young stock, 200 tons of hay and 200 bu. of grain.

It is 72 ft. in diameter and 61 ft. in height. The concrete walls are 20 ft. high, the stable walls 8 in. thick and the loft 6 in.

The barn was designed and the erection supervised by W. M. Newton, a contractor making a specialty of concrete work, Dover, Del.

MAKING HAND-RIVED CYPRESS SHINGLES

SOME INTERESTING PARTICULARS REGARDING THIS IMPORTANT SOUTHERN INDUSTRY

THE attention which builders are giving to old-fashioned rived or split shingles renders the story of their making one of more than passing interest. Many of the shingles produced are the work of negroes working independently, but perhaps most of the best shingles are the work of men laboring under the supervision of a large concern which sees that a standard is established and to which it is adhered.

The process described in the following lines is that followed by negroes working in the Black River Swamp, which is near the southern boundary line of South Carolina, the finished product emerging as that of the Hammer Lumber Co., Philadelphia, Pa. The

specimen of swamp cypress, and this is then subjected to various tests. The bark is examined, and if it is straight up and down the tree will split right. If it is "twisted from east to west" it should split, but if the twist is from west to east it will not. Next, a chip is taken from the hardest part of the tree which, in a leaning tree, is on the under side and in a straight tree is on the sunset or west side. Finally a piece is chewed and if it chews all right the worker is satisfied that the tree will split good and draw smooth under the draw-knife; hence is "meat" for shingles.

In the tree felling operation and in the subsequent cartage of shingles, the reader should

Fig. 1—Buck-sawing a Cypress Tree into Lengths for Making Shingle Bolts

Fig. 2—Splitting the Bolts in Slabs

Fig. 3—Using the Draw Knife in Shaving the Shingles to Size

PICTURES SHOWING SOME OF THE VARIOUS OPERATIONS

various steps are often somewhat amusing, being evolved from the fertile imagination of the negro workers.

First, the proper thing to do is to pick out a good

keep in mind that the process is conducted in a swamp and that various precautions are taken because of this fact. First, several small trees are felled and placed so as to form a "cradle" or bed

upon which the cypress tree is to fall. This cradle prevents the tree from being spoiled in its fall and also keeps it from sinking in the marshy swamp soil. A scaffold is then built around the base of the tree for the workers to stand on while felling it.

After the tree is felled it is buck-sawed into lengths which will allow of full-length 24-in. shingles, the buck-sawing operation being shown in Fig. 1. These lengths are then cut into bolts $7\frac{3}{8}$ in. wide. The bolts are then rived or split into slabs 1 in. thick by a wedge-shaped knife set at right angles to its handle and worked with a wooden mallet, as shown in Fig. 2.

Finally the slabs are placed in the draw-bench or "break," and worked with a draw-knife, being shaved down to a $\frac{5}{8}$ -in. butt, and the usual shingle taper. As shown in Fig. 3, the draw-bench holds the slab tightly by means of a treadle. The slab extends over the end of the draw-bench toward the worker, much in the manner of a springboard. This springboard effect aids the worker to secure the proper taper.

The shingle now measures 7 x 24 in., and has a $\frac{5}{8}$ -in. butt. It is stacked up with others to make piles of 500, or a square "pen," and is then inspected. The entire process is carried on within a few feet of where the tree stood, each worker producing about 1000 shingles per week. Lastly, bundles of twenty-five are made and fastened with wire and the finished product is carried on the shoulders of negroes to high ground, the road traveled being rough and perilous, as in many places the path is formed of single tree trunks.

Once on high ground, the shingles are allowed to dry for from sixty to ninety days, and are then carried on to the railroad siding for further inspection and stenciling. They are then shipped as the "Hammer Brand." As indicated by the foregoing description, the process is entirely by hand, and interesting because of its primitiveness in these days of machinery and high-speed output.

A BOOK ON LIGHTNING RODS

Contractors and builders who are interested in the use and value of lightning rods will be glad to learn that the subject is covered in a very thorough manner by O. S. Peters, assistant physicist of the Bureau of Standards. The work is valuable from a statistical standpoint, and traces the early history of the lightning rod to the present status of the practice of protection against lightning.

There are twelve chapters, covering 127 pages, in which there are numerous tables and photographs. Attention has been given to materials and construction of lightning rods, earth connections, arrangement of rods and other important matters, while the question of cost is also considered. It is shown that the liability of barns to fire from lightning, as compared with their liability to fires from other causes, far exceeds that of houses. It is said that in the cases of 200 barns struck by lightning 87.5 per cent were fired, while of 325 houses 23 per cent were fired. It thus appears that,

when struck, barns are practically four times as liable to take fire as houses.

The book is identified as No. 56, Protection of Life and Property Against Lightning, Technologic Papers of the Bureau of Standards, and may be procured from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 35c. a copy.

MODIFICATION OF NEW ZONING LAW

The Board of Standards and Appeals of New York City adopted on Oct. 4 a resolution extending until July, 1917, the time in which builders, who through an oversight neglected to comply with the new zoning laws, will be allowed to erect their structures without being subject to a penalty. The board decided to allow this modification because it believed that many builders had not had time to familiarize themselves with the provisions of the changes provided under the new zoning laws.

PATCHING CONCRETE FLOORS

One of the principal objections often raised against the use of concrete finished floors is the difficulty and cost of successfully repairing places that become worn or damaged. For best results it is usually considered necessary to cut down the worn place at least $1\frac{1}{2}$ in. into the unbroken concrete, under-cut the edges, clean out the dust and loose particles thoroughly, wash with a thin cement grout, fill in with a paste grout and finally float to a level surface a mortar of cement and crushed stone or gravel. The patch must then be kept moist at least a week or ten days, keeping all traffic off in the mean time.

W. P. Anderson, president of The Ferro Concrete Construction Company, states that his company often uses a method of patching concrete floors which is much cheaper and requires far less time than the method commonly used. Mr. Anderson's method requires the use of mastic material made from a mixture of asbestos fiber and rubber gum. This mixture is applied with a trowel after thoroughly cleaning the damaged surface. Very little cutting of the old concrete is necessary, other than to break off loose particles. The gum can be worked to a feather edge so that it will readily join with the undamaged concrete surface and eliminate the under-cutting required with the old style of patch.

A patch of this sort can be opened to foot traffic within a few hours, and to heavy traffic within a day or so. It is thus possible to repair a much-used portion of a mill or factory floor almost overnight. The cost varies with the size of patch, but will range from 16 to 18 cents per square foot.

It is estimated by the Forest Service of the United States Department of Agriculture that there is enough waste from the sawmills of the South alone to produce 20,000 tons of paper a day.

USE OF SHEET METAL ON FARM BUILDINGS

ITS FIRE AND LIGHTNING
FEATURES OF VALUE TO

PROOF QUALITIES ARE
THE PRACTICAL BUILDER

WE have been hearing a great deal about preparedness since the outbreak of the European war, and it is evident that the nation that does not prepare itself against the attacks of its enemies will soon be overwhelmed. The same is true of farm buildings, for they have numerous enemies, and, unless they are prepared to withstand the onslaughts of fire, lightning, and other destructive elements, are more than liable to succumb sooner or later. Many farmers with large and well equipped barns, housing valuable registered and pedigreed stock, overlook the fact that they are not fully protected from loss by fire, even though they have their property insured for its entire valuation.

Statistics show that numerous opportunities await the enterprising contractor to do a larger

criminating builder. Steel roofs and walls are permanent and command lower insurance rates. They have durability and long life, which, combined with the ease of application and minimum cost of maintenance, render them adaptable for use on farm structures. Buildings covered with sheet metal can be made attractive and will present an effectual resistance against the continuously active attack from the elements. It is claimed that a structure completely covered with sheet metal and properly grounded is lightning-proof and more dependable than a building simply equipped with rods. A good sheet metal roof is capable of withstanding the attacks of its most destructive elements—rain and moisture; and it will resist high winds where sheets are carefully selected with a view toward the great strength and rigidity needed.

A MODERN FARM BARN WITH STEEL ROOF AND SIDING

business in metal roofing, siding, cupolas, etc., for use in connection with farm buildings. The field is not confined to new structures, for there are thousands of farm buildings that could be made more serviceable and the property more valuable if the roofs and walls were covered with sheet metal. All-metal structures have been accorded a popular reception in the country, and the work is profitable to the builder and is especially desirable in the dull season.

There are many features in connection with sheet metal work that commend themselves to the dis-

This is especially true of corrugated sheets, which are practically self supporting, and will make a building very substantial even when the framework is light. The use of corrugated sheets permits of light construction, and the sheets properly laid will not check or crack at the seams.

Sheet metal roofing and siding can be applied to any farm building at a comparatively low initial cost, but the character of the building should be considered to determine the kind of material best suited for its purpose. There are several types of roofing and siding, notably, pressed standing seam roofing,

V-crimped roofing, roll and cap roofing, corrugated roofing and siding, weatherboard siding and steel pressed brick siding. Generally speaking, where the roof pitch is less than 3 in. to the foot, roll and cap or pressed standing seam roofing is best, while

SHOWING USE OF SHEET METAL ON A
POULTRY HOUSE

a pitch in excess of this may be covered satisfactorily with corrugated or V-crimped roofing. Beaded ceiling or siding may be easily applied directly over level joints, to rough sheathing or over plaster. In weatherboard siding the contractor is offered a fire-proof substitute for wooden weatherboards, and its attractive appearance makes it quite suitable for any structure where looks is a factor. It can be applied without any trouble where sufficient care is taken to keep the lines horizontal. Weatherboard siding may be nailed directly to the studding placed 16 in. on centers, or to sheathing boards. Steel corner boards are recommended to give a neat and finished appearance at the corners.

A pressed standing seam roofing is a serviceable type and gives an attractive appearance to any building on which it is applied. A ridge roll or ridge capping is not essential in this style of roofing, but can be used as a trimming, if desired.

Roll and cap roofing is used on roofs having only a slight pitch, or a fall of less than 2 in. to the foot. An explanation for this is found in the fact that roll and cap roofing comes in rolls of 50 lineal feet and the cross-seams which occur every 10 ft. are perfectly formed by machinery. When the flanges are bent up, the cross-seams extend to the top of these flanges on either side, insuring an absolutely leak-proof surface. The tools required to lay roll and cap roofing are a punch, cap squeezers and a pair of roofing tongs for turning up the flanges for side seams. Roll and cap roofing is best applied to sheathing which entirely covers the rafters. Self-capping and roll roofing offers the same advantages for nearly flat roofs as roll and cap roofing.

In applying corrugated roofing to wooden framework, it is considered good practice to ascertain first from which direction the heavy winds blow and begin laying the roofing at the opposite end of the roof, laying the first sheet at the lower corner. A very strong roof, absolutely free from leakage, may be obtained by applying 3 in., 2½ in. or 2 in. corrugated sheets 27½ in. wide, lapped 1½ corrugations to each lap. This gives a covering surface of 24 in. to a sheet. While the roofing is being put on it is advisable to paint between the laps, as this

aids in making the roof watertight. A prominent manufacturer says that it is best to apply light gauge corrugated roofing, say 26 gauge, to close sheathing or common stock boards and not directly to the rafters. With heavier gauge material sheathing will be found unnecessary, the corrugated sheets being applied directly to purlins. For this work 1 x 4 in. stuff, about 8 in. apart, will be found serviceable. If the underside of the roof will be subjected to hot air, steam or sulphurous fumes, a felt lining should be used between the sheathing and the roofing.

A lead washer should be used with every nail that is put into sheet steel roofing or siding. The washer makes a watertight joint under the nail head and prevents all leakage and rusting at that point.

For siding on wooden framing, heavy gauge corrugated material is regarded with most favor, as these sheets can be nailed direct to the studding. The elimination of sheathing effects a saving in the lumber bill and the construction work is facilitated. Siding should be started at the bottom, always using a baseboard, which will keep the sheets from contact with the soil and its corroding elements, and a long life, free from rust, is made possible for the bottom row of sheets as well as for other portions of the structure. In any building where there is likely to be pressure from the inside, it is advisable to use enough sheathing boards to prevent this strain from bearing on the metal sheets. Such sheathing will be found necessary in a barn where the hay pressure is unusually great. Close sheathing or felt lining should be employed where sheet metal siding is used on stables, as fumes from manure pits are harmful to all metals. The same precautions should be observed with sheet metal roofs on stables.

V-crimped roofing is very easily applied and does not require the use of cleats or any other fastenings, except nails. This roofing may be laid directly over any old shingle roof, on sheathing boards

A COW STABLE WITH SIDES AND ROOF OF
SHEET METAL

placed about 2 ft. apart, or on rafters set 2 ft. on centers. These sheets are applied with V shaped wood strips, 50 lineal feet being required for each square of roofing. One hundred lineal feet of sticks are required for a square of 3 V-crimped roofing, while 4, 5 and 6 V-crimped require no V sticks, as the sheets have enough rigidity without them. The wooden V sticks give so much rigidity that V-crimped sheets may be applied directly to rafters.

If applied in this way, with the upper ends lapped over the lower, it will be found necessary to provide crosspieces nailed between the rafters to give a nailing support for lapped ends where they come.

Experts consider it much better practice, how-

A CORRUGATED IRON POWER HOUSE AND ITS RELATIVE POSITION TO THE BARN

ever, not to lap the ends of the V-crimped sheets but to lock them together as is done in standing seam roofing. This is true whether the sheets are applied to the rafters or over sheathing boards. The use of sheathing boards is to be preferred for V-crimped sheets, as this construction insures a stronger and more durable roof. It is not recommended that such sheets be used where the roof pitch is less than 2 in. to the foot. If V-crimped sheets are put on over old shingles 3 in. nails which will go through the shingles to the sheathing are best for the purpose.

The "ground" connections may be made by using metallic rods that are fastened securely to the metal covering and extended at the other end well into the earth. The earth is the great reservoir of electrical energy and it is always at zero potential. If a discharge of lightning can be directed into the moist earth by a conductor, its energy is soon dissipated, but the "ground" connection should extend well into the moist earth. A piece of galvanized iron pipe, driven into the ground seven or eight feet, makes a good "ground." Large buildings should have two or more "grounds."

The U. S. weather bureau, in a Bulletin on Lightning and Lightning Protection, recommends a No. 3 galvanized wire as sufficient in size for lightning protection. If metallic downspouts are used as con-

ductors, the connections should be made with the "grounds" with riveted joints. Copper conductors give no better protection than iron if the iron is galvanized to prevent it from rusting.

All painted metal roofing and siding should be painted as soon as put on in order to cover up any metal that may have been exposed through scratches. High grade paints will be found economical in the long run, both from the standpoint of durability and the frequency of repainting.

Galvanized roofing and siding should be exposed to the atmosphere for about eight weeks before they are painted. This gives the slightly greasy surface of the galvanizing an opportunity to weather away, and a stronger foothold for the paint is thus secured on the surface of the zinc. It is unnecessary to paint galvanized material in clean, dry atmosphere, such as is encountered in the South, Southwest and Northwest.

The accompanying illustrations show a number of farm buildings on which sheet metal has been successfully and economically used and are presented through the courtesy of the Milwaukee Corrugating Co., Milwaukee, Wis., and the Inland Steel Co., Chicago, Ill. The latter company has for some time past been preparing an excellent book on the value of sheet metal on farm buildings, and its publication has only been delayed by the condition of the galvanized sheet market.

MEANING OF "FIREPROOF CONSTRUCTION"

Much discussion has occurred in the past as to what constitutes real "fireproof construction," and in order to give a clear definition of what is meant in the law by this term when reference is made to factory buildings, the Labor Law of New York was

A GOOD EXAMPLE OF THE USE OF SHEET METAL IN FARM BUILDINGS CONSTRUCTION

amended by the last Legislature. The section relating to this matter now reads as follows:

1. *Fireproof construction.*—A building shall be deemed to be of fireproof construction if it conforms to

the following requirements: All walls constructed of brick, stone, concrete, or terra cotta; all floors and roofs of brick, terra cotta or reinforced concrete placed between steel or reinforced concrete beams and girders; all the steel entering into the structural parts encased in at least 2 in. of fireproof material, excepting the wall columns, which must be encased in at least 8 in. of masonry on the outside and 4 in. on the inside; all stair wells, elevator wells, public hallways and corridors inclosed by fireproof partitions; all doors, fireproof; all stairways, landings, hallways and other floor surfaces of incombustible material; no woodwork or other combustible material used in any partition, furring, ceiling or floor; and all window frames, doors and sash, trim and other interior finish of incombustible material; all windows shall be fireproof windows except that in buildings under 70 ft. in height fireproof windows are required only when within 30 ft. of another building or opening on a court or space less than 30 ft. wide, and except further that any window not within 30 ft. in a direct line of another building not in the same vertical plane, nor opening on a court or space less than 30 ft. wide, nor within 50 ft. in a vertical direction above the roof of a building within 30 ft., may be provided with plate glass not less than one-fourth of an inch in thickness, no light of which shall exceed 720 sq. in. in area; except that in buildings under 150 ft. in height there may be wooden sleepers and floor finish and wooden trim, and except that in buildings under 150 ft. in height heretofore constructed there may be wooden sleepers, floor finish and trim and the windows need not be fireproof windows, excepting when such windows are within 30 ft. of another building.

STRENGTH OF TREATED TIMBER

The result of some recent tests carried on by the Forest Service in order to determine if timber is weakened by preservative treatment is announced in Bulletin 286. The timbers tested were Southern yellow pine and Douglas fir, beams of large size being employed. Some of the results are stated to be as follows:

Timber may be very materially weakened by preservative processes.

Creosote in itself does not appear to weaken timber.

A preservative process which will seriously injure one timber may have little effect, or no effect, on the strength of another.

A comparison of the effect of a preservative process on the strength of different species should not be made unless it is the common or best adapted process for all the species compared.

The same treatment given to a timber of a particular species may have a different effect upon different pieces of that species, depending upon the form of the timber used, its size, and its condition at the time of treatment.

EMERGENCY MUD HOUSES FOR ENGLAND

The possibility of using mud as a building material and so solving the urgent problem of providing cheap country cottages in the rural districts of England and housing accommodation in the areas where there has been a sudden influx of war workers is being made the subject of an interesting experiment by the new household and social science department of King's College for Women, University of London, says a late issue of the *New York Sun*.

Six mysterious looking walls have just been erected in the grounds at Camden Hill, each wall being composed of a different mixture of mud, with a view to testing which proves most suitable to the English climate.

In each case the earth has been subjected to a different process of preparation. In one case water-glass has been added, in another soft soap and in another case lime has been added to the earth and soft soap. A "grouting" of cement has been poured over the mud in yet another case and there is one wall made of earth alone.

A MODERN CORN CRIB AND GRANARY

AN IMPORTANT ADJUNCT OF THE WELL-EQUIPPED FARM—THE CORN ELEVATOR

ONE of the more important buildings upon the well equipped farm located in corn growing sections is the crib and granary. As this structure is subjected to great internal pressure, a strong framework is essential, particularly in connection with the storage bins, if ultimate economy is to be secured. The building should be so constructed that it will keep the grain from spoiling and serve as a protection from mice and rats. Obviously the first essential of a good building for storing grain is a vermin proof floor upon a solid foundation. Another essential is that the spot on which the building is located be well drained. Concrete serves as an excellent material for the foundation and floor, not only by reason of its durability

but the cost for repairs is little or nothing. It is sanitary, vermin proof and easily constructed.

One of the illustrations presented herewith affords an excellent idea of the framework for a building of this kind measuring 26 x 40 ft. Carpenters and builders have well defined ideas of their own as to the framing and construction of corn cribs, but if they prefer a more substantial bracing than that indicated, they can add a 2 x 10 in. brace running crosswise on the crib, which can be bolted or nailed to the cross braces shown in the drawings. These can be used every 4 ft. or for every other studding. The floor plan shows the general layout with the concrete driveway extending into the crib as far as the pit into which the corn

is dumped before being transferred to the bins on either side.

The foundation is made of concrete mixed in the proportion of one part cement to six parts gravel.

is installed. It may be operated by horse power or engine, according to convenience, and it will be noted that the section that carries the filled cups is enclosed on all sides so that no grain can be spilled or lost. The conveyor folds between the carriers of the elevator.

The corn crib and granary here shown is equipped with Meyers upright cup elevator made by A. F. Meyers Manufacturing Company, Morton, Illinois, and the drawings so clearly indicate the general construction and arrangement that extended description would seem unnecessary.

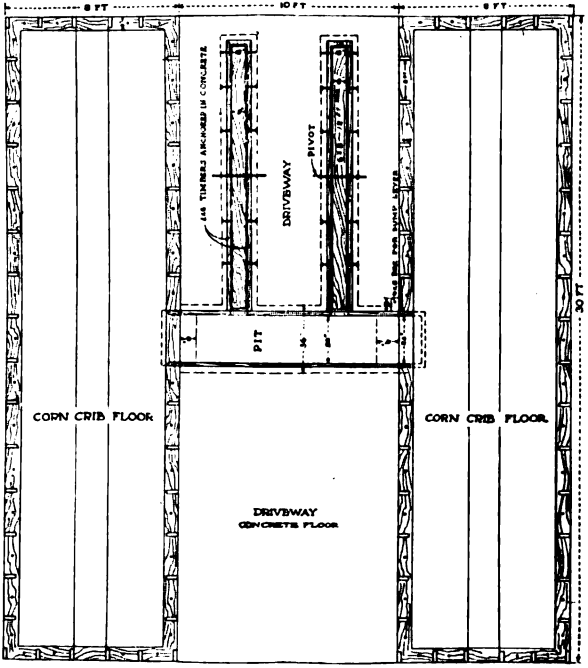

Perspective of Framing for a Corn Crib 26 x 40 Ft. in Plan

TALLEST SCHOOLHOUSE
IN NEW YORK CITY

What will be the tallest public school building in the city of New York is now in course of construction at the corner of Lexington Avenue and Twenty-second Street in accordance with plans prepared by C. B. J. Snyder, architect of the Board of Education. It is intended for use as the "Manhattan Trade School for Girls," will be ten stories high and constructed of limestone, terra cotta and brick. The foundations present a rather interesting engineering problem,

Vertical Cross Section of Corn Crib, Showing Elevator Installation

Floor Plan Showing Driveway, Corn Pit and Position of Elevator

An important feature of the corn crib is the elevator, and for greater economy the building should be comparatively high. The vertical cross section of the crib shows the manner in which the elevator

for the reason that forty feet below the surface of the site is an old river bed. It is estimated that the structure will cost about \$480,000.

NEW PUBLICATIONS

New Homes Under Old Roofs. By Joseph S. Seabury. Size 12½ by 9½ in. Illustrated by 75 art prints. Bound in cloth. Published by Frederick A. Stokes Co. Price \$3.50 net.

Of recent years a wave of appreciation for the work of our forefathers has swept over the country and many are the attempts to save architectural gems of Colonial days from the resistless hand of time. Nowhere is this patriotic effort felt more than in the field of restoration and remodeling of old Colonial homesteads. In most cases, the work is one of love, and no pains are spared to make the restoration true to the epoch and ideals of the historic past.

The book under review is a volume constructed along lines that permit of an excellent idea of just what can be accomplished by a skilled architect along lines of exterior restoration. There are thirty-six examples given, the house "before" and "after" being pictured on facing pages. The illustrations are nearly three-quarter page size and a short caption points out the means by which the transformation was effected. An introductory chapter contains interesting information concerning the development and arrangement of the types of plans usually found in Colonial residence construction. The work is such as to convey a fund of information to all interested in the restoration and remodeling of beautiful houses of the past.

Fire Prevention and Fire Protection for Hospitals.

By Otto R. Eichel, M.D. 69 pages, size 5 x 7½ in. Bound in cloth. Published by John Wiley & Sons, Inc. Price \$1.00.

There is hardly any class of buildings in which the fire hazard is more to be dreaded than in hospitals. The book under review aims to afford a knowledge of adequate facilities for the protection of this class of structure and provides in convenient form an outline of the principles of fire prevention and protection with indications for their application in institutions housing the sick. It is planned to meet the requirements of architects, builders, superintendents and boards of managers, inspectors and others who may be interested in the subject. Hazards due to lighting, heating, etc., together with chemical extinguishers and similar appliances are considered. The author has had many opportunities to acquaint himself with the best practice along these lines, due to his activities as Director of the Division of Sanitary Supervision, New York State Department of Health.

The Stability of Arches. By Ernest H. Sprague, A. M. Inst. C. E. 150 pages, size 5 x 7½ in. Illustrated. Board covers. Published by Scott, Greenwood & Son, London. American Agents, D. Van Nostrand Co. Price \$1.25.

The scientific treatment of the subject of arches first began early in the eighteenth century. Previous to that time the general condition of me-

chanical science was not such as to permit of the scientific study of the subject and arches were constructed by builders who drew upon practical knowledge and personal experience, traveling from place to place as need for their services arose.

Whether the arch be regarded from its old artistic or newer scientific side, the beauty of its form and the combined lightness and strength of its construction make the subject one of interest to many. The book under review, which is one of the "Broadway Series of Engineering Handbooks," is written by a man thoroughly familiar with his subject. Illustrations consist of five folding plates and fifty-eight diagrams, which, together with the numerous formulae and accompanying illuminating descriptions, can not fail to prove of value to the architect and the builder interested in the subject.

The chapter headings include "The Three-Pinned Arch," "Elastic Theory of the Arch," "The Two-Hinged Arch," "The Hingeless Arch," "Masonry and Concrete Arches," "Design of Masonry and Concrete Arches," "Loads and Stresses," etc., together with an appendix which gives methods used for the calculation of the ordinates of a circular arc.

COURSE IN CONCRETE WORK AT WENTWORTH INSTITUTE

As mentioned a short time ago in these columns, the Wentworth Institute of Boston has just added to its curriculum a course of instruction in concrete work, the idea being to train young men for the position of concrete foremen and contractors. The institute has set aside one of its best laboratory rooms and is fitting it up with modern testing machinery and other necessary equipment in order to make possible various determinations which will illustrate the technical as well as the practical sides of the applications of concrete.

This work, we understand, has been made possible largely by the co-operation of the Extension Division of the Portland Cement Association. We understand that J. C. Donaldson, Field Engineer of the Extension Division, will be located at Wentworth Institute for some time assisting in starting and directing the course in concrete along the lines planned. This departure is, in a sense, new for an institution of the class in which Wentworth Institute may justly be placed, yet is only an extension of the Manual Training in concrete idea which has demonstrated its popularity and appeal in numerous ways during the past year or more. This was most notable, perhaps, in the recent short course in concrete for manual training and vocational teachers which was held during the early part of the summer at Lewis Institute, Chicago, and reference to which appeared in these columns at the time.

Proper ventilation of residences is a phase of building construction deserving of much more attention than it often receives.

CURRENT NEWS OF BUILDERS' EXCHANGES

ANNUAL MEETINGS — OUTINGS — NEW QUARTERS AND MEMBERSHIP CAMPAIGN

Annual Outing of Cleveland Builders' Exchange

THE annual fall outing and dinner of The Builders' Exchange of Cleveland, Ohio, was held in September. Over 250 members, together with a number of architects and other guests, made the affair the largest attended ever given by the Exchange. The afternoon was devoted to various sports, great interest centering in the baseball game between the contractors and the supply men, the latter winning by the healthy score of 30 to 8.

At a membership lunch held on Sept. 25, E. M. Craig, secretary-manager of the Chicago Construction Employers' Association, made an interesting address on the subject of organization among contractors and other employers in the building trades, his remarks being especially timely owing to the recent formation of such an organization under the auspices of the Exchange.

Fiftieth Anniversary of Buffalo Exchange

The fiftieth anniversary of the Builders' Association Exchange of Buffalo, N. Y., will be held in January, 1917, and as the New York State Association of Builders is to hold its next annual meeting in that city, the two events will fit in together nicely.

Secretary F. N. Farrar states that local business in the building trades is improving, and he expects early easement of labor conditions, due to the suspension of various municipal activities.

Annual Meeting of Wisconsin Master Builders

The Builders' and Traders' Exchange of Oshkosh, Wis., is making extensive preparations for the annual meeting of the Master Builders' Association of Wisconsin, which is to be held in Oshkosh from Jan. 10 to 13, 1917. At the September meeting of the local organization a committee was chosen consisting of E. E. Beals, E. L. Mundin, Matthew Mertz, August Pitz, L. W. Dukerschein, E. E. Meelens and O. A. Toner. Each of these committeemen heads a sub-committee which will devote itself to some one phase of the entertainment.

It is planned to organize special visiting parties to the local plants which manufacture building materials, so that the builders may familiarize themselves with the materials manufactured in Oshkosh.

A vote of thanks for his efficient services during the past five years was tendered to Secretary and Treasurer John Edwards, who presented his resignation at the meeting. E. L. Mundin was elected to fill the vacancy.

New Home of Minneapolis Builders' Exchange

That the Builders' Exchange of Minneapolis is in the progressive ranks of such organizations is evidenced by the activity which it has displayed in bringing to a successful completion the movement for a building of its own. The preliminary plans for a twelve-story structure with a terra cotta and press brick front have been drawn by Bertrand & Chamberlin, associated architects, and received the unanimous approval of the members at a meeting held on Oct. 3.

The building is to be located on Second Avenue South, in the business section of Minneapolis, and there is every indication that the property will substantially increase in value. The site of 75 x 132 ft. has been leased for 100 years, with the option of purchase any

time within 10 years. Although no effort has as yet been made to secure tenants, five floors have already been taken.

The ground floor is to be devoted to a permanent exhibit of building materials. On the top floor there will be a spacious assembly room, the intervening floors being devoted to offices.

The funds for the project, which is estimated to cost over \$250,000, have practically been subscribed by members, and no doubt is expressed but what the investment will be a good one. Much credit is due to the indefatigable efforts of the temporary building committee, which consists of Chairman E. E. Leighton, George Beldon, E. G. Evensta, William Penn, Eugene Young, W. A. Elliot, James Teck, N. W. Nelson and M. Schumacher.

A meeting of the stockholders is scheduled for Jan. 1 for the purpose of electing officers for the ensuing year.

Membership Campaign of the Philadelphia Exchange

The Builders' Exchange of Philadelphia, Pa., held its quarterly meeting on Sept. 26 and much appreciation was expressed for the success of the membership campaign inaugurated last spring. That the organization is a live one is evidenced by its determining not to rest on the laurels already gained, for it has been decided to offer a first and second prize of \$50 and \$25 respectively in gold in order to spur on the men in a competition to find out who are the two best membership getters during the year. To be eligible for the first prize, a member must secure ten or more enrollments, and to be eligible for the second prize, five or more. Every member was urged to bring friends eligible to membership to the weekly luncheons, which began Oct. 10, and to hand a list of such eligibles to the membership committee.

Buffet Luncheon and Vaudeville by Chicago Builders' and Traders' Exchange

"Don't let a previous engagement keep you from attending the big stag, cabaret and buffet luncheon on Thursday, October 12," was a message received by members of the Builders and Traders Exchange of Chicago a few days prior to this event. The announcement was also displayed in large letters on the Bulletin Board in the rooms of the organization, with the result that a crowd approximating two hundred turned out to participate in the festivities. The suite of rooms on the second floor of the Chamber of Commerce Building were comfortably packed from 4 o'clock on, the members taking the opportunity to renew business acquaintanceships and to make new friends in the building field. Secretary Joe Hendricks had his hands full, for he presided over a long table that was laden down with good things to eat. His invitation to "dig in" needed no second call. In the meantime, a piano furnished music and popular songs were sung by a group of the younger members of the exchange.

At 6 o'clock the cabaret and vaudeville entertainment was staged and amusements continued until 9 o'clock. The affair was informal, and most successful. During the day the officers were present to greet new and prospective members, while several members of the Builders' Club attended, as did Secretary Craig of the Building Construction Employers' Association. Meetings of this character are responsible for the establishment of closer and more cordial business relations among the members, and their popularity is an indication.

BRIEF REVIEW OF THE BUILDING SITUATION

BUILDING OPERATIONS FOR SEPTEMBER SHOW 5¼ PER CENT INCREASE OVER SEPTEMBER, 1915

ARATHER more gratifying situation in the building industry in September is evidenced by the reports which reach us from 128 cities of the country. The notable gains are found in the middle and extreme western sections, while in the East there is a somewhat lessened activity as compared with this period last year. This decrease in the value of projected buildings is due in large measure to the lull in some of the leading cities, notable shrinkages appearing in Philadelphia, Pittsburgh, New Haven, Trenton, Hartford, Bridgeport, Albany and in four of the five leading boroughs constituting Greater New York. The 46 Eastern cities reporting show a loss of 9.22 per cent as compared with September last year.

CITIES OF EASTERN STATES

	Sept., 1916	Sept., 1915
Albany	215,555	340,965

"BIG 4"

The **Acknowledged Superior of all Barn Door Hangers**

The "BIG 4" stands pre-eminent among builders and thousands of dozen pairs are giving the most satisfactory service under severe conditions in every section of the country.

INSURE YOUR CUSTOMER'S INTERESTS

by building for permanence. You can only do this by installing a hanger built on extremely heavy lines and without complicated parts to get out of order.

The "BIG 4" Hanger is made entirely of steel. Supplied with anti-friction steel roller bearings, giving a perfectly free motion to the door.

Our catalogue gives detailed information.

Buy Your Material WHOLESALE Add to Your Profits

All the material for the above house complete at \$789 is only a sample of 300 other equal house bargains in our 2 Big Plan Books—both FREE to you. Every contractor and builder should have these books. You can make money by having our Contractors' Service Bureau working for you. It is already increasing profits for over 10,000 other Carpenters and Builders in every state. It is furnishing free "Guaranteed Right Estimates." It is assuring prompt deliveries, cutting out lost time and labor costs. It is drawing plans for them—far cheaper than local architects could. And it is doing other things. Make the Gordon-Van Tine Expert Service Department work for you. Buy the material for your houses on our wholesale "mill-to-you" prices. Get plans Free! It is profitable for you to pay about 3½% for freight and to save 25% to 50% on your bill.

3 Big Books—FREE!

Also get our free 156 page, illustrated Bargain Catalog. Describes and pictures over 5000 bargains in Lumber, Millwork, Builders' Hardware, Glass, Paints, Roofing, Wall Board, Doors, Windows, Porches, Stairwork, Flooring, Shingles, Nails, Enamel and many other money-savers! Costs you nothing to get this Great Book! Free. Let it make prices for you. Write our Service Bureau at the same time for any information or assistance you want. No charge—yours for the asking

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

Asbestos Shingles for Farm Barns

In buying roofing to-day the farmer has much more to consider than ever before. He has more varieties to choose from than formerly. But what he is looking for is a permanent roofing that will give lasting satisfaction. He is willing to pay a good price for such a roofing, in return for which he asks fire protection, sightliness, freedom from maintenance expense, and a low cost per year.

To meet all requirements in the demand for more durable safer materials, asbestos is being developed as a roof covering material for use on all types of farm

these shingles, but, on the contrary, the claim is made that they actually grow stronger in service.

For farm buildings with sloping roofs that require a more moderate-priced roofing than the shingles, asbestos roofings of the ready roll type have been introduced. These roofings are made of asbestos rock fiber, felted into pliable sheets which retain all the rock-like characteristics of the original mineral. To make this waterproofing waterproof and unaffected by weather, these asbestos sheets are thoroughly saturated with natural asphalt, and asphalt is again used as a cement between the plies. Due to this construction, such a

Fig. 1—A Good Example of Round Barn Roofed with "Transite" Asbestos Shingles

buildings. Principal among these asbestos types are asbestos shingles and roofings in "ready roll" form. For farm residences and high-grade farm buildings the asbestos shingle is peculiarly fitted, since it has architectural decorative possibilities found in a unique range of sizes, shapes and colors, in addition to the necessary qualifications of durability and fire protection. Furthermore, it is so constructed that it may safely be termed indestructible. Asbestos shingles are made of asbestos rock fiber and Portland cement and compressed under hydraulic pressure, the finished product proving to be an all-stone material that will endure the contraction, and expansion of heat and cold without cracking. It is said that age does not weaken

roofing carries the assurance that when it is once in place there will be no necessity of frequent painting to keep the material from rotting, cracking, drying out, and eventually developing leaks to require patching. It is essential to note that both the shingles and the roofing of the "ready roll" type are fire-resisting. These roofings are inspected, approved and labeled by the Underwriters' Laboratories, Inc., under direction of the National Board of Fire Underwriters.

The efficiency of a good roof, however, is not always dependent on the material alone. The method of laying has a great deal to do with the service the roof will give. This is particularly true of roll roofings. The commonly used "nail-and-cement-it" method of ap-

plying roll roofing will give a good roof under most conditions, but it obviously allows the laps of the roofing to be its weakest point.

This disadvantage, coupled with the smeary and spattered appearance of roofing laid with cement, has led to the perfection of a roofing cleat known as the Johns-Manville Vise-Grip Cleat, which is a strip of galvanized metal nailed on at the laps, in place of the old method of using cement or tin caps and nails. Laid with J-M Vise-Grip Cleats, the lap joints of roofing are literally welded together, forming a secure, waterproof roof. J-M Cleats, by reason of their specially designed shape, exert a strong, continuous gripping pressure along the whole length of the lap. The roofing cannot pull away from their tenacious bulldog grip. For when the roofing pulls and wrenches, the grip of the metal exerts an even, positive pressure that does not relax. The J-M Cleat forms a neat beading, which adds in every respect to the appearance of the roof. The Cleats are supplied with every roll of J-M Asbestos Roofing and J-M Regal Roofing, when ordered.

In Fig. 1 is illustrated a good example of Johns-Manville Transite Asbestos Shingles on a round barn for the farm.

Barn Roofed with "Rex-Tile" Asphalt Shingles

The farmer has the reputation of being a shrewd buyer of materials and equipment that will reduce his maintenance costs, and he has accepted asphalt shingles

contractor appreciates the simplicity with which they are put on, and can assure the owner that the first cost covers his entire roofing expense.

Modern Stable Equipment

One of the most important problems in connection with an up-to-date farm is how to obtain thoroughly sanitary and comfortable quarters for the live stock at a minimum of care and labor. Litter carriers, ensilage carriers, merchandise carriers and hoists, etc., all aid considerably in facilitating the transportation problems of the farmer, and these contrivances are illustrated and described in "Modern Stable Equipment," issued by the Glor Bros. & Willis Mfg. Co., Attica, N. Y. These systems, of course, depend greatly upon the track for their efficiency and therefore track and switch construction, together with the manner of installation, are illustrated and described. Information is also given in regard to sanitary steel or wooden cow stalls of various kinds, end guards, stall guards, adjustable steel gates, manger partitions, watering bowls and systems, calf and bull pens, stock pens, piggeries, hog troughs, Buckeye ventilators, spiral stairs, cork brick, etc., for stable floors, as well as other matters calculated to be of interest. The majority of the foregoing are accompanied by instructions for installation, and all are illustrated. The company states that its interest does not end with the selling, but continues until the ap-

Fig. 2—Dairy Barn and Silos at Spring Brook Farms, Preakness, N. J., and roofed with "Rex-Tile" asphalt shingles

with the confidence that they make an efficient roof that costs less in the long run. The fire-resisting qualities are of vital importance to the farmer, who usually has no fire-fighting system, for asphalt shingles will save a building if sparks should fall on it from a nearby fire. The Asphalt Shingle Publicity Bureau, 954 Marquette Building, Chicago, Ill., believes that the contractor who is constructing farm buildings has good reason to specify asphalt shingles because they will have a quick appeal to the farmer's judgment. They are made of asphalt and crushed stone, while permanency of color is assured because of the fact that the colors are produced from the rock itself. Their beauty and harmony are illustrated on the dairy barn and silos at Spring Brook Farms, Preakness, N. J., shown in Fig. 2, and which are covered with "Rex-Tile" asphalt shingles, made by the Flintkote Mfg. Co., 98 Pearl Street, Boston, Mass. The owner has every reason to feel proud of appearances in this instance, for the shingles add just that touch of color that does so much toward brightening and enhancing the group of buildings. Many prominent stock farms are using asphalt shingles on their enormous barns where the amount of material involved makes it well worth while to study efficiency. On silos they are especially applicable in that they can be bent or made to fit the curve of the roof so easily. The

paratus is installed, furnishing full descriptions when desired as an aid thereto, or attending to the installation direct as may be preferred.

Globe Ventilators for Farm Barns

That proper ventilation of farm buildings is essential and, in the end, economical, is evidenced by the increasing attention given this important subject by progressive farmers. A type of ventilator which is said to give great satisfaction is that made by the Globe Ventilator Co., 205 River Street, Troy, N. Y. Among the many barns equipped with Globe ventilators mention may be made of those of the State of Vermont Experimental Station at Lyndonville. The first order was given in 1900 for two 24-in. ventilators, and since then, as new buildings have been erected, the company has received re-orders so that at present it has furnished a total of twelve 24-in. and one 30-in. Globe ventilators for the barns in question. Another prominent user of this type of ventilator is the Oconomowoc Farms, which purchased four 30-in., four 15-in., three 12-in. and two 8-in. ventilators, the smaller sizes being intended for the milk house. For its farm at Chilton, Wis., use

THE SENIOR ARCHITECT'S STORY

CLINTON WIRE LATH

"YES, I DISTINCTLY REMEMBER THE DAY I FIRST saw *Clinton Wire Lath*. It was before the Rebellion. I was watching the men at work on a big hotel and noticed that they were using some kind of strange material in place of the usual wooden lath. I found out that it was the then new *Clinton Wire Lath*. I got a sample and brought it up to the architect's office where I was learning the business."

"I am the senior partner of that firm now, and since then—over half a century ago—my firm has specified *Clinton Wire Lath* for all plaster and stucco support."

Send for our profusely illustrated book, "Successful Stucco Houses;" also "Clinton Handbook on Lath and Plaster." Both mailed free.

Fig. 3—One of the Models of a Well Equipped Farm Exhibited by the Southern Pine Association at the "Exposition of a Reconstructed City" Held in Paris

was made of one 24-in. and two 8-in. ventilators, while for the farm at Richland Center, Wis., it used one 24-in., two 26-in. and two 8-in. ventilators.

Model Farms of Southern Yellow Pine

An international reputation was acquired by Southern yellow pine this summer when two model farms, constructed for the Southern Pine Association, Kansas City, Mo., were exhibited at the Exposition of a Reconstructed City, held in Paris, France. The models, which are reproduced in Figs. 3 and 4, are excellent illustrations of the uses to which this wood can be put and the artistic beauty obtained where this material enters in the construction. It is said that on account of its extensive use on American farms it has gained the name of the farmer's wood, and has always met with every farm building need. The wood can be used for all types of buildings and occupies a position of importance in every kind of heavy construction for trusses, beams, joists, rafters, sills—wherever strength and endurance are essential.

The Government Forest Service made an exhaustive and painstaking study of the most important of the commercial woods of this country, and the result of these tests, compiled in a series of comparative tables, pay tribute to the qualities of Southern yellow pine. It will be found desirable for interior finish, and is of uniformly high quality and gives maximum service at moderate cost. The wood is bright and attractive in color. While remarkable strength, stiffness and toughness are qualities that contribute to the endurance of Southern yellow pine, its longevity is due in a great measure to its peculiar structure, and the resin and wood oil, natural preservatives, with which it is impregnated. Its grain is dense, close and even, hardening with age. This

wood has been used to a considerable extent for constructing silos, and some of the oldest in existence are built of this material, while its availability and easy working nature make it an ideal all-purpose wood for farm building construction.

The models here shown were made by Fred Wilhelm of 505 West Dayton Street, Madison, Wis.

A Book of Loudon Barn Plans

Through the courtesy of the Loudon Machinery Co., Fairfield, Iowa, we have received a copy of what is one of the finest catalogs devoted exclusively to barn building design and equipment ever issued by a manufacturer. It has been published by the company's architectural department with a view to assisting its clients to meet their requirements by economical construction and to suggest means of solving problems that come up in connection with proper lighting, heating, ventilation, drainage, disposal of manure, and other sanitary and hygienic problems, as well as the protection against weather exposure and fire risk. There are more than fifty plans of dairy barns, horse barns, hog barns and buildings of a miscellaneous character, each of which is illustrated, showing an exterior view and floor plan, accompanied by a short sketch of the dimensions, capacity and estimated cost, each building being designed for a specific purpose. The index at the back enables the contractor to locate the building that will fill his requirements, and should he fail to find just what he wants, the company's staff stands ready to render assistance that will combine utility and sanitation with economy and strength in the construction. The book has 112 pages, many of which are devoted to detail drawings. A volume double the thickness of the barn book is General Catalog No. 43, devoted to a wide

Fig. 4—Another Model of a Well Equipped American Farm Exhibited by the Southern Pine Association

variety of hay unloading tools, barn and garage door hangers, litter, feed, merchandise and milk can carriers, stable equipment, cupolas, ventilators, drains and hardware specialties. The company has branch offices in St. Paul, Minn., Albany, N. Y., Fort Wayne, Ind., Kansas City, Mo., and Guelph, Ont.

"A Spark May Cost a Farm"

Under the above title there is being distributed among architects and builders throughout the country by the Keasbey & Mattison Company, Ambler, Pa., a very attractively printed publication of twenty-two pages, profusely illustrated with half-tone engravings, showing farm buildings of various kinds, in connection with all of which use has been made of Ambler asbestos shingles of the "Century" brand. The application of the title above is found in the fact that a spark on the roof of a building with a light wind—just brisk enough to fan the leaves on the trees—may cost the destruction of all the buildings on a farm, and from this the lesson is derived that all farm buildings should have their roofs covered with shingles which will not burn.

It is pointed out that the "Century" brand of asbestos shingles are made from cement and pure asbestos fiber, and are therefore practically indestructible. They

Hydrated Lime in Concrete

Hydrated lime as a part of concrete has many virtues claimed for it. The United States Bureau of Standards states that in a test comprising forty waterproofing materials, hydrated lime proved to be the most efficient. It is said to increase the plasticity of the mix, to minimize the danger of honeycombing, aids to secure a better mix of the material and increases the slipperiness of the material so that it flows freely without the use of excessive water. These advantages of hydrated lime are set forth in Bulletin A-2 entitled, "Dependable Concrete," which can be secured by any reader of THE BUILDING AGE upon application to the Hydrated Lime Bureau of the National Lime Manufacturers Association, Arrott Bldg., Pittsburgh, Pa.

Fire Resisting Test of Fenestra Windows

At a recent meeting of the New York State Industrial Commission it placed its stamp of approval on Fenestra solid steel windows as a fireproof window meeting all the requirements of the Industrial Code. This action of the commission was based on the result of a fire test in which three standard Fenestra windows joined by mullions were subjected to a temperature of 1600 deg. for a period of 63 min. and then immediately

"A Spark May Cost a Farm"—Fig. 5—View of Buildings on Good Hold Farm Roofed with "Century" Asbestos Shingles

give the advantage of concrete construction with the additional fire protection assured by the asbestos fibers, and the claim is put forth that these shingles are not affected by extremes of climatic changes.

The striking feature of the publication referred to is the cover design, printed in colors and showing the main group of buildings on the Good Hold Farm, near Mentor, Ohio. The horse barn appears in the foreground, while at the left is the driveway to the office, the creamery, the cow barn, wagon shed, calf and feed barn, celery and hen house, farm implement shed, etc. The photographic reproduction of this group of buildings is here presented in Fig. 5. All the buildings are covered with Ambler asbestos shingles of the "Century" brand. The horse barn in the foreground is 66 ft. wide, 96 ft. long and 85 ft. high. It has thirty-six stalls and three harness rooms and a capacity for 250 tons of hay. It is equipped with such conveniences as cement stalls, cement troughs with cleaning slip, drainage, and four grain shutles holding 1000 bu. each. In the group shown are four cow barns, two being 40 x 100 ft., one 40 x 184 ft. and one 40 x 160 ft.; two dairy barns 40 x 80 ft. and 34 x 120 ft.; one storage barn 40 x 80 ft. and an implement barn 40 x 180 ft., the front portion of which is used for tractor engines, and the back contains bins for 9000 bu. of corn. The three piggeries have accommodations for 250 pigs, the five silos have a total capacity of 900 tons and the chicken house measures 40 x 200 ft. in plan.

subjected to a stream of cold water under pressure. The test, which was conducted by Prof. James S. MacGregor at the Columbia University Fire Testing Station, was designed to prove that solid steel windows of the Fenestra type would resist any degree of heat they might be called upon to meet in an ordinary fire. In the course of Professor MacGregor's report the statement was made that, "After the test all three vents of the windows used were opened without difficulty and could be swung closed and locked with ease." The results of the test are of special interest to architects, building owners and to the manufacturers as well, as a handicap is removed to the use of such windows, especially in the State of New York. An old state law practically limited the sale of solid steel windows to units not exceeding 5 ft. wide and 9 ft. high. The demand of manufacturers and owners of buildings, however, was for a steel window such as Fenestra that could be used singly or in combined units of practically any size needed.

"Pecky" Cypress

The advantages of cypress for certain purposes are well known, but "pecky" cypress has, perhaps, not received the attention it deserves. This is the heart wood of the tree and is taken from trees which have been attacked by a certain fungus, which enters from the top of

Bath room beauty

KOHLER Bath Tubs are chosen for the finest hotels and apartment buildings, such as the Edgewater Beach Hotel, Chicago.

This is because of the unequalled beauty and excellence of

KOHLER WARE

—Always of one quality—the highest

But it is not for the very high-class buildings only that KOHLER Bath Tubs, Lavatories and Sinks are most suitable.

KOHLER WARE, with its hygienic designs and purest white enamel, is in wide and rapidly increasing demand for the less expensive houses, apartments and bungalows.

The permanent trade-mark "KOHLER," to be found in faint blue in the enamel of every KOHLER Bath Tub, Lavatory and Sink, is our guarantee of excellence.

Builders will find that KOHLER products are designed to make installation easy.

the tree and attacks only the heart wood. It flourishes for a time, but soon a counteraction is set up which results in the infiltration of a portion of the wood with curious chemical substances, which give the pecky wood peculiar qualities. These chemical substances are in the nature of a defense evolved by the tree and kill or destroy the fungus. The substances permeate the wood and, being permanent, are said to resist all future attacks which may be made upon the wood. The result is visible in the holes and the process might well be called a tree vaccination. "Pecky" cypress is not as strong as the unattacked wood, but it is said to possess a strength amply sufficient for ordinary purposes. It is especially desirable for places where a timber with great immunity to rot is needed and as such is very valuable. Halftone engravings of its use in dwellings are contained in volume 2 of the Cypress Pocket Library entitled "Pecky Cypress," issued by the Southern Cypress Manufacturers' Association, New Orleans, La. In addition is a reprint of an authoritative article by Dr. Hermann von Schrenk, the well-known timber engineer, on "Pecky Cypress, Its Nature and Uses," together with other information and illustrations.

Proposition of Union Carbide Co.

Coincident with the manufacture of reliable generators, acetylene, as an illuminant and for cooking purposes, has made itself of value to the 250,000 homes in which it is now being used. With the idea of extending the use of this valuable illuminant and securing the installation of apparatus which are claimed to give satisfactory service, the Union Carbide Sales Co. Dept. 29, Forty-second Street Building, New York City, is urging carpenters and builders to interest themselves in pushing the sale of approved generators. The company is not in any way financially interested in the sale of apparatus, but confines itself solely to the manufacture and sale of Union carbide, and is prepared to refer interested persons to manufacturers of apparatus. This interest is said not to necessitate any investment or carrying of stock, but might be limited to furnishing the names of prospective users to any of the manufacturers who will be glad to make a proposition in respect to this. The company is distributing two illustrated booklets, "Sunlight-on-Tap" and "Artificial Sunlight," in which the growth and merits of acetylene as an illuminant are set forth. The metal package in which the carbide is supplied is shown in Fig. 6.

Fig. 6—A Moisture-proof Metal Package of Union Carbide

Ordering Fly Screens in Advance

It is probably safe to say that there is not a screen factory of any importance in the country that is not obliged to refuse good orders for screens each spring; neither is there a screen factory which is not hurried and worried in trying to take care of its business during the spring rush. As a result of this there are tardy deliveries, disappointed customers, hurried work, less durable screens and higher cost. In order to avoid this disagreeable condition of things, fly screens should be ordered in the fall or early winter for spring delivery. Every manufacturer gives preference to the customer who orders this way. If there are any concessions in prices or preference in materials, this is the customer who is most apt to secure them. Each coat of paint has ample time in which to dry, there is opportunity for careful work, a rigid inspection, and shipment is made at the usual time in the spring. In this connection it is interesting to note that the Standard Screen Company, 1848-58 Hastings Street, Chicago, Ill., has one of the largest and best equipped factories in the West, devoted entirely to made-to-order screen work. On account of the extensive equipment necessary and the output of the factory which we understand amounts to nearly a half million screens a year, the company is in

(Continued on page 86)

Endurance!

The quality demanded first and foremost in a roof is *endurance*.

The roofs you build must endure extremes of heat and cold. They must endure long spells of drought, of rain. They must endure—without deteriorating—a constantly varied attack for *years of service*.

It's sound business to put endurance into the roof of a house. A lasting roof is *your* lasting advertisement. That's why thousands of builders are *building their own reputation* by roofing with

The Wheel of a STERLING WHEELBARROW and its Pre-Lubricated Bearings

When all's said and done, the difference between a good wheelbarrow and a poor one is mainly in the wheel and its bearings.

In making the Sterling Wheel we first upset the shouldered Steel spokes into the heavy steel rim, as shown in Fig. 1.

Then the long sleeved steel hub is set into a special shaped mold, and molten iron is poured into the mold, cementing spokes and hub into one solid piece, as shown below in Fig. 4.

The steel sleeve of the hub is fitted with pre-lubricated fiber bushings, as shown in Fig. 2.

These bushings are filled with a composition of oils which thoroughly penetrate the pores. The bushings are then driven into the hub under great pressure. The longer the cold drawn steel axle turns in these bushings the smoother they become, and they never require oiling.

This bushed hub revolves round the axle. Note that it fits into recesses in the end-brackets (see Fig. 3). This construction affords valuable protection against sand and dirt.

The axle is cold drawn steel. See how it is keyed to the end-brackets with cotter pins, and how the malleable brackets themselves are secured to the bottom of the nose-end of the handles. There are no nuts to work loose; no side play; nothing to get the "rickets."

This is a real wheel, friends; built to last; a wheel that ensures light, noiseless traveling under the heaviest loads.

There are a lot of other exclusive features about the Sterling Wheelbarrow, but its wheel alone is enough to make the discriminating buyer give it a very decided preference.

Catalog of Stearns Hardware

An attractive "Catalog of Hardware" for 1917, bound in flexible cloth and containing a comprehensive index, has just been compiled by E. C. Stearns & Co., 400 Oneida Street, Syracuse, N. Y., and is being issued gratis to the trade. Of special interest is the floor scraper No. 10, which is intended for use on large surfaces and the merits of which were set forth in these columns some time ago. The catalog is profusely illustrated and most of the contrivances are described, prices, etc., of all being given. Other matters contained which will prove of undoubted interest and value to our readers are the various door locks and hinges, mitre boxes, saw vises and sets, door frame and concrete "form" clamps, cement workers' tools, etc.

Catalogs of Barn Equipment

A ventilating system will be found eminently successful where the equipment is designed especially for the conditions under which it is installed. The policy of the King Ventilating Co., Owatonna, Minn., is to make a study of the individual requirements and each system consists of three units—the King aerators on the roof, the foul air flues and the fresh air intakes. The practical methods followed by the company are explained in two illustrated booklets entitled, "The King Aerator" and "King Ventilating System for Creameries." Some interesting data is presented in demonstrating that the King system is scientifically correct and mechanically perfect, with particular attention given to the principles of ventilation.

"Make More Dairy Profits" is the title of an interesting catalog that is published by the West Bend Barn Equipment Co., West Bend, Wis. The company takes the stand that good standard barn equipment will reduce labor costs and add to the comforts of the herd. Work can be done in less time with West Bend automatic swinging stanchions, litter and feed carriers, because of their improved labor-saving devices. A line of individual watering foundations and governing tanks is made and other modern farm equipment.

The modern hay mow is not complete without the proper equipment to handle the hay quickly. The Strickler wide mouth swivel and reversible steel track carrier, grappling forks and structural accessories are made by the Strickler Hay Tool Co., Janesville, Wis., in addition to feed and litter carriers, stanchions, adjustable mangers, watering bowls, steel pens and stalls. These products are described and illustrated in three catalogs, any of which may be had on application.

Every practical dairyman knows that water in the dairy barn is as essential to producing good milk in the winter when the cattle are housed constantly in the barn as a spring of running water in the pasture. The F. Rassman Mfg. Co., Beaver Dam, Wis., manufactures the "Simplex" improved watering bowls that are sanitary and independent of every other bowl on the system. They are easy to clean, being hinged to drop, permitting a positive cleaning to the last settling. The bowls are 10 in. in diameter and operate on either gravity or pressure systems. Catalog No. 8 is evidence that the company's equipment is being specified for installation in modern barns.

An automatic litter carrier system that is practical, efficient and economical is made by the Drew Carrier Co., Waterloo, Wis. An interesting feature in this labor-saving device is made possible by the flexibility of the wire. When the carrier is loaded in the barn and shoved it will travel out of the barn clear to the end of the trolley, dump itself and return to the point where it started. The trolley wheels are equipped with noiseless roller bearings, and an improved stay-on keeper prevents the trolley wheel jumping the track. The carrier has galvanized steel bottoms, sides and ends, reinforced

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction is such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

We take pleasure in calling your attention to the construction of our "No Warp" Sanitary Doors, as illustrated above. They are made in the best manner, having cores formed of thoroughly seasoned laminated Chestnut stiles and rails, cross-framed and doweled together, and covered with 1-8 inch face veneers, and **WILL NOT WARP OR TWIST.**

We recommend them in all cases where sanitary doors are desired, and guarantee them for one year against defects due to the use of improper material or defective workmanship.

10 East 43d St.

Pittsburgh Office,
Liberty Bank Bldg.

FIREPLACE MATERIAL

A New Style Damper

This fireplace damper is made in both flat and dome styles. The lever sets under the first row of brick, unexposed, but very accessible and easily operated.

Also made with lower lever so a steel angle can be placed under edge of damper. We make several other style dampers.

Catalog 1590 shows these Dampers in detail and gives valuable suggestions as to the best construction for fireplaces.

Other Goods We Make

Cleanout Doors, Ash Trap Doors, Cast Chimney Thimbles, Brass Thresholds, Andirons, Fire Baskets, Fire Sets, Fire Screens, Spark Guards, Gas Logs, Door Knockers, Sink Brackets, Screen Door Hinges, Double Acting Hinges, Cast Iron Sash Pullers, Furnace Pulleys, Stove Pipe Registers, Dampers, Damper Clips, Saw Vices, Door Latches, Foot Scrapers, Chest Handles, Finish Rings, Harness Hooks, House Numbers, Door Pulls, Samson Wind Mills, Feed Mills, Alfalfa and Ensilage Cutters, Gasoline Engines.

by angles and malleable castings to give rigidity and strength. This is but one of the many products made by the company, all of which are carefully described and profusely illustrated in a 64-page catalog.

Hydraulic grain handling equipment is the specialty of Camp Bros. & Co., Washington, Ill., and the company is prepared to furnish hydraulic jacks, elevators with tilting and swinging hoppers, vertical or stationary cup elevators, portable elevators adjusted to the cupola in the roof, and conveyors. The company has issued literature which goes into minute detail of the numerous constructive features of all equipment and explanations are such as to leave nothing to the imagination.

The C. A. Libbey Co., Oshkosh, Wis., is one of the large makers of modern barn equipment in this country and operates a large two-story factory exclusively for this purpose. In addition to supplying all that is necessary for installation in dairy and stock barns, horse stables, etc., the company stands ready to serve its customers by making suggestions for the placing of stalls, pens, carrier systems, etc., in new or remodeled barns. This service is free and can be taken advantage of by the contractor who wishes his problems solved by experts with many years' experience.

The rural contractor's knowledge of modern barn equipment will be profitably augmented if he investigates the line manufactured by the Mitchell Mfg. Co., Milwaukee, Wis. A complete catalog of stanchions, cow stalls, carriers, pens, water and ventilating systems will be sent to contractors desiring information on a variety of products that can be used on the farm with economy and at a comparatively low initial cost.

Arkansas Soft Pine for Farm Use

A striking example of the durability and paint-holding qualities of Arkansas soft pine is to be found in the country town of Chatsworth, Ill., where the grain

Fig. 7—Use of Arkansas Soft Pine in Grain Elevator Construction

elevator, built in 1902, and shown in Fig. 7, is still in first-class condition. The Arkansas Soft Pine Bureau, Little Rock, Ark., contributes the interesting information that the building was sided with Arkansas soft pine and has been painted at reasonable intervals. The paint has never scaled or peeled, and has been renewed only when the action of the atmosphere and dust made it imperative. The bureau recommends this wood for constructing all types of farm buildings where dependability, economy and permanency are desired.

Stanley Mitre Boxes

are constructed on entirely novel lines and embody exclusive and important features not to be found in any other mitre box. They are thoroughly mechanical in design, have all parts made by jig and template, consequently interchangeable.

They are compact, strong and durable, are quickly and easily put together or taken apart for ease in carrying, have the greatest strength with the least weight, and will do the widest range of work of any mitre box made.

See Catalogue for complete details.

Manufactured by

STANLEY RULE & LEVEL CO.
NEW BRITAIN, CONN. U.S.A.

One of the features of Arkansas soft pine is that it contains a low percentage of rosin. It does not "gum" the carpenter's tools or power-driven saws, while its use on outside walls permits of the absorption of sufficient oil and pigment to bind paint to the surface. Because of the tough, resilient fiber of the wood, the tendency to split when nailed is reduced to the minimum, and the workable character of the wood makes the tightest knife joints possible—a factor that is vitally important in the construction of wind-resisting framework. The non-split feature is a further advantage when using this wood for roof sheathing, the tough fiber gripping the shingle nail tenaciously and insuring a securely fastened roof covering. The bureau has published many handsome pieces of literature on the numerous advantages of Arkansas soft pine, notably "Not a House, but a Home," "A Dependable Wood for Farm Use," and the "Architect's Manual," any of which may be had free of cost on application to the Bureau.

Parks New Combination Pony Planer

The increasing expense of lumber and labor renders machinery that will reduce these costs worthy of more than passing interest. Of the many devices designed to aid in the lowering of the cost of production one of the most recent possessing features of interest to the carpenter-contractor and builder is the combination machine which has been placed upon the market by the Parks Ball Bearing Machine Co., Station A, Cincinnati,

Fig. 8—Park's New Combination Pony Planer

Ohio, and a view of which is shown in Fig. 8. The jointer on this machine can be used the same as any other hand jointer, and by passing material back under the cutter head it is planed to the desired thickness. The planer attachment has self feed with two speeds. The planer head and circular saws are on separate mandrels, with friction clutches to start and stop independently of each other. The band saw has a belt shifter to start and stop independently. The moulder on the side of the machine has double heads so circular mouldings can be made by passing from one side to the other. It is said that sufficient power to run the machine can be furnished by a 5 h.p. engine or motor.

The Durability of California Redwood

The rot-resisting feature of California redwood is strikingly and attractively set forth in a folder just issued by Edwin E. Myers, secretary-manager of the California Redwood Association, the little folder being a companion to the one on fire retardance, which made its appearance several weeks ago. The California Redwood Association in its campaign to bring prominently to the attention of the consumers the merit of redwood, intends to use these two features, and it is admitted

Something For You

in our Pamphlet 29; viz.:

Valuable Tables for finding size of joist, safe load of joist, acuat load on hanger, etc., etc.

Some of these Tables are not in print elsewhere.

The Pamphlet and the Mounted Model Hanger will be mailed on request.

SOMETHING FOR US. We ask your special attention to items 5, 6, 7 on page 5 of the Pamphlet and to the matter on pages 23 and 24 relating thereto.

THE W. J. CLARK CO., Salem, Ohio, U. S. A.

that they have a battery of big guns of great power. The folder on rot resistance declares that the secret of the "Big Trees" of California is their defiance to rot and fire.

The folder is printed in color and carries on the cover a photographic reproduction of a redwood tree that lived 900 years as a fallen log in the woods. This tree was straddled by a redwood which, when cut down, was found to be 900 years old—indisputable evidence that the fallen giant had lain nearly 1000 years on the floor of the forest while there grew up around it another majestic redwood. The fallen tree by its rings shows it to have been 600 years old before it fell.

Large quantities of these folders on fire retardance and rot resistance of redwood are being distributed and copies will be sent to all who address Edwin E. Myers, Secretary-Manager of the Association, 711 Call Building, San Francisco, California.

Wallboard for Farm Buildings

Many and varied are the uses to which wall board has been put by reason of its wide adaptability, and the novel application of the material as a ceiling for the cow barn at the Green Acres Farm, Manchester, N. H., will doubtless interest many. As shown in Fig. 9, which represents a view down the main feedway, the joints of the wallboard are covered with battens, and it is said that the ceiling presents a smooth, sanitary surface. The makers of the wallboard shown in the picture are the Roberds Mfg. Co., 101 Spencer Avenue, Marion, Ind., who recommend "Ideal" wallboard for

Fig. 9—Wallboard for Farm Buildings

use in the construction of all sorts of farm buildings of the lighter types of construction. It is said that with a few 2 x 4's for framework and by the use of walboard, buildings can be quickly erected. The claim is made that wallboard can be used for both side walls and roof on the smaller type of buildings by keeping the surface of the board well painted.

The National Line of Builders' Hardware

The mass of detail that confronts the owner and contractor in the preparation of specifications for a new building is oft-times responsible for the acceptance of materials or equipment the merits of which have not been fully discussed. This is often true in connection with the smaller items entering into the construction. The question of using high grade hardware in the home, farm building or factory is very important, and the matter should not be dismissed by merely saying off-hand that anything will do. In this connection the contents of the 96-page catalog of the National Manufacturing Co., Sterling, Ill., will be found of interest. The contractor doing business in farming communities will find within its covers a fine selection of rigid barn door hangers, bumpers, latches, hinges, door pulls and other necessary hardware. The policy of the company, since its organization in 1901, has been to give its customers a better quality of goods and prompt shipment without substitution. In the construction, the company reports that only the best materials are used and finished prod-

ucts are turned out by expert workmen operating modern machinery. A complete stock of all items listed in the catalog is carried at all times and orders filled the day they are received. The company makes "hardware for hard wear" and invites correspondence from progressive contractors.

How to Set and File Saws

An attractive copyrighted pamphlet of 24 pages entitled "Saw Points" has just been issued by Charles Morrill, 102 Lafayette Street, New York City, N. Y. It is stated that the pamphlet is compiled from leading authorities and therefore illustrates the best saw practice of the day, the claim being made that by following the instructions given anyone can properly fit a saw. Numerous illustrations picture various bevels on the different kinds of saws and the matter contained is such as to appeal widely to those of the trade interested in saws.

Peerless Storm Sash Hanger

An improved form of storm sash hanger made of wrought steel, thus rendering it heavy and strong, has recently been added to the extensive line of storm sash hardware made by the Stanley Works, New Brit-

Fig. 10—Peerless Storm Sash Hanger

ain, Conn. The hanger is known as No. 1715, and views of it are presented in Fig. 10, one showing the hanger in place and the other showing the sash detached. The angle on the hook and on the head of the eye guides the eye up and over the hook so that a sash or screen may be hung easily and quickly from the inside of the building. It is necessary only to set the storm sash in its proper groove in the casing and then using the groove as a guide to push up the sash. The eyes slide over and on to the hook, while the weight of the sash clamps down the eyes into place. The point is made that when the sashes are being hung or removed they need not be held far from the building, therefore there is no danger in hanging or removing them from the inside of a window equipped with the hanger illustrated herewith. The hanger is furnished with japan finish and Stanley Sherardized. The eyes or hooks may be ordered separately either from the company at New Britain or from their New York office, 100 Lafayette Street, or from their Chicago branch, 73 East Lake Street.

Decorative Concrete

Better Looking, Better Selling Products
With Your Present Equipment

We have no machinery or materials to sell—simply the process and formulas for making high grade decorative concrete. Exact reproductions of Marble, Granite, Onyx, etc., at $\frac{1}{4}$ the cost of actual marble. Block Facings, Porch Work, Composition Flooring, Interior and Exterior Trim, Mantles, etc.

You can make Art Marble Wainscoting, Tiling and Composition Floors for a Hall, Vestibule, Bath or Fire Place almost as cheap as hard wood.

ART STONE CO., Box 500 Waynesboro, Pa.

You don't buy saws often—get the best

You use your saws daily, week in and week out. If they are fine tools they are a source of constant satisfaction and pleasure. Likewise they may be a perpetual annoyance. You owe yourself and your skill as a mechanic the best you can get. We think

DISSTON SAWS

are the best made. The majority of saw users think as we do. If you have used them you are of the same opinion. But if you haven't, make it a point to get a Disston next time. Learn for yourself why they enjoy the world's greatest demand. It's all in the quality—workmanship, material, design. Write for our Hand Saw Booklet.

Make an "Inside" Fire Impossible

Safeguard your clients against inside fires by using Ambler Asbestos Building Lumber for stairways, wainscoting, partition walls, elevator shafts, ceilings, electrical insulation. Practically anything that can be made of lumber can be made of Ambler Asbestos Building Lumber. It can be sawed to any desired shape, drilled or screwed. The natural gray color is pleasing and permanent; painting as a preservative is unnecessary, but when desired, it can be painted and grained, and takes a good finish.

Ambler Asbestos Building Lumber

is made of Portland Cement, reinforced with Asbestos Fibre, built up layer on layer and then pressed free of air holes and surface irregularities. After setting and proper aging of the cement, it forms a dense, tough structure that is virtually time, weather and fireproof.

It is completely non-combustible and will not carry or communicate fire through short circuits, electric flashes, oil explosions, etc. It withstands the direct application of the highest temperature electric arc without disintegration, is an excellent heat insulator and a fair electric insulator.

We'll be glad to send our literature, and let you read the full story of Ambler Asbestos Building Lumber. Also samples for your examination and investigation.

Traditions Die Hard!

—but the "good old things" must give way to the better things.

Lath and plaster must give way and is giving way, for the more durable, stronger, stiffer, more economical and altogether more satisfactory

Trade-mark Reg. No. 94743

This is no ordinary wall board—it is a wall board in a class by itself, the *only* wall board with a center core of kiln-dried wood slats, else we would not claim it to be *better* than lath and plaster. It does not have to be paneled, but can be made into walls and ceilings smoother than lath and plaster. Can be decorated by any method—even papering—which other wall boards cannot stand.

Are you going to stick to tradition or give your customers the more modern and more satisfactory wall lining in their buildings? *Talk to us* about some of the common false notions on the subject of wall boards, and let us make clear to you just what you're overlooking.

The Compo-Board Company

5778 Lyndale Ave. No., Minneapolis, Minn.

THERE'S CLASS to a Building Finished with Kees Corners for Drop Siding

They take the place of corner boards and form a permanent and weather proof finish. Do away completely with the openings that usually are left when corner strips are nailed over the drop siding.

Like all Kees Corners, they are made of galvanized iron, treated to take and hold paint or stain.

Your Own Eyes Will Tell You Why!

One glance at those two sturdy legs—not one, but two—will tell you why "Trouble Saver" Brackets are absolutely stable. Just note how one leg braces against the other, thus preventing all side motion. Your men will feel as secure on "Trouble Saver" Brackets as on any part of the house.

Then there is another feature you cannot notice, but you will appreciate when erecting the scaffolding—you can erect as many "Trouble Saver" Brackets in five minutes as you can wooden brackets in five hours. No bolts, no nuts, no nails—not even a screw.

But don't depend entirely on your eyes. Try a few. We will lend them to you. Write for particulars.

The Steel Scaffolding Co.
Evansville Ind.

Mecca Restaurant, Frankfort, Ky.

WHY use unsanitary, quickly soiled and unsafe wood lath and plaster ceilings in the buildings you erect when

"BERGER'S"
Classik
STEEL CEILINGS

give permanent beauty and safety at reasonable cost? These ceilings are fire-resisting and non-collapsible. Bold, massive and elaborate effects or those comparatively simple and unobtrusive may be secured from the wide variety of designs. The improved bead and button construction makes erection easy and speedy.

The building owner will appreciate the many advantages of Berger's "Classik" Steel Ceilings and you'll profit well from each installation.

Install them in your next building—they're adaptable to any interior. Write for full details and Catalog D. B.

The Trolley Track

Long use and years' experience have proven the box-shaped trolley track No. 31 and No. 35 types the most satisfactory.

This type track provides two runways on which the carrier wheels roll, thus distributing the load; protects the hangers from the weather, is bird-proof, jump-proof and trouble-proof.

Sold in 4, 6, 8 and 10-foot lengths.

The Hanger

From a mechanical standpoint, the perfect design for a door hanger is the center hung type—used only in No. 31 and No. 35 types trolley track.

The four hanger wheels roll in the two smooth runways in the track; from the exact center of the two axles, which connect the four wheels, a pendant suspends to which the aprons which hold the door are attached. Thus the load is suspended from the exact center of the hanger—any variation of the door off center of gravity does not affect the easy movement of the hangers on the track.

Why not give your clients the best when it costs no more?

"A hanger for any door that slides"

The Only Tapered Asphalt Shingle

Winthrop Tapered Asphalt Shingle

Just ask for a sample shingle. See how tough, how pliable and how durable it is. See how it is made like a wooden shingle—thick at the butt and thin at the top. See how easy to lay it is. See what a beautiful roof it will make—red, green or slate-black. Then you will understand why owners want the Winthrop when they know about it.

Winthrop Tapered Asphalt Shingles will enable you to get most of the roofs in your town. They win out with less argument than anything you ever tried to sell, for they look better than wood shingles and they have all the protection of asphalt.

Name

Town Street
State or R. F. D.

Occupation

Grimm's Galvanized Corrugated Wire Lathing

"Note the V"
(Pat. Applied for)

requires no furring on account of the V-shaped corrugations which are imbedded at intervals of seven inches.

This feature alone is worth considering but that's not all. It WILL NOT RUST as it is heavily galvanized with the finest grade of Western Spelter and is much easier to handle and will conform to irregular curves much better than any other form of metal or wood lath.

Walls or ceilings plastered on this lathing WILL NOT CRACK OR DROP OFF, owing to its great keying qualities, which we will explain if you will drop us a card asking for our booklet No. 61 and samples.

We also manufacture Greening's Patent Trussed Steel Wire Lathing, "Buffalo" Crimped Wire Concrete Reinforcing, "Buffalo" Wire Cloth of all kinds and Wire and Artistic Metal Work for all purposes. DROP US A LINE AT ONCE and ask for Catalog 8-H.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912.

Of BUILDING AGE, published monthly at New York, N. Y., for October 1, 1916.

State of New York, County of New York, ss.:

Before me, a Notary Public in and for the State and county aforesaid, personally appeared Edwin J. Rosencrans, who, having been duly sworn according to law, deposes and says that he is the Managing Editor of the BUILDING AGE, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management, etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business manager are:

Publisher, The American Architect, Inc., 50 Union Square, New York City. Editor, Henry Colwell, 50 Union Square, New York City. Managing Editor, Edwin J. Rosencrans, 50 Union Square, New York City. Business Manager, John B. Bennett, 50 Union Square, New York City.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

The American Architect, Incorporated (Owner), 50 Union Square, New York City.

George E. Sly (Stockholder), 50 Union Square, New York City.

Edwin J. Rosencrans (Stockholder), 50 Union Square, New York City.

David Williams Company (Stockholder), 239 West 39th St., New York City.

United Publishers Corporation (Stockholder), 239 West 39th St., New York City.

That the stockholders owning or holding 1 per cent or more of the total amount of stock of the United Publishers Corporation are as follows:

H. M. Sweetland, 231 West 39th St., New York, N. Y.; C. T. Root, 231 West 39th St., New York, N. Y.; C. C. Phillips, 231 W. 39th St., New York, N. Y.; W. H. Taylor, 231 West 39th St., New York, N. Y.; A. C. Pearson, 231 West 39th St., New York, N. Y.; M. Holtz, 231 West 39th St., New York, N. Y.; F. T. Root, 231 West 39th St., New York, N. Y.; W. H. Lindsay, 231 West 39th St., New York, N. Y.; Fritz J. Frank, 231 West 39th St., New York, N. Y.; M. C. Robbins, 231 West 39th St., New York, N. Y.; W. I. Ralph, 231 West 39th St., New York, N. Y.; George H. Griffiths, 231 West 39th St., New York, N. Y.; J. M. Phillips, Upper Montclair, N. J.; Estate of I. A. McKeel, Montclair, N. J.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.)

There are no bondholders, mortgagees, or other security holders.

That there are no bondholders, mortgagees, or holders of other securities of the David Williams Company.

That the bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of the total amount of bonds, mortgages, or other securities of the United Publishers Corporation are as follows:

H. M. Sweetland, 231 West 39th St., New York, N. Y.; C. T. Root, 231 West 39th St., New York, N. Y.; C. G. Phillips, 231 West 39th St., New York, N. Y.; W. H. Taylor, 231 West 39th St., New York, N. Y.; W. I. Ralph, 231 West 39th St., New York, N. Y.; F. T. Root, 231 West 39th St., New York, N. Y.; W. H. Lindsay, 231 West 39th St., New York, N. Y.; Saunders Norvell, 91 Fulton St., New York, N. Y.; Estate of I. A. McKeel, Montclair, N. J.; E. D. Whittemore, Evanston, Ill.; E. S. Root, 309 West 92d St., New York, N. Y.; J. M. Phillips, Upper Montclair, N. J.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

EDWIN J. ROSENCRANS,
Managing Editor.

Sworn to and subscribed before me this 5th day of October, 1916.

E. H. MINER, Notary Public No. 176.
(My commission expires March 30, 1918.)

ROBERDS
RIDEAL
Wall Board

**A PERFECT REPRODUCTION
OF NATURE'S BEAUTIFUL WOODS**

Experts are deceived by its natural effect. It pleases the owner and adds a source of income to the builder. Does not shrink or warp—is waterproof. Made in quartered oak, mission oak, tan or gray. Write for samples, booklets and prices.

Roberds Manufacturing Co.
101 Spencer Avenue
Marion, Ind.

Beaver Board the Ceiling

"You can't expect Beaver Board results unless this trade-mark is on the back of the board you buy."

Even though the walls are plastered the ceiling should *always* be Beaver Board.

Not only because it can't crack, chip or fall.

Not only because it will last longer.

Not only because it is easiest to apply.

But also because it's more attractive. Even those who object to paneled walls will appreciate the relief which Beaver Board paneling or beamed effects afford from the usual ceiling monotony.

Every Beaver Board job is one more job for the carpenter.

Write for booklet and samples.

SYKES
EXPANDED CUP
METAL LATH

Self-Furring

Saves 5 to 10 cts. a sq. yd.

Use Sykes Metal Lath—get the stability of its extra weight—make the saving assured by the fact that furring strips are not necessary—a saving of 5 to 10 cts. a sq. yd.

Easy to apply. Can't be applied wrong.

Sykes is superior for interior work, as well. By giving greater rigidity it saves workmen's time.

Architects approve Sykes Expanded Cup Metal Lath. U. S. Government indorses it for Post Office Work.

Write for Free Sample and Booklet—Specifications for Stucco on Metal Lath. This points the way to money saving.

27 years of experience builds every "Almetal" StoreFront

Almetal

HERE is no better way to learn your requirements than by experience—and we've had 27 years of it.

"ALMETAL" construction makes friends among Architects and Contractors because of its simplicity and safety. Any carpenter can install it, for it's handled just like wood-stops—just as safe and far more attractive. The heavy-gauge copper, the creosote-dipped cushion blocks, the ventilation, the prompt shipments and moderate prices have made for us an enviable position in building circles.

We'll gladly send a detail sheet.

What Will this House Cost?

A Knowledge of Plan Reading and Estimating Means MONEY FOR YOU

Could You

- estimate the cost of this building
- draw the plans for this building
- superintend the construction of this building
- take the contract to build this building

?

Successful men don't guess, they know! To succeed in any branch of the building business you must have a complete knowledge of plans and specifications. You must be able to estimate closely the cost of material and labor. Guessing won't do—you must know. This knowledge is what makes successful foremen, superintendents and general contractors. This knowledge means money—thousands of dollars—to any builder—to you!

Learn at Home Your spare time is enough to master these subjects by our new, easy, quick method. The same expert instructors who are so successful with hundreds of men in our Day and Evening Classes will guide you to a larger success. These instructors are among Chicago's leading Architects, Engineers, Estimators and Contractors. They prepare your instruction matter; they examine and approve your work. They are themselves in charge of real work—big work—and know exactly the training you need.

BAYONNE

Without a Rival

The best ordinary canvas, even if filled and painted in the most perfect manner, cannot reach the water, weather and wear resisting qualities of

BAYONNE

and the flimsiest canvas will now cost you as much, if not more—with paint at \$2.50 a gallon.

Bayonne is laid on the dry boards—requires no filling and only a light finishing coat.

Write for Sample Book "D" giving prices and laying instructions. See Sweet's, Page 426.

Branch House: 202-204 Market St., St. Louis

Everything for the House

Everything for the Garden

Everything for the Grounds

Special Offer—6 Issues for \$1

TO CONVINCE YOU that House & Garden is personally valuable to you, we will send you the next six numbers for only \$1—you see, you save 50c. for the annual subscription is \$3—if you fill out and mail us the coupon now. These six numbers comprise:

House Planning Number Garden Planning Number
Christmas Gift Number Spring Garden Guide
Annual Building Number Spring Building Number

If you have a garden, or are going to have a garden; if you own a house, or are going to build a house, you will find these six numbers full of positively invaluable advice and suggestion.

One trifling dollar invested in them now will save you \$100—perhaps \$1,000.

Mail the coupon now—before you forget or mislay this offer.

Study Interior Decoration with House & Garden

House & Garden will be your guide in matters of interior decoration, architecture, and the planning of your garden and grounds. Smart women everywhere are studying interior decoration so that they may express in their homes their own personality and taste.

Not only does House & Garden show at what effects the amateur interior decorator should aim, but it tells specifically how to achieve them—where, from whom, and for about how much you can actually purchase the wall papers, draperies, and furniture necessary to work out your color scheme.

House & Garden assists you to decide intelligently on:

Rugs	Antiques	Old-fashioned gardens
Pottery	Furniture	Landscape gardens
China	Architecture	Tree Planting
Fabrics	Sanitation	Motors and Garages
Curios	Formal gardens	Stable and kennels

Through House & Garden's guidance, you can secure full value for every dollar of your house allowance—no matter how large or how small—and save the magazine's subscription price many times over by avoiding house mistakes.

House mistakes are costly. Hundreds—often thousands—of dollars may depend on a single decision, and expert knowledge at the critical moment prove invaluable. May we suggest that:

\$1 Invested in House & Garden

a tiny fraction of your loss on
a single ill-chosen chair

Will Save You \$100—Perhaps \$1000

Not only will you have before you now—when you are spending hundreds of dollars in refitting your home for winter—House & Garden's great House Planning and Annual Building numbers, but you will also have the benefit of its guidance in your spring garden planning and planting and in the furnishing of your summer home.

Consider, then, that by the simple act of mailing the coupon below, and at your convenience for-

warding \$1—a tiny fraction of your money loss on a single ill-chosen chair or set of hangings—you insure expert advice on all your house planning and furnishing problems this winter and spring.

If you care to make your home smart and distinguished in its furnishing and equipment, then you will want to take advantage of our special offer of 6 issues of House & Garden for \$1—seven, if you mail the coupon now.

HOUSE & GARDEN, 445 Fourth Avenue, New York City
Send me six numbers of House & Garden, beginning with the November Number, for which I enclose \$1, here-with (OR) enter my subscription for the next six numbers beginning with November, \$1.50. Canadian \$1.25.

FREE 224-page Plan Book and Consulting Service

This is more than a bargain offer on an authoritative set of books. We are giving away, absolutely free, in connection with the new edition of the Cyclopaedia of Architecture, Carpentry and Building, a 224-page Plan Book and a year's consulting service in the American Technical Society. The plan book (Modern American Homes) contains plans and specifications for 168 different structures, designed by the leading architects. The pages are 9 1/4 x 12 3/4 inches (426 illustrations).

The year's consulting membership in the American Technical Society gives you the privilege of consulting the final authorities in regard to your problems. It is a service that regularly sells for \$12.00 and in connection with this offer on the new cyclopaedia it is given to you without charge. This corps of experts ever stand ready to solve your perplexing problems, to offer suggestions and to point out the things you should avoid.

Everything About Architecture, Carpentry and Building

This brand new set of the Cyclopaedia of Architecture, Carpentry and Building is remarkably complete. It is written in simple, easily understood language and is the most practical ever published on the practical possibilities of the modern building trade. It covers everything from cottages to skyscrapers, from plans to complete structures. It includes wood, stone, steel and reinforced concrete constructions, estimating and contracting, interior finishing and decorating, lighting and sanitation. It is the work of 40 experts and can be depended upon to give you any information you desire. It consists of ten volumes, handsomely bound in half black morocco, gold stamped and contains 4760 7 x 10-inch pages, 4000 illustrations, full-page plates, building plans, diagrams, etc.

\$0.50 a Week

This remarkable set may be paid for at the rate of \$0.50 a week—\$2.00 a month. But, first we send them for examination without a penny in advance so that you can use them for seven days. If you decide to buy them, you pay only \$24.80 in all—at the rate of \$2.00 a month.

Use Them Seven Days

Upon your request, all ten volumes will be sent prepaid to your home or office so that you may have the use of them seven days before you decide to buy. Merely tell us where to send the books. There is no red tape or quibbling. This offer is made to every one in the United States and Canada.

Send the Coupon—No Money

Just put your name and address on the coupon now—see these books—then decide whether or not you can afford to be without them. See the Plan Book, too, and use the Consulting Service if you wish. Then decide whether or not it is worth \$0.50 a week until \$24.80 has been paid. But send the coupon now. Decide after you get the books.

Partial Table of Contents

Mechanical, Freehand, Perspective and Architectural Drawing, Lettering, Pen and Ink Rendering, The Orders, Superintendence, Strength of Materials, Masonry, Reinforced Concrete, Carpentry, Steel Square, Stair-Building, Hardware, Steel Construction, Roof Trusses, Practical Problems, Estimating, Contracts, Specifications, Building Law, Sanitation, Sheet Metal Work, Electric Wiring and Lighting.

American Technical Society
Dept., R-1878, Chicago

Please send Free Plan Book, also Cyclopaedia of Architecture, Carpentry and Building, for seven days' examination. I will send \$2.00 within seven days and \$2.00 a month until I have paid \$24.80 for Cyclopaedia (Plan Book and year's Consulting Membership included free), or notify you and hold books subject to your order. Title not to pass until fully paid.

\$8,000,000.00

Represents Fire Losses Caused by Lightning in One Year in the United States Alone.

90 Per Cent. of this Loss Was in the Farming Districts.

Why?

Because many farmers, influenced by a mistaken idea of economy, use inflammable building materials. They risk their buildings, crops and live stock to save a few dollars.

The isolation of the farmer leaves him without the means to fight fire once started.

The Secretary of one Farm Mutual Insurance Company says: "Eighty-five per cent of the losses of my company during a year are caused by lightning."

Another says: "Every loss in my company during the year 1913, with one exception, was caused by lightning."

Eliminate the risk of loss of fire by lightning, by using sheet metal building products.

Milwaukee Corrugating Co., Milwaukee

BRANCH AT KANSAS CITY, MO.

"Lightning Proof"

Statistics prove that metal roofing is the only positive protection against fire by lightning.

The use of Metal Roofing and Siding and other Sheet Metal Building Materials insures not only protection from loss by fire, but its durability and long life make it even more desirable as a building material.

To be doubly insured against loss insist on getting **"MILCOR"** Products.

"MILCOR"

BARN CUPOLAS

Made Entirely of Steel

These five points tell the story about **"MILCOR"** Cupolas—

- 1—Strong corrugated weather shield.
- 2—Perfect ventilation.
- 3—Attractive stamped shingle effect.
- 4—Architecturally correct.
- 5—All-steel base—no wood used.

There Is Economy In Berger Building Material

Berger's Expanded Metal Lath

Adds strength and stability to a building. Used for Stucco Walls, Partitions, Ceilings and all kinds of work where plaster is required.

It prevents cracking; does not swell, warp or stain the plaster; prevents rats from making holes through walls; and is quickly and easily applied.

The diamond-shaped openings are small and expanded in such a manner as to insure a perfect "Clinch" of plaster.

Sheets 18 in. by 96 in. They may be easily broken up into small members for cornices, coves, etc.

Berger's Base Screed

A metal screed that is nailed in place, affording a permanent ground for the plaster above and the cement base below. It protects both plaster and cement at all times, thus eliminates patching and insures a sanitary base.

Send coupon for samples, prices and full particulars. Do it now.

Berger's Corner Beads

insure a smooth, round corner to which the plaster properly adheres. Prevent plaster from cracking or chipping at the corners, thereby eliminating patching and doing away with old-fashioned wooden mould. Standard lengths of all beads are 6, 7, 8, 9 and 10 feet.

Willis Ventilators on farm
of A. A. Poiset, Stock
Raiser, Avon, Ill.

WILLIS VENTILATORS

for Farm Buildings, Houses, Factories, Churches, etc.; are guaranteed to furnish maximum supply of fresh air. 25 years of good ventilating experience back of them. Made of the best grades of Sheet Metal—scientifically constructed—they represent the best obtainable in Ventilators.

Durable, Rust and Bird Proof. No Down Drafts

Made in several styles and all sizes,
with or without weather vanes

There is a good business to be secured installing Ventilators. Why not install the WILLIS? They give universal satisfaction.

Write for the Willis Catalog

It describes other Willis Sheet Metal Products, including Skylights, Fireproof Doors and Windows bearing the Underwriters' Label—Canopies, Metal Ceilings, etc.; in fact, everything in Sheet Metal Building Materials. A copy of this Catalog will be mailed to you upon request.

WILLIS MFG. CO., Dept. "A"
Galesburg, Ill.

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

National Sheet Metal Roofing Co., 339-345 Grand Street
JERSEY CITY, N. J.

All Buildings Settle

BUT all stuccos *do not crack*. You remember, of course, what happened to that *cement stucco* job three years ago. It sure did crack, didn't it? And what the owner had to say to you would fill a book. Raised Cain, didn't he?

There is one stucco that you can recommend without risk to your reputation—one, and only one, which you can use with the absolute assurance that the job is going to look as well five years from now as it does the day you complete it. This stucco is rain proof, stain proof, and so elastic that it may be deflected one and a half inches in seven feet without cracking. It will meet any condition of normal settling. That stucco is

KELLASTONE
IMPERISHABLE STUCCO

You can use it now and all winter, without risk of damage in the coldest weather. It's warmest in winter—coolest in summer, and neither winter frost nor summer sun can cause it to expand or contract. It bonds perfectly to wood, lath, brick or stone.

Used by the U. S. Government, by State Institutions, Railroads and large corporations everywhere; it's best, too, for homes of every size and cost. It solves the stucco problem permanently. Any finish which can be obtained with other stuccos may be produced with Kellastone.

We ask you to do just one thing—give us the opportunity to place before you the actual facts about this superior stucco. That's all.

KELLASTONE COMPOSITION FLOORING fulfills the average flooring requirements far better than any other flooring. It has remarkable resistance to abrasion, deadens noise, has no seams or joints, never cracks or shrinks. Lasts indefinitely.

Write today for illustrated facts.

The National Kellastone Co.
506 Association Bldg. Chicago, Ill.

High Grade Finish

When you have work requiring high finish such as built in sideboards and bookcases, window seats and such jobs, remember that you can work rapidly and well with a Starrett scraper. Eight sharp cutting edges reduce frequency of sharpening. Removable grip protects hands. Universal joint in the handle permits working in cramped corners or tight places.

Starrett Tools

are all well made and serviceable. They will increase the efficiency of every workman. The line for carpenters and wood workers includes steel tapes, rules, squares, levels, builders' combination tool, compasses, trammels, steel marking gage, scrapers, etc.

Send for free Catalog No. 21-P describing the full line.

The L.S. Starrett Co.

The World's Greatest Tool Makers

Are they worth saving?

Schooley's Circular Barn, Tillie, Adams County, Pa. Covered with Ambler Asbestos Shingles "Century Brand." A practical idea on livestock housing, labor-saving, ventilation and lighting — and SAFETY.

TODAY the builder who is in the farm field to win trade and reputation is solving this question by roofing — and often siding — with Ambler Asbestos Shingles "Century Brand." Because they are (1) absolutely fireproof; (2) weatherproof against freezes, scorching suns, rains, snows or ripping winds; (3) are beautiful to the eye; (4) will re-

main beautiful and efficient indefinitely without repairing, painting or any attention whatever; (5) are the acme of real roofing economy.

AMBLER Asbestos Shingles

The Roof That Is as Permanent as the Foundation

are made of Portland cement and Asbestos fibre, the Asbestos fibre reinforcing the cement as steel rods do a wall. They grow stronger and tougher when exposed to the elements and practically last forever. They are made in three colors: Newport Gray, Indian Red and Blue Black. These colors are natural and never fade or lose their freshness. Ambler Asbestos Shingles are light in weight and can easily be carried by any good rafters; are ideal for renewal work.

Write for our booklet—"A Spark May Cost a Farm"—showing some of the costliest farm buildings in the country, covered with Ambler Asbestos Shingles "Century Brand." Get the full story; let us quote figures and send you samples.

Bay State "Agatex"

Makes Better Cement Floors

Rough cement floors have a tendency to be damp, to dust and to wear away unevenly. Dampness and dust are detrimental to health and comfort and to the room's contents. These drawbacks are easily overcome by using Bay State "Agatex."

This is a cement floor filler which is wearproof, dustproof, oilproof and waterproof. Easy to apply and economical.

One gallon will coat 400 to 450 square feet on floors of ordinary texture and condition. Bay State "Agatex" is extremely long wearing.

Write for circular 19 giving detailed information about Bay State Agatex.

WADSWORTH, HOWLAND & CO., Inc.
Boston, Mass.
New York Office: Architects' Building

"Trussit"

For Solid Partitions

Trussit reinforcement is expanded in both directions alike and woven back and forth through the concrete slab, giving uniform strength and ample stiffness and rigidity to make studding unnecessary.

This rigidity and strength permit the erection of Trussit partitions but two inches in thickness that are space-saving and wonderfully rigid, and of curtain walls the equal of brick or poured concrete at a fraction of their cost.

The Fireproofing Handbook illustrates and describes the many uses of Trussit. Write for a copy.

"I can recommend it"

"I was a Builder
3000 years ago
and My efforts
are still standing"

—and the same principles in use when the pyramids were built, used in building construction ever since, and *today* acknowledged the most efficient, are combined in that modern, dependable background for stucco, cement or plaster finished houses

Bishopric Board will not corrode—it cannot break away or sag. It contains nothing but creosoted lath, asphalt-mastic, and heavy fibre board, that will outlast any materials known, that is proof against moisture, vermin, heat and cold, and that holds the stucco in its dovetailed grip so it can't crack, loosen or let go.

Bishopric Board costs less than other backgrounds and saves at least 25% in material and labor.

Our book "Built on the Wisdom of Ages"

gives facts and figures to prove our claims. It also illustrates homes, apartments, factories and public buildings constructed with Bishopric Board, and gives letters from architects, builders and users, also some interesting results of scientific tests.

Write today for samples and this book—all free.

"Famous"

For the Large or Small Contractor In the Shop or on the Job

The Famous Universal Woodworker is a machine whose multiplicity of utility makes it an asset potent in its advantages.

So designed that almost any desired equipment may be combined in one machine, and thirty or more different kinds of work can be done successfully by one equipment.

The impossibility of this accomplishment on any other machine is well known.

The Sidney Tool Co., Sidney, Ohio

A NEW motor car provided by Santa may provide you with the opportunity to build a garage.

No feature of your garages deserves more careful consideration than the doors.

Stanley Garage Hardware

insures doors that work easily and conveniently

SLIDING doors do not, as a rule, prove satisfactory. They have an annoying tendency to stick and get out of order, they cannot be made weather-tight, and the tracks frequently become clogged with snow or dirt. These troubles are avoided if you swing your doors on ball-

bearing Stanley Garage Hinges, and secure them with Stanley Garage Latches and Bolts. The Stanley Garage Door Holder, pictured above, makes it impossible for your doors to slam against the car as it enters or leaves the garage.

Write today for the Stanley Garage Hardware Catalog E12. It contains information of great value to builders.

Any of the better Builders' Hardware stores can show you Stanley Garage Hardware.

Quality vs. Price

It costs no more to advertise and sell a good article than it does an inferior one. Consequently, when you buy a good article you pay only as much more for it as the difference in material and manufacturing cost necessitates.

Anyone who has ever used a Triple "A" will tell you that it is easily the best floor surfacing machine on the market. With this machine it is comparatively easy for a carpenter to scrape from 200 to 400 square feet of floor space per hour and do good work.

Those who are not familiar with the wonderful speed and power supplying features of the Triple "A" Spring Motor will say "Impossible."

You can never believe what a big

help the spring motor really is on a floor surfacing machine until you have actually tried it for yourself.

In comparison with other hand power machines, the Triple "A" Spring Driven will surface three (3) times the amount of floor space without a bit more effort

on the part of the operator.

That is the big difference, compared to which the difference in price is a mere trifle.

In addition to its remarkable work performing capacity, the Triple "A" is also famous for the superior quality of the work it does, its ease of operation and its many convenient adjustments.

Send for booklet fully describing this highly efficient floor surfacing machine.

To prove our claims we will gladly send you a machine on FREE TRIAL

Triple "A" Machine Company, 4101 Ravenswood Ave.

S. CHENEY & SON, Dept. B, Manlius, New York

The Shingles of our Grandfathers

Were made of Clear Heart Swamp Cypress—rived and shaved by negro slaves—entirely by hand.

Today—we are making our "HAMMER" Brand Split and Shaved Cypress Shingles in precisely the same manner as in olden times.

Modern methods of grading and inspecting bring this old fashioned product up to the highest present standards, and insure the home-builder of a uniformly perfect shingle, as far as quality goes. But it still leaves the slight variations which give character and charm to this truly Colonial product.

Made in two sizes— $\frac{1}{2}$ " x 6" x 20" and $\frac{3}{4}$ " x 7" x 24".

The HAMMER LUMBER CO., Franklin Bank Bldg.
Philadelphia

Stop Making "Borderwork"

around your baseboards—which results when you use a narrow edge roll attachment, as its work is uneven and looks different from the rest of the room when finished. Get the same uniform work right up to baseboards that you do throughout the room by using

The Improved Type Automatic Ball-Bearing Electric Floor-Surfacing Machine

The sanding roller is mounted so one end extends just beyond the side of the machine—easily adjustable to either side so that the wall all around the room can be reached and the **Little Automatic Electric Surfacing Machine** (shown below) is a wonder for removing old varnish from desk tops, tables, counters, etc., as well as for dressing up new work.

Van Guilder Hollow Wall Concrete Construction

"Built Like a Thermos Bottle"

Van Guilder hollow wall machines build a two-piece hollow wall, using wet mix concrete, molding a 9-inch course $4\frac{1}{4}$ feet long at each operation, and being immediately released and moved forward on the work.

These machines are used in all classes of building construction from bungalows and garages to factories and apartment houses.

Van Guilder buildings are warm in winter, cool in summer and always dry. Van Guilder construction competes in price with the cost of frame.

Write for booklet describing Van Guilder construction in detail.

SIMPLICITY

EVERY part of Almetal Store Front construction is simple in design and simple to install. Every part is built to perform its function in the most natural way.

THE sash, for instance, is so built that the glass is held without strain. Its principle has been used since glass became a part of building. Builders have always favored this simple construction. The possibility of glass breakage is reduced to the minimum.

THE two-piece corner bars also follow that same simple method of safely holding to joining plates of glass.

STURDINESS, simplicity, attractiveness and safety are built into every part of Almetal construction.

WHY not have Almetal details on file? You'll find them easy to use on your next Store Front job.

Steel "Stitches"

Every Few Inches

Columns which have staves simply glued together will surely open up. Columns which have any kind of a lock-joint are liable to open up. Columns which are glued under hydraulic pressure, where the staves are locked with a double V joint and sewed with cold rolled steel staples every few inches of their entire length *cannot* open up. And this is the way "Steel-Sewed" Columns are always made. Catalog explains the construction and shows many beautiful illustrations. Write for it.

AMERICAN COLUMN CO., Battle Creek, Mich.

"The Standard" Low Charging Concrete Mixer

Will enable you to rush your concrete work before cold weather on account of the low charging platform which is only 24" high. It avoids the necessity of using troublesome and heavy side loaders or high charging hoppers.

For concreting in cold weather "The Standard" can be placed inside the building and moved along the work and from floor to floor. Its light weight and sturdy construction make this possible.

Low Charging is saving thousands of contractors and builders throughout the country one-third on their concrete work. Are you one of them? Our complete mixer Catalog No. 48-12 will be mailed for the asking.

A Popular Lansing For Building Contractors

Lansing No. 5 "Half-Sack" Batch Mixer

This Lansing No. 5 has the distinction of being the youngest member of the Lansing family. It is also the smallest. Like all other Lansing mixers it is deservedly popular. Just plain "making good" has put it in the front ranks.

For walks, curbing, small foundations, and the average country job, it is the ideal outfit.

If you use more than thirty or forty cubic yards of concrete a day this isn't your size.

Costs little to run, little to buy, and effects a big saving.

Equipped as ordered with loader, tank, silo hoist, batch measuring hopper, etc.

A special circular describes this mixer in detail. Ask for it and catalog No. 21 of larger sizes.

Change in Prices

It is necessary to make an adjustment in the prices of Cortright Metal Shingles. As everyone in the trade knows, this change has been brought about by conditions in the metal market. It is a matter of maintaining the quality of

Cortright Metal Shingles

at a slight advance, or producing at a loss.

The margin of profit has never been large, and the quality has always been a matter of pride with us. Cutting this quality is not to be considered. Even at a slight advance, we feel sure that our customers will gladly co-operate with us in maintaining our well known standard of excellence. Therefore, beginning immediately this price adjustment will become effective.

The Question of Bungalows

The bungalow question finds a simple and practical solution in the inexpensive books listed below:

THE books described have been selected from all those published on the subject because of their artistic arrangement and the fact that our customers have found them satisfactory. The types of bungalows illustrated are suited to all climates and all purses; the average cost of erecting the building shown in each book being given in the description under each title. Working plans and specifications for any design in a majority of these books may be bought at nominal prices.

THE BUNGALOW BOOK. The best book on this subject. Contains photographs and floor plans for 117 artistic structures with interior and exterior details. The bungalows shown have been erected at costs ranging from \$800 to \$4,000. 159 pages, 7x10 inches, 261 figures. Cloth, \$1.00.

BUNGALOWCRAFT. 87 floor plans of bungalows for any climate that have been built at prices ranging from \$1,000 to \$4,500. 128 pages, 7 1-2 x 11 inches. 248 figures. Heavy paper, \$1.00.

MODERN HOMES OF CALIFORNIA. 77 designs with floor plans and interiors of bungalows that have been built at costs ranging from \$1,500 to \$4,500. 95 pages, 7x10 inches. 205 figures. Paper, \$0.50.

WILSON'S CALIFORNIA BUNGALOWS. One of the most interesting books on bungalow planning. It contains 75 designs of artistic homes built at costs ranging from \$700 to \$3000. A feature of this volume is a splendid collection of interiors and details of living room, kitchen, bathroom, buffets, mantels, fireplaces, windows, doors and builders' hardware. There are 61 of these and a complete set of plans of a bungalow reduced in size to show exactly what you get when you order the working plans of any bungalow shown in the book. 128 pages, 7x10 inches, 235 figures. Heavy paper, \$0.50.

PRACTICAL BUNGALOWS FOR TOWN AND COUNTRY. Over 200 bungalows and cottages costing from \$500 to \$3800 are shown in this volume. 420 pages, 5x8 inches, 400 figures. Cloth, \$1.00.

BUNGALOWS, CAMPS, AND MOUNTAIN HOUSES. Presents the ideas and plans of 32 different architects and a special article on the planning of a bungalow with detail sketches showing how to plan conveniences in the house, and a plate showing 22 different schemes for arranging floor plans. 146 pages, 7x10 inches, 200 figures. Cloth, \$2.00.

PRACTICAL BUNGALOWS. An attractive volume containing 77 plans of one and two story bungalows costing from \$2400 to \$9000. 96 pages, 7x10 inches. 201 figures. Paper, \$0.50.

INEXPENSIVE BUNGALOWS. An artistic collection of 85 low priced bungalows erected in various sections of the United States and Canada at costs ranging from \$1500 to \$2400. 96 pages, 7x10 inches, 196 figures. Heavy paper, \$0.50.

Keeps Down Investment —Brings Up Profit

Builders of investment property desire the lowest possible cost because cost determines the profit on the investment.

Yet, at the same time, they must not sacrifice either quality or appearance. Give them what they want! Recommend the one wood that best serves their purpose—

North Carolina Pine

"The Wood Universal"

No wood at the price can equal it, whether used for interior or exterior work.

It possesses a rare beauty of grain; is splendidly responsive to paints, varnishes, wax, stains or enamels; is strong and durable and easy to work. And it is exceptionally low in cost.

Send for Free Reference Book

We have prepared a most instructive reference book on North Carolina Pine. It is not merely a compendium on North Carolina Pine but a most profitable help to every contractor and builder. Ask for Book B.

Woods and Their Uses

ALL woods have certain uses for which they are especially adapted by reason of the peculiar qualities and characteristics which nature has given them; and on their proper selection for these uses, hinges the whole problem of economy in wood construction.

Three centuries of experience in this country have demonstrated that no other wood lasts so long or gives such satisfactory service as

WHITE PINE

for outside finish lumber—siding and corner boards; window sash, frames and casings; outside doors, door frames and casings; outside blinds; all exposed porch and balcony lumber; cornice boards, brackets, ornaments and mouldings; and other outside requirements, *not* including shingles.

If the lumber dealers supplying your clients are at any time unable to furnish it, we should appreciate the opportunity of being helpful to you in securing it.

— A Free Magazine for Contractors

We are now publishing a bi-monthly architectural magazine, every issue of which is full of valuable and helpful information for contractors and builders. If you would like this magazine, write us and we will be pleased to place your name on our mailing list.

Stained with Cabot's Stucco Stains
H. A. Perkins, Architect, Boston

Dingy Stucco Houses Made Fresh, Bright and Cheerful

If you want to brighten up stucco houses that have become dingy and dirty from smoke and dust, and make them look like clean and cheerful places to live in, you can do it at small cost with

Cabot's Stucco Stains (Waterproof)

A stucco house brightened up with these stains looks 100 per cent better, and the stucco is protected from dampness, freezing and crumbling, because the Stains are rainproof. They cost far less than the heavy paints or coatings, and they can be applied twice as quickly and easily. They don't cover the stucco with a painty coating, but preserve the natural texture in nice, soft tints that are artistic and pleasing.

Send for Color-card and Catalog—Free.

More Money for You

Mr. Contractor, build up a profitable business this Winter laying and finishing our Fine Hardwood Flooring.

You will find many houses in your town which need new floors, and the time to put them in is when the cold weather prevents outside work.

No special experience is required. Our books give you full information about the flooring and how to lay it. Our Service Department helps you get the orders.

Why not learn more about this money-making side-line now? Write today for our Special Agency Plan.

The Interior Hardwood Co.
1332 Beecher Street Indianapolis, Indiana

Section of Outside Wall of House, Showing Wool Between Studding.

Mineral Wool for Building

Mineral Wool has superseded all other materials used for similar building purposes because it does "a great work at little expense." A house lined with Mineral Wool has an indestructible, fire-proof and vermin-proof guard; it protects the entire household. In the winter time it keeps the cold air out, facilitating proper heating and economy in fuel. In the summer it keeps the heat out.

This material, being of fibrous, inelastic composition, acts as a deadener and muffles all sound. It is considered the best insulator material on the market, making it a perfect refrigerating machine.

Mineral Wool makes life-long friends of all its users. If you are skeptical as to its power, let us demonstrate. We can prove all claims. Write us to-day.

U. S. Mineral Wool Co.

280 Madison Ave., New York
(Cor. 40th St.)

Section of Sound-Proof and Fire-Proof Partition. Can be used for outside walls also.

BUILDING AGE

NEW YORK, DECEMBER, 1916

COTTAGE OF MR. L. D. HUDSON AT PELHAMWOOD, NEW YORK—ARCHITECT, W. S. MOORE

FRAME COTTAGE IN A NEW YORK SUBURB

A DESIGN OF THE SEMI-BUNGALOW STYLE
ADAPTED TO THE CLIMATE OF NEW YORK STATE

THE interest manifested in attractive country houses of moderate size and cost is the direct result of a growing demand for dwellings of compact and convenient plan. It is also desirable that the architectural features be such as to command attention by reason of their excellence of balance and design. Houses which typify this modern tendency are therefore of great interest to the builder of small homes, for a study of their predominating features is of value to him in his business as contractor.

The design here illustrated and described was the result of a desire on the part of the owner to have a house patterned after the California style of bungalow but adapted to the climate prevailing in New York State. As many of the bedrooms as possible were to be located on the first floor, so that the climbing of stairs might be reduced to a min-

imum. These first floor sleeping apartments were to be separated from the general living quarters as much as possible, and the way in which the problem was solved may be gathered from a glance at the floor plans. The two bedrooms and bath are well apart from the living room and kitchen, while the living room, dining room and enclosed porch open into each other in a manner which permits of the free circulation of air typical of the California bungalow, and yet permits of each being shut off from the others should the rigours of winter require. The pergola, placed to receive the warm rays of the sun, forms a pleasant summer addition to the dining room. Two bedrooms and a bath on the second floor complete the layout.

The footings are composed of flat stones extending 4 inches on each side of the foundation wall and stone is also used for the footings under piers.

Front Elevation Showing Some of the External Features of Architectural Treatment—Scale $\frac{3}{32}$ In. to the Foot

Elevation in Dining Room Showing Paneling, Plate Rail, etc.—Scale $\frac{1}{4}$ In. to the Foot

Second Floor Plan—Scale $\frac{1}{16}$ In. to the Foot

Main Floor Plan—Scale $\frac{1}{16}$ In. to the Foot

Section and Elevations of Kitchen Cupboards—Scale $\frac{1}{4}$ In. to the Foot

PLANS, ELEVATIONS AND MISCELLANEOUS CONSTRUCTIVE DETAILS

The footing under the rear porch steps is of cement.

The foundation walls and piers are of random rubble, the intersections between the stones being filled with spalls and cement mortar in the proportion of one part Portland cement to three parts sand with no more lime than one-third the amount of cement. The wall joints are pointed with waterproof cement below grade, and above grade with tinted cement mortar.

The cellar floor is of a 1:2:5 concrete mixture, the stone being of a size to pass through a 2-in. ring. Over this is laid a top dressing 1 in. thick, composed of one part cement and two parts sand.

The timber used in the framing is of spruce, the sizes of the various members being as follows: sill 4 x 6 in., first floor joists 2 x 10 in. let into the sill, and second floor joists 2 x 8 in. all spaced 16 in. on center and cross-bridged with 1 x 3 in. bridging

paper, over which are placed 20 in. white cedar shingles exposed 8 in. to the weather. These shingles were given three coats of white paint.

All exterior trim is of cypress, the painting of which was three coat work.

The rear porch floor is of 1 $\frac{1}{8}$ by 2 $\frac{1}{2}$ -in. Oregon fir laid with a slight pitch. The ceiling is of $\frac{7}{8}$ x 4-in. double beaded tongued and grooved North Carolina pine finished at the wall of the building with a $\frac{7}{8}$ x 6-in. frieze board and a $\frac{7}{8}$ -in. cove molding against the ceiling.

The treads of the rear and front porch steps are 1 $\frac{1}{8}$ in. thick and the risers are $\frac{7}{8}$ in. thick. The front steps are built between cheeks finished at the top with $\frac{7}{8}$ x 8-in. fascia and cove molding. The porch columns are square and have a cap and base.

A lattice is placed on each side of the front windows to the left of the bay and under

REAR VIEW OF RESIDENCE OF MR. L. D. HUDSON, SHOWING ENTRANCE TO GARAGE

spaced not more than 6 ft. on centers. The rafters are 2 x 6 in. spaced 24 in. on centers, and studs 2 x 4 in. spaced 16 in. on centers. The floor joists are doubled under all parallel partitions and headers and trimmers are also doubled. The beams used for the ceiling of the second floor are 2 x 6 in. also spaced 16 in. on centers.

The main roof and dormers are covered with $\frac{7}{8}$ x 2-in. spruce shingle lath spaced 5 in. on centers. The sheathing boards for the side walls are $\frac{7}{8}$ x 9-in. tongued and grooved yellow pine. The main and dormer roofs are covered with 18-in. cedar shingles exposed 5 in. to the weather on the main roofs and 4 in. on the dormer roofs, these being given a brush coat of Cabot's shingle stain. Shingles are used for the ridge of the main roof.

The sheathing boards of the main and dormer walls are covered with a layer of Neponset building

each of these front windows is a flower box.

Windows are of both the double hung and casement types, the latter being hinged to swing inward. The frames are cypress and the sash white pine.

The front entrance door is of oak 1 $\frac{3}{4}$ in. thick and has twelve panes of bevel plate glass. The interior doors are 1 $\frac{3}{8}$ in. thick of Colonial three-panel type, except in the living and dining rooms, where French doors are provided.

The doors and interior trim are of oak and were given one coat of stain, one coat of shellac and one coat of deadlac. Walls and ceilings are plastered with three-coat work.

Entrance to the house is through an enclosed porch which opens directly into the living room. The feature of the latter is the fireplace, which is constructed of selected field stone, the joints being pointed with tinted cement mortar. The hearth is

composed of 6 x 6-in. red tile. The flue lining is terra cotta and the flue is 13 x 13 in. An ash pit, provided with iron frame, door and drop, is so placed as to receive the ashes. The fireplace is provided with arch bar and Covert damper. There is also an oak mantel 4½ in. thick. On the opposite side of the fireplace is a large bay window containing two seats divided by a radiator. On each side of this bay is an oak bookcase.

The floors of the living room, enclosed porch and dining room are double and consist of a sub-floor

7-in. material. There is a plate shelf 6 ft. above the floor and it is paneled underneath with ⅞ x 3-in. strips placed about 18 in. apart and there is a ¾-in. ogee mold around the panels.

As can be seen from an examination of the first floor plan and fireplace detail, the stairs open from the small hall which serves to connect the various parts of the house and rise to a landing back of the fireplace, from whence they turn and become visible at the left of the fireplace. The stairs are of oak, the treads and landing being 1½ in. thick and the

of ⅞ x 9-in. tongued and grooved yellow pine over which was placed a layer of deadening felt which in turn received the finished floor of ⅞ x 2½-in. oak. The completed floor has a border six boards wide and a finish of one coat of paste filler and two coats of Supremis.

The dining room can be reached either from the living room or from the enclosed porch and opens upon a pergola. The feature of this room is the beam ceiling, which is made of 3½ x 7-in. and 4 x

risers ⅞ in. thick. The newels are 5 in. square, the rail is 2½ x 3 in., and the balusters are 1½ in. square, three to a tread.

The kitchen can be entered either directly from the dining room or from the stair hall. It contains a gas range which has an oven, warming shelf, hood, vent, etc. The wall back of the range consists of 6 x 6 in. white glazed tile with cove bottom, rounded sides and molded cap, all laid up in white cement. It is 6 ft. high and 4 ft. wide. Metal lath

VIEW IN LIVING ROOM, SHOWING MASONRY FIREPLACE AND CHIMNEY BREAST AT THE RIGHT WITH WINDOW SEAT AT THE LEFT

The trim and doors were given one coat of shellac and one coat of varnish.

The floor in the kitchen and the other parts of the house, excepting the baths, are double, like the oak floors just described, but the finish floor is of $\frac{7}{8}$ x $2\frac{1}{2}$ in. comb grained tongued and grooved Alabama pine, to which was applied one coat of filler and one coat of Supremis.

There are two bathrooms, the floors being of 1 in. white hexagonal tile laid up in white cement. Metal

ror in the door. The bathroom fixtures are "standard" porcelain enamel.

One of the convenient features of the house is the garage built under the kitchen. This is rendered easily possible because of the location of the dwelling upon a slope. The floor is of 3 in. of concrete of a 1:2:5 mixture. The ceiling consists of a reinforced concrete slab 3 in. thick, a 1:2:4 mixture being used, the stone being of a size to pass through a $\frac{1}{2}$ -in. ring. The reinforcement consists

of No. 26 gage "Corr" Mesh laid ribside up, the outer ribs being interlocked, pinched together and the ends lapped 2 in. These ends rest on 6 in. I-beams. Over the top of the slab were placed 2-in. wooden sleepers spaced 16 in. on centers to receive the floor above, the space between the sleepers being filled with cinder concrete. The underside of the slab received a ½-in. plaster coat composed of 5 parts Portland cement, 12 parts sand, 1 part hydrated lime, and long cattle hair. There is an iron sink provided with cold water supply and a faucet with a hose bibb.

The cellar contains a set of two part Alberine stone wash trays supported on iron legs and pro-

SULPHATE OF ZINC FOR WALLS

The sulphate of zinc treatment for concrete walls afterward to be painted has been adopted for the interior wall finish of the permanent hospital building at Panama Canal. The report of George M. Wells, resident engineer of the Building Division, describes these buildings and their interior wall finish as follows:

"A great deal of study was given to the design of these buildings in an effort to decide upon that form of composite construction that would make for economy and yet meet all the rigid requirements demanded by the health department as regards

DINING ROOM IN RESIDENCE OF MR. L. D. HUDSON AT PELHAMWOOD, NEW YORK

vided with hot and cold water fixtures and galvanized iron covers.

The building is warmed by means of vapor heat, the boiler being made by the Spencer Heater Co. It is covered with plastic asbestos cement applied in 2 coats to a total thickness of 1½ in., the outer coat being troweled to a smooth even finish.

The house is wired for electric lighting and call bells in accordance with the rules and regulations of the Board of Fire Underwriters.

The house here described is located in Pelhamwood, one of the many attractive suburbs of New York City, and was built for L. D. Hudson in accordance with plans and specifications prepared by Architect W. S. Moore, 30 East 42nd Street, New York City.

The building contractor was Makolm Johnson, 12 Hillcrest Avenue, New Rochelle, New York.

character of interior and exterior finish. It was finally decided to make the veranda and main-building walls of poured reinforced concrete, while the floors with a clear span from wall to wall across the building were to be constructed of reinforced concrete overlaid with terrazzo mosaic tile or some composition flooring for finish. Intermediate walls 6 in. or over in thickness are also to be built of reinforced concrete. Walls less than 6 in. thick are to be laid up of hollow cement blocks plastered with two-coat cement and sand stucco troweled to a smooth dead surface. The concrete walls are to be rubbed and filled to a similar finish.

"The health department demanded that the walls should be both smooth and of sufficient hardness to withstand chipping at corners, cracking or denting, and further that the treatment of the wall finish should be such that the wall could be washed with

antiseptic solutions if necessary, without in any way injuring the finish.

"It is proposed to meet these requirements with the cement walls as described, treated with chemical and painted with special paints as follows: The walls will be first given two coats of a wash of sulphate of zinc, mixed with equal parts by weight of zinc and water. The effect of this wash is to neutralize or destroy the alkalinity of the hydrated lime which comes to the surface of the concrete wall as calcium hydroxide and changes the latter into a mixture of calcium sulphate and zinc oxide. This gives a surface that has no leaching effect on linseed oil. To coats of flat-finish, oil-mixed paint of any color desired will then be applied. On this will be placed as a final finish a third coat of enamel washable wall paint.

"It can be shown that a concrete wall treated in this manner will cost far less per square than the usual three-coat, hard-finish white plaster, sized and tinted to the color desired. The difference in cost between the two methods is estimated to be approximately \$12 per 100 sq. ft. in favor of the painted wall with the additional advantage gained of a harder and more durable surface."

A SAFE WAY TO REMOVE SPLINTERS

A simple and safe surgical appliance which is worth trying, if occasion calls for something along that line, is described in a recent issue of *Woodworker*. The writer says that one of the most annoying minor accidents to which every woodworker is subjected at times is to have a sliver of wood stuck in his hand, and its removal is painful if not properly performed. If the splinter is soft wood, it cannot be removed very easily with a needle or other sharp instrument.

A very easy and effective way of removing a splinter without pain or inconvenience is to take a wide-mouthed bottle—such as a milk bottle—filled nearly full of water as hot as the glass will stand. Place the injured part over the mouth of the bottle, pressing down slightly, thus preventing any steam from escaping. This will cause the flesh to be drawn down, and in a minute or so the steam will extract the splinter, at the same time preventing the inflammation which usually follows an injury of this kind.

SOMETHING ABOUT DOUGLAS FIR

Some very interesting particulars concerning Douglas fir, which is also known as Red Fir, Yellow Fir, Oregon Fir, Columbia Pine and Douglas Spruce are presented in a pamphlet lately issued by the Government of British Columbia. It states that this wood is the most important timber tree on the North American Continent or in the world. No other one species exists in such great individual sizes, such excellence of quality and such vastness of quantity over so wide a range. No other one species is so well adapted for such a variety of uses. It is the world's "All Utility" wood.

The tree is found from Northern British Colum-

bia to Mexico, covering a range of over one million square miles, and reaches its best development on the coast of Southern British Columbia. The total quantity of Douglas Fir timber is estimated to be greater than that of all the hardwood timber in North America. With the single exception of the Sequoias of California, it is the world's largest timber tree. The average height is 150 ft. to 255 ft., with a diameter of 3 ft. to 6 ft. Exceptional trees reach over 300 ft. in height and 15 ft. in diameter.

There are only two related species, one in Western America and one in Asia. Both are small, scrubby, and commercially non-important. Douglas Fir timber is produced only in Western North America, and the best of it comes from the Pacific Coast. The wood of Douglas Fir is comparatively light, but very strong; it is the strongest wood in the world for its weight that is obtainable in commercial sizes and quantities. It is moderately hard, but easy to work, straight grained, tough, resilient and durable. It varies in texture and color from a fairly soft, fine-grained straw yellow in narrow-ringed, slow-growth trees, to a harder, coarse-grained reddish brown in fast-growing timber. It takes stain well in any shade or color. It holds nails firmly, is practically impervious to water, and is durable. When sawed tangentially (slash grain) the grain of the wood is shown in a most beautiful figuring, which makes it very attractive and widely used for interior finish of every description.

Douglas Fir is the ideal building and structural timber, because it combines the requisites of great strength, light weight, ease of handling and working, durability, beauty, and cheapness more than any other commercial timber; moreover, on account of the great size of the trees, the timber can be furnished in extraordinarily large dimensions. The wood of Douglas Fir is equally as strong and is much lighter than that of its nearest commercial competitor—Long-leaf Pine, also known as Pitch or Southern Pine. For bridge and mining timber, heavy frame, and strong planking for ship scows, dredges, railway cars, elevators, stave deals, and shores in shipbuilding yards; piles for wharves; spars, etc., it is unsurpassed.

A NEW USE FOR CEMENT

An unique contraband scheme has been uncovered in Malaga, Spain, according to the *St. Louis Post Dispatch*, as will be noted from the following cable to it from Paris:

"A Madrid dispatch to the *Petit Journal* says that 300 blocks of stucco which were shipped from Zurich to a merchant at Malaga, Spain, by way of Genoa, have been found to contain rifles and ammunition. The blocks lay for six weeks on the wharf at Malaga, no one appearing to claim them. Then one of the blocks was broken open and it was discovered that the interior was filled with rifles.

"The authorities thereupon examined the other blocks and found a total of 4000 rifles and 400,000 cartridges."

SOME ASPECTS OF MODERN SHINGLING*

METHOD OF SIDE WALL SHINGLING — VARIOUS DESIGNS OF ORNAMENTAL WORK AND HOW PRODUCED

BY EDWARD H. CRUSSELL

SHINGLES on side walls are usually laid with a greater exposure to the weather than roof shingles, 5 in. to 6 in. being the average, though the width of the courses is often varied for ornamental purposes—a matter which will be considered presently.

Side wall shingling can be done by the gage and hatchet method, but guide lines should be used more frequently than on roof work, especially for the first 6 or 7 ft., or until the work gets above the line of observation. Wall shingling cannot be done quite so rapidly as roof work, chiefly because the

In the best work it is considered proper to arrange the courses of shingles so that they come even with the tops and bottoms of the windows and with the heads of the doors. The windows on modern dwellings, however, often dodge up and down to such an extent and are of so many different sizes that it is sometimes difficult to get the spacing just right to catch all of them; and the writer knows of builders who side-step all this trouble, by disregarding the openings entirely and running an unvarying width of course from the sill to the plate. Many mechanics will condemn this

Fig. 47—Shingling on Side Walls

Fig. 48—Shingling a Corner

shingles cannot be placed so conveniently. Many different schemes have been tried for the elimination of the continued stooping after shingles, but the best method is to let the bundle lay flat on the ground or scaffold after breaking it open, and pick up the singles with the hatchet, the front corner of which is ground sharp and thin for that purpose.

The shingles are gaged from the course below in the same manner as for roof shingling, excepting that for the gaging the hatchet is held back-handed as in Fig. 47. Holding the shingle with the hatchet, and the method of nailing are exactly the same as explained for roof shingling.

method, but the "man in the street" never seems to notice the difference.

Where it is required to space the courses for the openings, the easiest way is to set out the correct spacing on a rod and use it for testing the different wall spaces. With the rod the necessary calculation can easily be made; stand it beside the opening and note where the regular spacing will bring you; suppose the line shows 2 in. above the window head, then shorten each of eight courses below it one-fourth of an inch. If you think one-fourth of an inch too much variation, then shorten sixteen courses one-eighth of an inch. If the line shows below the window head less than half the width of a course, increase the width of the courses.

*Copyrighted 1916 by Edward H. Crussell.

On the corners the joints should be broken, as already explained in the chapter on hips, and it makes a neater finish to have the corner shingles regular in size—say 5 in. on one side and 3 in. on

50. Fig. 50 is a "close-up" view of the corner of the house pictured in Fig. 49 and shows an alternate wide and narrow course. Other arrangements, such as one wide and two narrow, are often employed.

Fig. 49—Shingling with Courses of Different Widths

Fig. 50—A "Close-Up" View of Fig. 49

Fig. 51—A Good Example, Showing Appearance of Shingling Around Curved Openings

the other, alternating the order for each course, as shown in Fig. 48.

Of late years some attempt has been made to work ornamental features into the wall shingling, the most common form of which is a variation in the width of the courses, as shown in Figs. 49 and

A rather perplexing item sometimes encountered is the shingling around semicircular or segmental openings. The best method of handling this problem is very clearly shown in Fig. 51. A scale drawing of the finished opening should be provided before the work is attempted, or if that is impossible

let the workman make a rough sketch so that he will know just exactly what he intends to do. It is much easier to see where the finished work might be improved by some minor changes than it is to visualize that same finished work on the blank wall surface.

Dimension shingles with ornamental butts do not seem to be used as much as formerly. They may be obtained in octagon, circle, scallop, diamond, segment, hexagon and square butts, as

Fig. 52—Various Styles of Ornament

Fig. 53—An Example of Ornamental Shingling

Fig. 54—Design Formed with Square Butts

Fig. 55—Another Design Which May Be Formed with Square Butts

shown in Fig. 25. Besides these, other forms may be easily devised for special purposes, Fig. 53 showing a design made with specially cut shingles of two different forms. A study of Fig. 53 will show how designs of a similar nature may be easily devised.

Much of the ornamental shingling is used for the decoration of gables, and for this purpose some neat effects may be obtained by the judicious arrangement of shingles with square butts. Figs. 54 and 55 show two different examples. By an interchange of the ideas contained in these two figures several other designs may be evolved, as a study of them will prove.

(To be continued)

MISTAKES MADE IN HOUSE BUILDING

Since we have begun to live in our new home we have found that there are several misplaced rooms and some other features which are decidedly inconvenient, writes Grace C. Rutter in the *New York Tribune*. We have a neat cottage of modern style, but a casual survey gives no idea of the inconvenience and actual discomfort we are occasioned because we followed a system of false economy in the original plan.

It was false economy, because to have built in the first place as experience has shown us we should have built would have cost considerably less than to tear out now and rebuild. In addition to the money involved there would be the risk to furniture and the bother of moving it, and the discomfort of living in a house during rebuilding.

It is impossible to know how one will want everything arranged until one is actually living in the house, but one is sure of needing heat for winter and convenient placing of kitchen and laundry, and plenty of closet room.

Our heater is of the hot-water style, which has been proved to be just the thing for small homes—if properly installed. Unfortunately, our heater is too small and here begins our troubles.

We had the services of a plumber who was nearly as inexperienced in computing the amount of boiler capacity required to the square inch of air space as we were in house building.

Economize, if you must, in furniture or dishes, but do not practise this homely virtue in your heat-

ing arrangements. A plumber of experience will charge you more, but he can estimate correctly, and, if you are willing to shovel in the coal, you will be sure of a warm house.

We have a radiator in each one of the colder bedrooms, leaving communicating doors open to warm the other two rooms. Except in the coldest weather, this results in as high a temperature as people usually care for in sleeping rooms. Where bedrooms are to be occupied by old persons or little children they would need to be warmer.

Our plumber did right in so placing the radiators in each room that they would require the shortest possible lengths of pipe to connect with the boiler in the cellar.

This makes what is termed "short circulation," where as little heat as possible is wasted in the pipes. The best arrangement, when it is possible, is for radiators to be placed in the coldest corner in a room or against an outside wall and still make a short-length connection. This can rarely be done, however, as boilers are usually placed nearly under the center of a house. Where the cellar is partitioned into several rooms the heater should be put in the coldest part of the cellar.

No one should be as foolish as we were and build the cellar too small and under only the warmest side of the house. When the heater is under the coldest part of the house it assures a better draft, and, for the same reason, the chimney is better placed on this side.

If you have an undersized boiler and a shortage of radiators, as we have, you can keep fairly comfortable until the coldest days come; then you must run the heater full blast day and night and live only in the warmer side of the house.

But the most serious fault in the arrangement of rooms is our misplaced laundry, which is built in combination with a summer kitchen in an inclosed back porch. During summer it is an ideal arrangement, but in winter it is very cold for washing. If we but had another room in our cellar we would move the stationary tubs and other laundry equipment into this warm place.

An arrangement which we did not make for economy was the placing of the bathroom. It is in the upper hall, on the cold side of the house, where we thought it would be most convenient to all the bedrooms. We now find that we would be less inconvenienced if it were on any other side of the house where the pipes would not be liable to freeze (as they have done several times), depriving us of toilet comfort when most needed.

One old-fashioned plan we used in the stairways. We placed them side by side, one opening into the hall and the other into the dining room. Had we placed the front stairway a few feet farther front and the rear one opening into the kitchen and running across the back of the hall, both could have ascended to a joint landing in the upper hall. The space which the staircase now occupies in the dining room would give us several extra feet, which would be very welcome there, and the waste spaces under the two stairways, if placed this other way, could be combined in a much-needed closet. In our bedrooms there are either too many windows or they are in the wrong places. In some bedrooms it is quite a task to find a position for the bed except across a window or too near one. One is apt to forget to provide wall space for large pieces of furniture and to think more of providing enough light.

The waste product of saw mills in the United States including that conveyed to the furnaces as fuel is estimated by the Forest Service of the U. S. Department of Agriculture to be 36,000,000 cords per year and the equivalent of 2,880,000,000 cu. ft. of solid wood substance.

THE COMPLETE BUILDING EXPOSITION IN NEW YORK CITY

One feature of the National Complete Building Exposition that will appeal peculiarly to the average building contractor will be the special divisions illustrating the very latest development in commercial, factory, church and theater construction. In expanding the educational policy of the exposition it is planned to make these special exhibits as complete and comprehensive as possible, while in no degree minimizing the home-building interest which is really the fundamental idea of the show.

Much interest will attach also to the community exhibits to be put on by the several associations promoting the welfare of asbestos, tile, metal and slate shingles, hollow and self-facing tile, metal lath, cement, concrete, terra cotta, gypsum and vitrified clay products. These will be unusually elaborate and will show most effectively the possibilities of each particular material.

The exposition will be held in the Grand Central Palace, New York City, March 5 to 11, 1917, and will provide many interesting pointers for the enterprising and up-to-date contractor.

ARCHITECTS TO FURNISH PLANS FOR PLUMBERS

For several years past the relations between the various building trades in the city of Louisville and the contracting plumbers have not been all that might be desired and with a view to improving these relations the Master Plumbers' Association of the city appointed a committee to confer with architects, builders, general contractors, etc., and to report to the association. Several reports were submitted and finally the association at a meeting a short time ago unanimously adopted rules and regulations which were printed and distributed among those in the city likely to be interested.

The principal clause of the rules and regulations is that concerning the matter of furnishing plumbers with a copy of the blue prints, specifications, etc., so that the plumber can work out his bid in the privacy of his own office on big jobs which are awarded through architects' or general contractors' offices. The old system of halfway looking through plans with a dozen other men was not at all satisfactory.

A THOUSAND FEET OF LUMBER

The following letter received by a lumber company in the West and published in the *Chicago Tribune*, is likely to draw a smile to the reader:

Dear Gentlemen: In your letter to me quoting prices on lumber, let me know what you mean by M feet of lumber. Does that mean one mile of lumber? And do you lay it out and measure how much is it a mile of lumber? You know the place I want to build should not reach a mile, but should be only a little house for chickens. Be sure to let me know right away how much is it an mile of lumber. Yours very respectable,
TIM ———, Ottumwa, Ia.

The demand for building materials in Sandusky, Ohio, is said to be greater than any time before in a number of years. Dwellings and factories are going up in unusually large numbers.

EFFICIENCY OF TYPES OF FARM BARN

MUCH DEPENDS ON CLIMATIC REQUIREMENTS, AS
WELL AS UPON PRICES OF LABOR AND MATERIALS

AMONG the many interesting reports presented at one of the meetings of the American Society of Agricultural Engineers was that of the sub-committee on Major Farm Structures, and dealing more particularly with the efficiency of various types of farm barn construction. According to this committee the most efficient type depends to a large extent on climatic requirements, current local prices of building materials, labor conditions, transportation and how permanent the buildings are to be. In the southern states a structure for live stock is better without glass in the openings for light, while in the northern states glass is absolutely necessary at least during certain months of the year.

THE TWO TYPES

It is therefore necessary to divide the construction into two types; one for the northern and one for southern conditions. This again may be divided into several types to suit the local material and labor conditions.

For rectangular barns the arrangement of two rows of stalls running lengthwise of the barn has been found most desirable because the side walls paralleling each row furnish better light. Such an arrangement is a saving of labor because two rows can be attended to at once in caring for the stock.

The side walls of a building containing live stock must be substantial and permanent and so constructed that large openings can be had for doors and windows without materially weakening them; also they must contain vertical ducts for ventilating flues.

WINDOW OPENINGS

The window openings and ventilating flues are as important as the walls themselves. The live stock can live without walls but not without light and air. The area of window and flue space required in proportion to the area of side wall will depend upon the area of side wall and the number and kind of stock to be housed.

Let us therefore consider the window requirements for this arrangement. Dairy cows placed in rows take up an average stall width of $3\frac{1}{2}$ ft. per head and for each cow at least 4 sq. ft. of window glass surface should be allowed. Therefore, each $3\frac{1}{2}$ ft. of wall length should contain 4 sq. ft. of window glass, which makes an average of $1\frac{1}{7}$ sq. ft. of glass per foot of wall length. The windows should be of such height that they can be spaced far enough apart to admit the required materials to give strength to the walls and also to allow ample space for ventilating flues.

The flues should run in a vertical position in order to perform their functions and should termi-

nate at certain locations in the room running as directly to these points as the arrangement of the room will permit. In order to keep the room free from unnecessary obstructions it has become general practice to build these flues into the side walls where they will be out of the way.

COST OF TYPES COMPARED

There is no question but what concrete, tile, brick and steel will always be the most permanent, and in the long run the most efficient materials to use for the construction of farm buildings. The farmer, however, who is forced to buy cheap land cannot be persuaded to consider concrete or tile as long as the cost of wood construction will keep down the cost of his necessary farm improvements.

For the purpose of determining the cheapest form of construction the following types with estimates of their costs have been compiled, all based on one given market price for materials and a uniform cost for labor. The estimates may be too high for one locality and too low for another, but the same proportion of cost would remain the same for the various types of construction. Comparing the cost and efficiency of three types of frame building we find that the plank frame type of the two-story construction costs about \$324 per bent of 12 ft. length, which is equal to \$27 per running foot.

The braced rafter type of the two-story construction figures \$24 per foot. The one-story construction costs \$15 for the stock shed and \$6 for the hay shed, making a total cost of \$21 complete—a saving of 12 per cent on the braced rafter construction and 22 per cent on the plank truss construction.

Considering the efficiency of the one-story barn from the point of labor, the hay being stored on the same ground level of the stock, there is a saving of labor in filling the mow because the hay track is 10 ft. nearer the ground, this resulting in a saving of about 30 per cent of the hoisting of hay to the rack.

THE ONE STORY BARN

From a sanitary point of view, the one-story barn is much better because there is less danger of contaminating the hay and feed supply if stored in an adjacent shed than if stored directly over the stock, no matter how well the mow floor is built.

More dust is excluded by eliminating the chute, and less odors from the stock will reach the hay.

The risk of fire is lessened because flames and heat from the burning hay shed will not reach the stock as quickly, thus giving more time to drive the stock to safety.

The risk of storm is less because the stock is not in a low building and the hay barn does not extend so high in the air.

The hay shed built to the north of the stock barn

and at right angles to it, forming an "L," gives protection from north winds for the stock barn and exercising lot.

By the proper use of air spaces and building paper the one-story barn can be made just as warm as the barn with the hay above the stock.

The one-story barn will admit making the ceiling higher in the center so that air can be taken out at the highest point in the summer. The higher ceiling also gives more cubic feet of air in the barn per animal.

The committee recommended in its report the following dimensions in connection with barn construction:

Minimum width of barn 32 ft., width of stalls from 3 ft. 4 in. to 4 ft., according to the size of cows.
Cows headed in: Minimum width of central feed alley 6 ft. Width of mangers, minimum 24 in., maximum 40 in. Length of stall from stanchion to gutter, minimum 4 ft. 6 in., maximum 5 ft.
 Width of gutter, minimum 18 in., maximum 24 in. Width of litter alley, minimum 3 ft. 6 in.
Cows headed out: Width of feed alley, minimum 3 ft. Mangers, minimum 26 in., maximum 40 in. Length of stall from stanchions to gutter, minimum 4 ft. 6 in., maximum 5 ft.
 Width of gutter, minimum 18 in., maximum 24 in. Width of central litter alley, minimum 7 ft. Thickness of concrete floor, minimum 6 in.

Where the cows are headed in, the central feed alley may be raised to the top of the manger or made level with the stall floor as desired. The stall floor should slope to the rear not less than $\frac{1}{4}$ in. per foot. It is an advantage to construct the stall floor on a bias varying from 4 ft. 6 in. to 5 ft. 2 in. in width. This will make it possible to place a cow in a stall according to her length. A slight depression in the floor of $\frac{3}{4}$ in. to 1 in., about 14 in. from the manger curve, will aid in retaining the bedding under the animal's front feet and will prevent them from falling in reaching for food.

The feed alley should have a slight slope toward the point selected for the drain. The surface, if made of concrete, should be troweled as smooth as possible. A smooth feed alley with no corners to hold food prevents them from becoming sour. The gutter should slope crosswise toward the litter alley, to give better drainage and lengthwise toward a drain connected with the manure pit, to be used principally for flushing and washing the floors.

PROTECTION OF SEPTIC TANK OUTLET FROM FROST

A question which frequently comes up to those who are providing septic tanks to dispose of the waste from their buildings is the means of protecting the distributing lines from frost. As a rule, these pipe lines are so laid that there can be leakage of the effluent from the tank at the joints all along the line. In Bulletin No. 14 of the Iowa State College an illustration is given showing the arrangement of sand filters where the piping, 4 in. in diameter, is laid in a trench $8\frac{1}{2}$ in. deep and $11\frac{1}{2}$ in. wide, filled in with coarse stone, then covered over with sand to a depth of 2 ft. 6 in. to the center of the drain pipe. The covering is sand, and at the end of the distributing pipe a 4-in. riser comes above the ground. These pipes are laid about 5 ft.

on centers, and the bed, before the sand filling is put in, is dug out so as to form a ridge between two different lines.

The Bulletin states that in order to prevent the freezing of the sewage on the surface and sealing the filters, rendering them inoperative, the filter beds are usually ridged for cold weather operation so that when the beds are dosed the sewage flows in gutters formed between the ridges. If freezing takes place, the ice formed on the top of the sewage remains suspended on the ridges, and the succeeding doses of sewage will flow underneath the ice. The ridges should be thrown up every 3 or 4 ft., and not be any higher than necessary to prevent freezing at the surface of the bed. At the close of the cold period the valleys between the ridges may be freed from all deposit or scum before leveling down to the ridges for warm-weather operation. All dirty sand should be removed at this time. This method, used in Iowa, will be of interest to men who have to arrange septic-tank systems in all parts of the country.

CHICAGO'S ONE-ROOM APARTMENTS

The one-room apartment seems to have received the decided approval of the Chicago apartment dweller, for within the short time that has elapsed since its introduction into that city a number have been built, much thought and time having been devoted to secure an economical division of space. The entrance door of one of these apartments opens into a small vestibule, which contains a closet. Directly in front of the entrance door is the bathroom, 6 x 11 ft., containing a built-in dressing table and linen case, so that it can be used as a dressing room. At right angles to the entrance door is the living room,

FLOOR PLAN OF ONE-ROOM APARTMENT

13 x 16 ft. This contains a kitchenette, 2 x 8 ft., built into the wall and including a gas stove, ice chest and sink, all of which are concealed by curtains. A built-in bed is placed against the bathroom partition, and when not in use it is shut in by French doors and mirrors. A sun parlor or balcony, 7 x 10 ft., is semi-divided from the living room. The type of one-room apartment herein described was designed by Roy F. France.

"KINKS" FOR THE BUILDING MECHANIC

SOME "SHORT CUTS" AND "WRINKLES" WHICH
THE PRACTICAL MAN WILL FIND VALUABLE

BY W. S. WILKIN

THE suggestions which are here presented relate to various matters which the carpenter and the builder often find useful in their work. Referring to the diagrams, Figs. 1 and 2 illustrate a practical method for drawing the arc of a circle without a center. Sometimes in making a new street in his town the carpenter is called upon to construct a "form" for the crown of the thoroughfare. I have seen used boards 16 ft. or 18 ft. long with only a few inches crown, and it would take a long radius to lay it off with a rod and trammel points. In fact, it would be necessary to have lots of room, to say nothing of a rod 30 ft. or 40 ft. long. By using the method here shown it can be laid off on the bench.

Referring to Fig. 1, lay off the chord on the edge of the board, as from *c* to 7, then square across the board at each end, as at 7-*f* and *c-e*;

Fig. 1—Method of Drawing an Arc When the Radius Is Too Long to Permit of Ordinary Methods

Fig. 3—Method of Drawing a Small Circle by Means of the Steel Square

also in the center *b-a*, and mark the height of the segment at *a*. Draw a line from *a* to 7 and from *a* to *c*. Then draw the line 7-7' perpendicular to *a-7*, and *c-d* perpendicular to *a-c*. Now draw the line *d-7'* passing through *a*. Divide *b-7* into any number of equal spaces, in this case seven; then divide *b-c*, *c-e*, *d-a*, *a-7'* and 7-*f* into the same number of equal spaces as shown.

Now draw 1-1, 2-2, 3-3, etc.; also *a-1'*, *a-2'*, *a-3'*, etc. Drive a nail at the intersection of 1-1, with *a-1'*; also at the intersection of 2-2 with *a-2'*, etc. Bend a thin strip around the nails and mark around this with a pencil and the result is a curve that is almost, if not quite, a perfect arc of a circle.

There are several other ways of doing this, and one is shown in Fig. 2 which I think is very good. Square across the center of the board and make the height of the segment at *c*; then lay off the length of the chord on the edge of the board, as at

a-b. Now with *d* as center and *d-c* as radius draw the arc *c-e*. Divide *d-e* into any number of equal spaces—in this case seven; then divide the curves *c-e* into the same number of spaces and draw the lines 1-1, 2-2, etc. Divide *d-b* and *d-a* into the same number of equal spaces and draw the line 1'-1' parallel to the line 1-1; the line 2'-2' parallel to 2-2, etc., both ways from the center as shown.

Make the line 1'-1' the same length as 1-1, and the line 2'-2' the same length as 2-2, etc., as shown. This may be done by taking the rule and pencil and using them as the marking gage which

Fig. 4—Method of Drawing An Ellipse by Means of the Steel Square

Fig. 2—Another Method of Drawing Large Arcs

every carpenter knows how to do; then stick the nails and draw the curve as in Fig. 1.

In Fig. 3 is shown the method of drawing a small circle with a steel square. Let *a-b* represent the required diameter. Drive a nail at *a* and also at *b*; hold the pencil at *c* and with the square close against the nails slide it around and *c* will trace the curve; reverse the square and draw the other half.

Fig. 4 shows how an ellipse may be drawn with the steel square. Suppose we desire to draw an ellipse with a major axis of 40 in. and a minor axis of 24 in. We would proceed as follows: Lay off the major axis *c-d* and the minor axis *e-f*. Drive a nail at *a* and then another nail at *b*, which is 8 in. below *a*, making *b-e* equal to *c-a*. Place the square as shown by "A" and hold the pencil point at the 20-in. mark on the inside edge of the blade; move the square around, keeping the blade

and tongue against the nails, as shown in its position as indicated by "B" until the 20-in. mark is at *c* and the blade rests against the nails. Reverse the square and draw the other quarter, then pull out the nail at *b* and drive at *g*, making *g-f* equal to *c-a*. Draw the lower half in the same manner.

In Fig. 5 we show another way of drawing an ellipse which often will be found handy. It is not exactly a true ellipse, but it makes a very pretty curve and for some things I like it better than a true ellipse. Make *a-b* and *d-c* equal in length to the major axis, and *a-d* and *b-c* equal in length to the minor axis. Divide *e-b* into any number of equal spaces and number them as shown. Divide *b-f* into the same number of spaces and number all as clearly indicated. Then draw a straight line

Fig. 5—Another Useful Method of Drawing an Ellipse

Fig. 6—Pattern for a Table Top

from 1 to 1, from 2 to 2, from 3 to 3, etc., repeating the operation for the other three quarters. The closer the divisions the better will be the curve produced.

We show in Fig. 6 a pattern for a piece of furniture such as a taboret top or something of a similar nature. Several years ago a boy came to me in the shop with a pattern like this and wanted to use three kinds of wood for it. One was white pine, and I do not recall the other two; however, black walnut and mahogany would serve an excellent purpose. He wanted to know how to find the bevels and cut it so as to make a good job. This is the way I did the work.

When I am engaged in the shop I usually have on hand a nice smooth board, something like that shown in Fig. 7, with one edge jointed straight.

With the marking gage I ran a line about $\frac{1}{4}$ in. back from the straight edge, as shown at *a* and *b*. I used this to set the dividers or compasses in as it is practically impossible to set them right on the edge of the board. I took the square and squared across the board as at *c-g* of Fig. 8; then with *c* as center and any radius I drew the arc *e-i-h*. Next with *e* as center and the same radius I cut the arc at *i*, and then drew a line from *c* to *i*. The angle *h-c-i* is just 30 deg., which is the angle required to cut the pieces.

Set the T-bevel with the stock along the straight edge of the board from *c* to *h* and the blade on the line *c-i*. Cut the pieces shown in Fig. 8 and joint the edge *a-b* straight. Then apply the bevel with stock along the straight edge and the blade across the board at *c-d*. Mark along the edge of the blade with the point of a knife. The miter box will probably not cut this angle without putting in a form. Cut off a board at 45 deg. and clamp it in the box, then put in the piece with the straight edge against the 45 deg. cut and set the edge of the saw in the knife mark *c-d*. Now cut one end of all the pieces, then turn them over end for end

Fig. 7—Board for Use in Patterns Like That Shown in Fig. 6

Fig. 8—Diagram of How to Find Some Common Angles

keeping the straight edge against the board and obtain the length *e-c*. Set a stop and cut them all on that end. This will gage the width in the center of the piece.

The boy cut the pieces this way, and did not touch them with a plane, obtaining a fine fit.

The way to put this kind of work together is to glue them on a piece of paper face down and let them dry; then glue them on a board, paper side up, clamp them down until dry; scrape off the paper and then smooth off the pieces.

On the left end of the board, Fig. 8, I show how to find some of the angles commonly used. With *c* as center and any radius draw the arc *d-f*; then with the same radius and *f* as center cut the arc at *j*; this is 30 deg. from *d* as shown. With the same radius and with *d* as center cut the

arc at k , which is 60 deg. from d . Now with f as center and any radius draw an arc at m . Again with the same radius and d as center draw another arc intersecting the first one at m . Draw a line from c to the intersection of the arcs at m , and this will be 45 deg.

Now with any radius and d and l as centers

draw arcs intersecting at n . Draw a line from c to n and it will be 22 deg. 30 min. from d . Again with any radius and f and l as centers draw arcs intersecting at o . Draw a line from c to o , which will be just 67 deg. 30 min. from d . In this way angles that are very accurate can be found in a very few minutes.

SUGGESTIONS FOR PAINTING STUCCO HOUSES

SUGGESTIONS WHICH WILL BE FOUND OF VALUE TO THE BUILDER OF HOUSES OF THIS KIND

GRAY and pea-green is a color scheme for plaster houses which seems to be meeting with much favor at the present day. The houses, with their casement windows and long-stretched English lines, their excellent solution of the piazza problem and their artistic use of plaster, also have a distinct color appeal. One recently noticed has exactly the same color scheme as that of the small shingled house except that its door is pea green and it has an additional touch of pea green in its window boxes. A happy touch of ecru is introduced in its novelty net curtains, hung in straight lines.

Another plaster house is of dull yellow plaster, with a black roof and grayish black shutters. Its walks are of narrow red bricks and its curtains of corn-colored silk. Still another plaster house is natural gray, with the half-timbered woodwork and also the gateway hood of grayish black. The walls and piers are of brick. The touch of red introduced in this way is like a note of genius.

THE PERSONALITY OF THE ARCHITECT

A well-known American architect has a house of creamy white plaster, with grayish black eaves and structural timbers, white sashes and blue window casings, doors and blinds; and that strange blue is said to be the very mark of his genius, the touch that expresses his personality.

These various color schemes are mentioned because we are building more and more of plaster and some of us do not live near the work of the best architects, says a writer in *The Dutch Boy Painter*. The way to study the painting of houses is to get your knowledge at first hand from the work of the best men. There are few ways that we can so directly show practical appreciation of art and of civics combined as by properly painting our houses.

MISTAKES OF THE SMALL HOUSE

The small house of different materials for the first and second floors makes many mistakes in color. If the first floor is of red brick and the second of shingles, brown would be a restful color for the shingles. If the first floor is of clapboards and the second of shingles, white clapboards for the first floor and dark green shingles for the second floor and roof are good. All the first-floor trim should be in white and all the second-floor trim except the sashes should be of dark green. If the first floor is

plaster and the second floor shingles, gray for both, with trim of light bluish green, would be attractive.

Do not paint clapboards red. Do not use one color for clapboards, another for shingles, a third for trim, a fourth for roof and a fifth for chimney. Many houses are painted that way, and one may even see two different colors for the first and second floor parts of the chimney, with another color introduced on the window boxes. And the people who live in such houses are not ignorant people; they are very often well educated, well dressed, and well meaning. They have never looked at the color of their houses as an ethical or aesthetic problem.

RESPECT FOR WELL-PAINTED HOUSES

"Painting the house" seems a commonplace affair, but if we can do it uncommonly well, we shall learn to feel for it the respect we pay to so-called higher forms of art. We make too great a distinction between the fine and useful arts. The true art is that which is born from an enthusiasm for beauty and that, like charity itself, gives its best to the needs of our every-day life.

TALLEST OFFICE BUILDING IN BROOKLYN

Since our last issue went to press plans have been filed for a twenty-two story store and office building to be erected on the site of the old Dime Savings Bank Building at the southwest corner of Court and Remsen Streets, Brooklyn, New York, and which sets a new standard of height for office structures in that city. According to the plans which have been prepared by Architects Starrett & Van Vleck, the exterior will be of limestone and granite for the first four stories above which the facade will be of face brick trimmed with limestone. The roof will be of red tile. The cost is estimated to be in the neighborhood of \$500,000.

As indicating the wide circulation of the BUILDING AGE and its value as an advertising medium, it is interesting to note an inquiry which was received by the Arkansas Soft Pine Bureau, Little Rock, Ark., from a concern in Camperdown, Sydney, New South Wales, referring to its page announcement in the July number of the paper.

SOME TRICKS OF THE BUILDERS' TRADE

CONSTRUCTION UNDER PORCHES—STORING AND HANDLING TRIM WHEN PLASTERING—THE CELLAR STAIRS

BY JAMES F. HOBART

FOR fifty years I have in my leisure time been looking around for new kinks and methods, and the number I have seen would, if all were stacked up together, prove most amazing. I like to take little trips among the new houses in process of erection and note how many new things I can find—new to me at least. Only a short time ago I took such a trip and went into six new houses, finding ten new things which interested me.

ARRANGEMENT OF THE STUDS

In the first house visited the partitions were set ready for the lathers, and the manner in which one closet was studded brought to mind the question, "Why do some walls crack?" After looking at the partition a second time the thought came to me, "Why do not more partitions crack?" In Fig. 1 is shown the manner in which this partition was erected, and it surely was "hung from nothing and stood on a thin floor." The studding which formed part of a closet wall shown at *F*, *G* and *H* were set at the bottom upon two pieces of 2 x 4-in. stuff, which pieces were simply toe-nailed between two of the floor beams. At least studs *F* and *G* were thus set, while the double stud *H* was placed upon a piece of 2 x 4, which was laid on top of the floor joists instead of being cut in between them. This was well enough so far as the stud *H* was concerned, and the lath and plaster of the wall also stiffened this particular stud. The studs *G* and *H* were mounted upon a couple of spring boards, while at the top they were fastened to nothing at all. True, they were nailed to a piece of board shown at *D*, this board being nailed on its edge and, at either end, to a floor joist and to strips *D* and *E* respectively. These strips were only 2 x 2 in. (really only 1½ x 1½ in. actual measurement), and while the board *A* was supported upon both edges by the strip *E*, the other end attached to strip *D* had nothing whatever to support itself and the board at the line of the studs save the stiffness of board *A* and strip *D*. As the board was split the way of the grain little support could be expected for studs *F* and *G*, which were practically free to "go and come" with the floor as weight was placed upon and removed therefrom.

SOME CAUSES OF CRACKS

Is it not to be expected that the wall paper and the plaster, too, would crack all up and down along the edge of stud *G*? We all have seen cracks in similar locations in buildings and often wonder why the cracks appear and what caused them. The construction here described would cause cracks in any house.

The manner of supporting the front porch or piazza floor when the latter is to be of concrete with brick balustrade is frequently a problem which vexes the builder more than a little. It is usually necessary that the foundation for the front wall should be run down the same depth as that of the cellar wall and other walls. Some times the side foundation walls may be stepped up and a shallow foundation put in for the front of the piazza construction, but such is not always the best way. When this method is employed it is well to fill the space under the piazza floor with cinders, gravel or whatever material is most handy for the purpose.

UTILIZING SPACE UNDER PIAZZA FLOOR

There is, however, a considerable amount of space underneath the piazza floor, which if saved, could be utilized for storage and for many other purposes, not the least of which is the growing of mushrooms. While on the trip in question I came across a row of houses, each of which was being built with a dark, fully inclosed space under the entire front piazza, leaving a fine space about 6 ft. one way by 18 ft. the other and 7 ft. high. In Fig. 2 is shown the manner in which the floor was supported while the concrete was hardening. The space under the porch was laid with a concrete floor, but as it was very soft a couple of planks were put down at either side as at *A* to support the 2 x 4-in. posts *B B*. Ledgers were tacked on at *C C C C* to stiffen the posts, which were spaced about 4 ft. apart. Braces *E E* were nailed to each pair of posts to support the middle of the 2 x 4-in. beams laid flatwise, and upon these beams was placed a floor of ⅞-in. shingle strips as at *F F*. On top of the boards building felt was laid down to make tight against water from the concrete. Some 5-in. I-beams were laid in as shown at *H* and blocked up on the concrete walls at either ends of the beams. The latter was spaced 5 ft. 6 in. on centers, and no beam was placed at either end of the porch floor, the block wall being sufficient to support the floor slab. In some of the houses reinforcing material was laid in between the flanges of the I-beams, particularly in that portion immediately in front of the door. In other houses no reinforcing material was used in addition to the I-beams as the thickness of the porch floor, 8½ in., was deemed sufficient to carry any load likely to be placed upon it.

CONSTRUCTIVE DETAILS

Around the outside of the porch wall "forms" were rigged up as indicated at *K*, these consisting of a plank 8½ in. wide and fastened lightly to the piece *M*, which was another plain scantling. Two

corners, *L*, were then fastened in place and the brace *N* placed underneath. In fact a brace was put in as often as was found necessary to hold the form in place, these varying from 4 to 6 ft. in the work I examined. As it was found somewhat troublesome to cut the braces *N* as wanted to just the right length to level the form *K*, the expedient was tried of putting shingle wedges between *M* and *N*. This trick worked well and made leveling easy.

The concrete was then placed and leveled off to the dotted line *J*, and after setting the "form" *K M* was removed, but the inside support was left until the porch floor was three weeks old, when it was removed by taking out the braces and ledgers, which were the only pieces that had been nailed. The posts *B B* in Fig. 2 were set out a little from the foundation wall, for the purpose of passing ropes around each remaining post after all had been removed save barely enough on one side to hold up the floor at *F*. With a man at each rope a quick

Fig. 1—A Badly Supported Partition

and strong pull together drew out the remaining stud on one side of the floor, the rope-pulling being done through a doorway leading to the main cellar of the house. As the remaining posts were pulled out together, down came that side of the false floor and the remaining posts, beams and floor boards were easily picked out and removed, leaving the under porch cavity clear for mushroom growing or for any other purpose.

If the designer of any house wishes posterity to "rise up and call him blessed" let him put windows in the principal closets. These need not be expensive, as a plain box casing costs but little to put in, glaze and hang, although it is very desirable that the sash in closet windows be made removable. Closet windows as a rule do not mar the effect from the outside, even when such windows are located close to other and full-size windows. The small window necessary for a closet seems to permits its use almost anywhere in the structure without ill effect. When small odd windows are to be cut in to light closets the writer would suggest that they be made for sash not larger than 15 x 21 in., and that

they be so placed that they align with the tops of the full size windows nearest to them. If this is done such small window openings are seldom objectionable.

The recent windy weather in Indiana played havoc with the plastering and made necessary a considerable outlay for muslin window frames so as to keep the drafts off the green plaster. One contractor hit upon the novel expedient of procuring a lot of cheap burlap which was cut to size somewhat larger than the window openings and a piece spread over each window and held in place by four laths and three small nails in each lath. When not required any longer the cloth was quickly removed by drawing the nails, and fifty pieces could be quickly carried from one job to another by stuffing them into a meal sack. The transportation of the muslin frames from one job to another is always accompanied by considerable loss by breakage of frames and tearing of muslin, but the burlap will stand harder usage and, not being attached to a frame, does not get torn. Again the burlap can be cut to such a size as to fit almost any window opening, whereas the muslin frames must be made to order to fit the individual windows, or cut over

Fig. 2—Construction Under a Porch

to smaller sizes as required, and once a frame is cut down it is of no use for the large windows.

Several times during the trip in question I was forcibly struck by the exceedingly small size of the rooms in a number of the houses. In many instances it seemed as if the sole effort of the designer had been to get as many rooms as possible under the same roof so that the rental might be based on a 10-room house, even if the building covered only space enough for seven rooms of normal size.

What to do with the floors when the plasterers began operations is a problem which keeps many builders guessing in Indiana as well as elsewhere. In low-priced houses it is almost a vital necessity to put down a match board floor as soon as the studing are in place, the roof put on and before any of the partitions have been set. This materially lessens the first cost of the floor, but how to keep the floor in presentable condition during the plastering and painting is a problem which has been met in various ways. Perhaps the most common one is to cover each floor with an inch or two of clean sawdust

and then clean it all out after the plastering has been done. This, however, has its drawbacks, for plaster dropped in the sawdust cannot be picked up and used again as can plaster which falls upon a floor. Hence there is a considerable waste of plaster by the sawdust method. Another plan of floor protection found in frequent use in Indiana is to cover the entire area with a good quality of building felt and fasten the laps of the paper with lath cleats placed continuously over the joints. In the better class of houses where the floors are laid after plastering the walls a temporary floor of 6-in. low grade boards is often placed upon the joists for the workmen to use during construction. This floor is all removed before the permanent one is placed. Hence the boards forming the temporary floor and placed 2 or 3 in. apart so that all the sawdust, dirt and waste plaster falls through. This practice, however, leaves all kinds of dust and dirt upon the ceiling plaster and must add materially to the fire risk. The leaving of sawdust and shavings between the floor joists of a new house does not appeal to me as good practice, and there is no satisfactory way of getting the dirt out without damaging the plaster clinches, for if one sweeps hard enough to remove all the dirt he will surely do damage to the plaster.

A SECOND FLOOR SLEEPING PORCH

At one house they had just thrown out a second-story sleeping porch with four windows on the side and two windows at each end. The windows took up about all the room there was and left only space enough between them for the weight pockets. Only a single sash was to be used, and the frames were made with pockets for the sash, much the same as are used in street cars, where in order to lower the sash it is first necessary to raise it a trifle, swing it inward and then drop the sash into a pocket in the window stool. In these window frames the jambs extended down to the bottom of the sash pockets and the bottom sash was framed in at that point. The body of the porch was closed to about the height of ordinary chair molding, the outside being shingled upon 4-in. boards placed 2 in. apart and covered with building felt. The inside of the porch was to be plastered above and below the six windows, which occupy the entire wall space except room for three studs—two at the corners and one between the side windows.

The builder sometimes finds himself with a good bit of trim on the job when the house is to be plastered. If he leaves the trim on the piazza or in one of the rooms the masons will probably do all sorts of things to the fine lumber, for the plaster mason on any day in the week would rather have a nice clean board to use than one of his mortar-daubed culls which he brings with him. In this house the carpenter had evidently "been through the mill," for he had selected a place in the cellar just opposite one of the cellar windows where he nailed four hangers to the floor joists and then nailed a cross piece to each pair of hangers so that he could pass the trim right in through the cellar window and pile it close and tight under the floor of the build-

ing. When the carpenter came back after the plastering was finished he found his trim all safe, sound and clean, and he could get the piece he needed either through the cellar window or through the cellar itself. It was one of the nicest and best for storing and handling trim that I have yet seen.

In another house the cellar stairs were planned right in the middle of the cellar and ended directly against the middle of the cellar wall. In fact the last tread would touch the wall. The architect, however, got out of this predicament neatly and with credit. He cut off the stairs high enough—about three or four steps—to allow of a square platform the width of the stairs, then he designed a short run of steps on either side of the platform so that one could turn either to the right or left as he went up or down the stairs. The treatment of the cellar stairs looked much better to the writer than the putting in of a winding stair, and of course getting the turn invariably in the wrong direction.

ELECTRIC ICELESS REFRIGERATION

Electric iceless refrigeration has been installed in the Martin apartment building at 191 East Walton Place, Chicago, Ill., of which Howard Shaw was the architect. The system consists of a refrigerating machine, driven by an electric motor which circulates ammonia through cooling coils. A brine tank is placed in the ice receptacle of a good ice box and connected by insulated piping to the machine, which may be placed either in the lower compartment of the box for a small family or in the basement of an apartment building where several boxes are in use. The size of the machine is increased with the number of boxes in the building. There are no complicated parts, and the machine can be started and shut off as easily as drawing water from an ordinary faucet, for in very hot weather, when the thermometer reaches 90 deg., the machine may be kept running for a period of about five or six hours in every twenty-four, which will keep the interior of the box at about forty degrees. It has been figured out that if this box requires the equivalent of 150 pounds of ice daily the entire cost of electric operation will amount to \$5 or \$6 per month. The same refrigerator supplied with 150 pounds of ice daily, it is stated, will maintain a temperature in hot weather never below 50 deg., will cost considerably more to operate and that with the uncleanness and waste. The *Economist* states that it has been the general opinion that electric refrigeration was much more expensive than the use of ice. If this is not true it would be well worth while for builders of apartment houses to investigate the matter and see what can be done about its application, because of its economy and its convenience.

In Colonial times it was the custom to build two log houses side by side rather than to construct one large one, owing to the difficulty of handling large logs, says *Hardwood Record*. Sometimes they remained separate houses, but with a common roof over them, the space between often being closed by weather boarding.

BUILDING SEGMENTAL BRICK ARCHES*

OBTAINING CORRECT SIZES OF BRICK TO BE USED—VARIOUS STYLES OF ARCHES

BY W. H. HEFELFINGER

IN Fig. 8 is shown a segmental arch laid up with stretcher brick. These brick should be cut wedge-shaped to make the most finished job. To get the shape and size of these brick, place two bricks on the segment, as shown in Fig. 8, B-1; measure the distance between them at the top, allow a little for heavier joint at top than bottom, and the remainder will be the amount to cut from the brick. Mark the brick as shown at B-2, Fig. 8, and cut off the part marked X with a chisel. Cut one half of brick on one side and one half on the other side,

be either cut or ground, and the quickest way is to first make a pattern to mark them. There are several ways of getting the size of this pattern. One way is to make a full-size drawing of a part of the arch, lay off the size of brick and joint on extrados, run these lines to the center, and then measure the thickness of the brick at the intrados. Another way to find the size, and probably the most practical, but more liable to error, is to lay one course of brick to the center, then stretch a line from center point to upper corner of brick at extrados, and

Fig. 8—A Segmental Arch Laid Up with What Is Known as "Stretcher" Brick

Fig. 9—Method of Laying a Three-Ring Arch

Fig. 10—Another Method of Laying Segmental Arches

and always lay cut side up; that is, cut side toward center of arch, as it keeps the soffit smoother.

Figs. 9, 10, 11 and 12 show some of the other ways of laying segmental arches. Fig. 9 shows a three-ring arch, and cross-section B shows construction over frame, and C shows bonded soffit. Any of the others may have bonded soffits also.

Fig. 13 shows a bonded semicircular arch. This arch is one whose intrados and extrados are half circles. The brick for an arch of this type must

where line crosses brick at intrados you will have size of brick. See O, in Fig. 15.

The best way is to figure it out mathematically, as follows: Find the length of extrados, which is half the circumference of circle; divide this by thickness of one brick and one joint, which will give number of course. The number of courses should be an odd number, so they will bond at the center. It will hardly ever come out even, but difference may be made up in the joints. Find length of intrados, divide by number of courses, subtract size of joint, and you have size of brick.

*Continued from page 39, October issue.

To make this explanation clear I will apply rules to Fig. 13, which arch has a span of 3 in. and a depth of $12\frac{1}{2}$ in. Length of extrados equals half of $3\frac{1}{7} \times 51$ in., or 8 ft. Figuring each joint and brick as 3 in., it will take 32 courses, but as we must have an odd number, and joints are rather large, we will make it 33. Length of intrados equals half of $3\text{ ft.} \times 3\frac{1}{7}$, or 4.725. Divide this by number of courses, and we have 1.72 in. Subtract about $\frac{3}{8}$ in. for a joint, and we have about $1\frac{3}{8}$ in. for brick at intrados.

After having determined the thickness of brick at the intrados, a pattern, as shown in Fig. 14, may be made. *A* equals the thickness of brick, and *B* equals calculated thickness of brick at intrados.

to come out right. These points also act as guides in laying the brick.

Arches of this type are seldom cut all the way through unless the soffit and both sides of the wall are finished, but built as shown in section of Fig. 13. Figs. 16 and 17 show several other types of semicircular arches, three-ring rowlock and one-ring stretcher.

BUILDINGS OF "MILL CONSTRUCTION"

"Heavy Timber Mill Construction Buildings" is the title of a comprehensive publication just issued for architects and builders by the National Lumber Manufacturers' Association, and written by E. C.

Fig. 11—Still Another Style of Segmental Arch

Fig. 12—A Fourth Method of Laying Segmental Arches

Fig. 13—Elevation and Vertical Section of a Bonded Semicircular Arch

In an arch of this kind we have four different shaped brick. Nos. 1, 2, 3 and 4, on drawing in Fig. 14, show where to place the brick to get the right size, and numbers in Fig. 13 show where they are laid. The pattern should be laid out on both sides of the board, as each side requires a different pattern on account of cut face being laid up. In laying up an arch of this kind always use a line as shown at *D*, Fig. 15. After laying up about five courses, measure them, and space off that distance on the center from the wall on each side, points *A*, Fig. 15; then measure remaining space to see if it comes out right. Sometimes it becomes necessary to vary the spaces a small amount

Paul, construction engineer, Chicago, Ill. In explaining the subject matter, the following statements are made:

"The term 'mill construction,' as commonly used, is the name given to that type of building construction in which the interior framing and floors are of timber arranged in heavy, solid masses, and smooth, flat surfaces, so as to expose the least number of corners and to avoid concealed spaces which may not be reached readily in case of fire.

"A broader interpretation of the term includes the meaning given above and adds the specification that the building shall be so constructed that fire shall pass as slowly as possible from one part of

the structure to another. This means that each floor should be separated from all others by incombustible walls or partitions and by doors or hatchways which will close automatically in case of fire near them. Stairways, belt passages and elevator shafts are encased, or preferably located in fireproof towers. Openings in floors for passage of belts, etc., are either avoided or fully protected against passage of fire or water. The proper installation of an approved automatic sprinkler system is of great importance. Ceilings in rooms where highly inflammable stocks are kept, or where hazardous processes are followed, should be protected by the use of a fire-retardant material, such as plastering laid on wire lath or expanded metal. The ceiling

Fig. 14—Details of the Pattern for Obtaining the Correct Size of the Brick

Fig. 15—Wooden Center for Laying Up an Arch

should follow the lines of the timbers without an air space between the two surfaces.

"Mill construction has always been looked upon with favor for buildings in which ordinary manufacturing industries are carried on. Warehouses, and buildings for storage of merchandise, stores, office buildings, factories, shops, and all buildings of moderate height which are not to be used for extremely hazardous purposes, from a fire-protection standpoint, are later developments of this type of construction. City building codes limit the height of building and size of open spaces in buildings. They also specify the minimum sizes of timber which shall be used, and other similar details."

An idea of the building activity in Baltimore, Maryland, may be gleaned from the fact that one day in October three concerns made applications for permits to erect sixty-two dwellings estimated to cost \$115,600.

HANDBOOK FOR ARCHITECTS AND BUILDERS

The nineteenth annual edition of the "Handbook for Architects and Builders," edited by Emery Stanford Hall, and the official publication of the Illinois Society of Architects, under whose auspices it is issued, has just been distributed among the membership of the Society. The publication aims to provide under one cover information which the architect requires daily and, although intended primarily for architects practising in Illinois, it contains matters of interest to builders everywhere.

The contents include a list of architects licensed to practise in Illinois, a copy of the Chicago building ordinance, together with special rulings of the

Fig. 16—Detail of a Three-Ring Row Lock Arch

Fig. 17—Details of a One-Ring Stretcher Arch

building department of that city, standard specifications of hollow tile fireproofing, standard specifications for concrete work, together with valuable information concerning concrete construction, heating and ventilation, office practice recommended by the Society, architectural acoustics, several new tables by Winslow and Mensch on concrete construction, the Orders of Architecture, together with many other tables and formulæ of special value to the architect and builder. A comprehensive index facilitates reference.

A series of tests has just been carried out by the British Fire Prevention Committee, the results of which tend to prove that sawdust intimately mixed with bicarbonate of soda and applied in bulk has certain advantages over sand and similar materials for putting out comparatively small fires caused by the ignition of the vapor of petroleum spirit and other inflammable liquids.

A SUBURBAN HOUSE OF SEVEN ROOMS

CENTRAL HALL AND LIVING ROOM NOTICEABLE FEATURES—VARIOUS DETAILS OF CONSTRUCTION

WE have taken for the basis of our colored supplemental plate this month a Colonial residence of seven rooms and bath, finished on the exterior with siding and with roofs covered with shingles. The chimneys are of brick with the exposed portions finished with stucco designed to match in texture the base around the house which is also of stucco finish.

FOUNDATIONS AND FRAMING

The 12-in. foundation walls are to be built of brick and have a finish above grade of two-coat stucco work. The framing timbers are to be 2 x 10 in. for the first tier of floor beams, 2 x 8 in. for the second tier and 2 x 6 in. for the attic, all of spruce or yellow pine and with 2 x 6-in. rafters spaced 16 in. on centers. The girders supporting the first floor beams are to be 6 x 8-in. yellow pine, securely strapped and resting on 16 x 16-in. brick piers, bonded every fifth course with bond stones. All studs are to be 2 x 4-in. spruce or hemlock placed 16 in. on centers and doubled around all window and door openings.

The exterior framework is to be covered with pine sheathing boards dressed on the outside, laid diagonally and covered with building paper over which is to be placed the siding. The roofs are to be covered with shingles laid in regular courses and exposed 5½ in. to the weather.

The flooring is to be comb-grain tongued and grooved maple and blind nailed. The exterior cornice is to be formed of plain design of white pine or cypress and to return as shown on the elevations presented on the facing page.

The main entrance door is to be built up on a white pine core. All other doors are also to be of the built-up type and to be panelled, all being finished to match the trim.

PLASTERING AND INTERIOR TRIM

The various rooms are to be plastered two-coat work with a hard white finish or a sand finish for the living room, dining room and main hall according to preference of the owner.

The interior finish is plain throughout, the hall stairs to be finished with plain post and balustrade and the general trim of the various rooms to be of plain pattern and design with an artificial beam ceiling for the living room.

The plumbing fixtures are to be set, as shown on the plans and laundry tubs in the cellar. All fixtures are to be properly connected to the main soil pipe and vented.

The bath room is to have a floor of white tile laid on a bed of cement and cinder fill constructed between the floor beams.

The house is to be wired throughout for electrical

service and piped for gas, the fixtures to be of the combination type or they may be provided for either system should the local accommodations be limited.

The heating is to be by means of a hot-air furnace located in the cellar. There are to be registers in every room except the kitchen, also a register in the hall; an intake box is to be provided as well as all necessary appurtenances and appliances for a complete heating plant with ample capacity to heat the room farthest away from the source of heat to 70 deg. when it is zero weather outside.

The siding is to have three coats of paint and of a color to be selected by the owner. The roof shingles are to be dipped in stain before being laid and then given a brush coat after they are in place on the roof.

The interior trim is to be stained and the floors shellaced and varnished.

The hardware is to be of modest design and all necessary window catches, door locks, etc., are to be provided.

LAYOUT OF THE ROOMS

An examination of the floor plans shows the living room with its mantel of plain tapestry brick to be one of the noticeable features of the interior arrangement. The living room extends the full depth of the house and is lighted by triple windows front and rear with two windows in the end gable. A central hall extends entirely through the building and from it rises the main flight of stairs leading to the second story. Under the main flight are the stairs giving access to the cellar. Between the stairs and the kitchen is a commodious pantry which communicates directly with the dining room. The kitchen is shut off entirely from the dining room, an arrangement which tends to keep out the odors of cooking.

On the second floor are four sleeping rooms and bath room, all readily accessible from the stair hall which occupies the central portion of the building.

Each bedroom is provided with a clothes closet and opening from the hall is a linen closet. The stairs leading to the attic rise from a point just outside the bath room door.

CUBICAL CONTENT

The architect estimates the cubical content of the house to be 27,216 cu. ft. and he gives a unit price of 22 cents per cu. ft. He states that this figuring includes the contractors' customary profit, but the cost of the house will vary depending upon labor conditions and the locality in which it may be built.

It was designed by Architect Frank T. Fellner, 413 Caton Avenue, Brooklyn, N. Y., or care of the BUILDING AGE, 50 Union Square, New York City.

SOME WELL-ARRANGED FARM BUILDINGS

ADVANTAGES OF HOUSING STOCK IN ADJACENT BUILDINGS—HOLLOW TILE SILO AND MILKHOUSE

AN interesting example of a well-arranged farm, with modern buildings where all of the stock can be cared for without going out of doors, is to be found on the Adams Farm at Racine, Wis. Here is an instance where two large frame buildings are joined by a feed room, one accommodating a sanitary, light and well ventilated dairy barn on the ground floor, a horse barn on the first floor, and hay mow above, while the other has a ground floor cow barn and also a hay mow. A 150-ton silo has been built outside the feed room and between the two barn buildings, the location being such that the trucks can be loaded directly

concrete in the construction is commendable from the standpoint of cleanliness and economy.

The dairy barn has dimensions of 36 ft. wide and 48 ft. long, with an 8-ft. ceiling. A canopied entrance on the south side and stairs to the first floor at the front are provided, with half doors on the west leading to a yard. An abundance of natural light floods the barn through windows on all sides and the walls are plastered white. Running the length of the barn are twenty-one stanchions, in rows of ten and eleven, each compartment being equipped with a galvanized iron manger and watering bucket. The mangers in each row face one

MILK HOUSE, HORSE AND DAIRY BARN WITH SILO ON THE ADAMS FARM

from the silo on the inside and the mangers filled in each building without loss of time. A few feet to the south of the barns is a milkhouse and adjacent boiler and washroom, all of which present a group that is compact, of attractive appearance and embodying features in design and equipment that are interesting. The farm has capacity to take care of seven horses and thirty head of cattle, stanchions being provided for twenty-one milkers. The hay mows will hold a total of 100 tons of hay, the mow over the combination barn 40 tons, and that over the cow barn 60 tons. All buildings have an east frontage, and the use of hollow tile and

another and the alley is 6 ft. wide, so that the filling of mangers can be accomplished without loss of time. The barn is ventilated by rectangular ducts on the north and south walls, which are continued up through the horse barn and hay mow, connecting to a 30-in. ventilator on the roof. A litter carrier runs around three sides of the building, a branch to the boom in the yard being run through one of the half doors. The carrier is also continued through the feed room and cow barn, as shown on the accompanying floor plan.

The feed room measures 20 x 24 ft., sliding doors separating this section from the dairy and cow

barns. The silo is situated on the east and the room is plenty large enough to accommodate a feed machine and two large trucks. A 12 x 12-ft. engine room is west of the feed room, with door between.

The cow barn is 38 ft. wide and 42 ft. long, and houses a large bull pen, calves' pen and three box stalls, all conveniently arranged. A wide alley allows the feed truck to fill the mangers without trouble, each compartment being provided with mangers. Windows are installed on all sides of the barn and doors on the west side to the yard.

The horse barn is 9 ft. high and occupies the same floor area as the dairy barn, and on the east

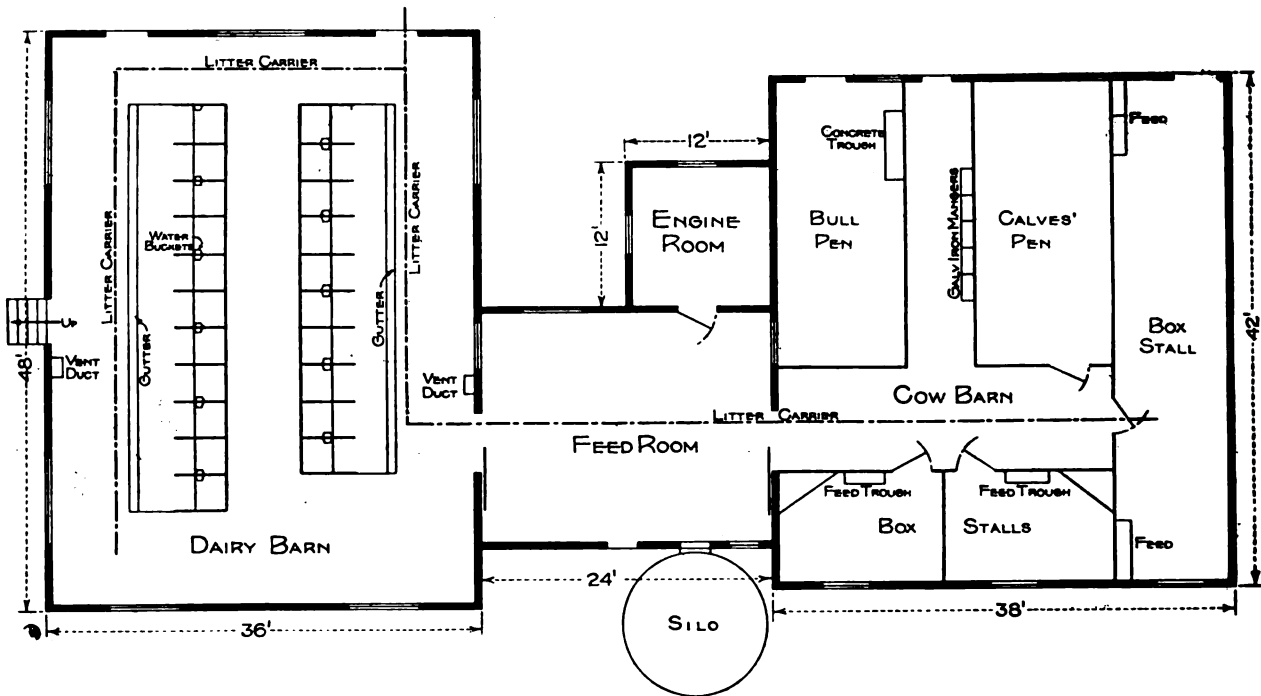

the manger. On the opposite side are five single stalls, 5 x 12 ft., with a feed alley conveniently run on the manger side. A watering tank and feed bins are provided at points shown on the accompanying plan. To the right of the entrance is a

Showing Stanchions in the Dairy Barn

Plan of Horse Barn—Scale 1/16 In. to the Foot

Plan of Dairy Barn and Silo, Showing General Arrangement—Scale 1/16 In. to the Foot

side is a sliding door, 10 ft. wide, at the top of a graded embankment. To the left of the entrance is a work bench running to the south wall, a space 12 x 20 ft. being utilized to accommodate wagons. Hooks are provided on the walls and posts to hang harness. On the south side of the building are two 12 x 12-ft. box stalls, each having a window over

stairway to the hay mow, a feed chute being built near the top of the stairs.

The hay mow is roomy, and a Strickler hay carrier, complete with forks and sling, is installed. At the east end of the mow is a hay door at the floor line and a larger door above, the latter being flanked on either side by a large window. A win-

dow near the ridge at the west end of the mow assists in lighting this section, the hip roof being 8 ft. high above the walls.

The milk house has dimensions of 12 ft. wide, 18 ft. long and 8 ft. high, divided into two sections. The east half houses the mechanical equipment, consisting of a Perry air pressure water system, the tank, pump and motor being arranged as shown on the accompanying floor plan. On the north side of this section is also a small tank, a milker pump and a lavatory in the corner. A concrete watering tank, milk cooler and cream separator are installed in the rear half of the building. The tank has outside dimensions of 5 ft. 8 in. long, 26 in. high and 40 in. wide, the walls being 4 in. thick. An 18 x 18-in. trap door over this room reveals an

faces are glazed and will not absorb moisture, an important feature that will appeal to the farmer who demands dry buildings. The insulating properties of the air spaces in the tile prevent dampness penetrating the walls and they keep the building cooler in summer and warmer in winter. Owing to their lightness, the tile are easy to handle, comparatively inexpensive to lay and permit speedy construction. The satisfaction and increased efficiency secured from neat, dry and warm buildings make this form of construction particularly desirable on the farm. All hollow tile used is "Natco," made by the National Fire Proofing Co., Pittsburgh, Pa.

In the construction of the milkhouse and boiler and washroom 8 x 8 x 16-in. tile was used, forming

REAR VIEW OF HORSE BARN WITH DAIRY BARN AT THE LEFT AND HOLLOW-TILE MILK HOUSE AT THE RIGHT

attic, the building being ventilated by two galvanized iron pipes installed at the ridge. Each section is lighted by three 18 x 24-in. windows on as many sides, with doors as shown.

The boiler and washroom is practically a duplicate of the milkhouse, measuring 12 x 20 ft. At the time of writing the building has yet to be completed so far as interior finish is concerned.

Hollow tile has been used extensively on this farm in the construction work and is an indication of its growing popularity for the building of rural structures. It is safe to say that the initial cost is the last cost, for hollow tile is durable and insures protection against the ravages of wind, fire, water and vermin. The rich brown surfaces present a pleasing contrast with the layers of mortar, making an attractive appearance and eliminating the necessity of frequent painting or other maintenance expense. Both exterior and interior sur-

faces are glazed and will not absorb moisture, an important feature that will appeal to the farmer who demands dry buildings. The insulating properties of the air spaces in the tile prevent dampness penetrating the walls and they keep the building cooler in summer and warmer in winter. Owing to their lightness, the tile are easy to handle, comparatively inexpensive to lay and permit speedy construction. The satisfaction and increased efficiency secured from neat, dry and warm buildings make this form of construction particularly desirable on the farm. All hollow tile used is "Natco," made by the National Fire Proofing Co., Pittsburgh, Pa.

In constructing the horse and dairy barn, 24-in. concrete footings were provided and 8-in. foundation walls of vitrified tile with double air space built of 8 x 8 x 16-in. tile. The floor of the dairy barn is 6 in. thick and rests on a 4-in. bed of cinders, the finished floor being pitched from the center toward the sides of the building. A double row of steel posts line the center of the dairy barn and are placed back of the mangers in every third stall, securely anchored in the concrete floor and capped

with concrete beneath the beams. The stall posts, partitions and top rails are built of steel tubing, the stanchions being connected both top and bottom. The mangers and watering buckets are of galvanized iron. All barn equipment is of a type made by the James Mfg. Co., Ft. Atkinson, Wis. Each stall is 3 ft. wide and 3 ft. 6 in. long, and back of the stalls is a long concrete gutter, 16 in. wide and 6 in. deep.

The floor of the horse barn is of reinforced concrete, 6 in. thick. The framing of the building is

Hollow Tile Milk House. Boiler and Wash Rooms

View of Litter Carrier, Showing Boom, Guy Wires, Swinging Crane, Etc.

simple and typical of Middle Western practice. On the foundation walls are 2 x 6-in. plates, while the studs, rafters and braces are of the same size material. Girders are 8 x 8's and floor joists 2 x 8 in., and the walls covered with 6-in. drop siding. Braces and collar beams are 2 x 4's. The roofs of all buildings are covered with best white cedar shingles, exposed 5 in. to the weather.

The silo is 14 ft. in diameter and 38 ft. high. In the building of it regular "Natco" 12 x 12 x 6-in. silo tile were used. All exterior woodwork received two coats of paint.

The carpentry work was done by Newton Brown and the masonry work was executed by James Due, both of Racine, Wis.

Fence posts in Argentina are made of quelbracho wood, which is exceedingly hard. It is said that the posts last forty years.

A FACTORY BUILT ON CONCRETE PILES

A factory has recently been completed in Montreal, Canada, which has its foundation built on about 400 Raymond concrete piles. This construction was necessary owing to the peculiar nature of the soil. In addition, the ground is underdrained, so that four catch-basins, one at each end and one at each side, are provided.

The structure is in two sections, one of four stories and basement, the other one story and basement. Heavy mill construction, designed by W. B. McLean to fit the requirements of the case, is used.

To minimize fire losses, and insure the safety of the employees, each floor is entirely separate, and can only be reached from a fireproof stair tower protected by fire doors at every floor. In this way,

Plan of Milk House—Scale $\frac{1}{4}$ In. to the Foot

a fire in any of the departments would be confined to that room. The stairway is of concrete.

The elevator runs in a heavy brick tower, also shut off by fire doors at each floor. This tower is extended above the roof to carry the sprinkler tank.

The building is of plastic brick, with windows of steel. The floors are supported by beams of Douglas fir, with Duplex hangers and post caps. The roof was built to Barrett specifications. The building also has an efficient sprinkler system.

The volume of building operations in the District of Columbia for the fiscal year ending June 30, 1916, was the greatest since 1912. The grand total for all operations, according to the annual report of Building Inspector Morris Hacker, was \$13,495,535, which is an increase over the previous fiscal year of \$4,895,603.

A 1½-TON "KELLY" MOTOR TRUCK OWNED BY T. A. GRAHAM OF SPRINGFIELD, OHIO—LOADING A CONCRETE MIXER

MOTOR TRUCKS AID BUSINESS EFFICIENCY

CONTRACTORS AND BUILDERS FIND THEM SUPERIOR
TO HORSES AND WAGONS AND ADVOCATE THEIR USE

IT has been estimated by an expert in the motor truck industry that possibly not more than one per cent of the contractors and builders in the field of moderate cost construction are using motor trucks, and his figures do not include trucks used by building material houses or concerns undertaking contracts for such work as office buildings, industrial plants and structures of that character. If

trucks to advantage, and further evidence is obtainable that many contractors in Central Western and Eastern States find trucks indispensable in the successful conduct of their business. The very fact that they are being used is sufficient evidence of the economical worth and necessity of modern road transportation wherever they are needed.

The investigation conducted in the Middle West,

A "FEDERAL" MOTOR TRUCK USED BY A FIRM OF BUILDING CONTRACTORS AND PLUMBERS

his estimate is anywhere near true, then it is logical to believe that motor trucks are not required by the majority of these contractors or that they have not given serious consideration to the efficiency and economy of the power wagon as compared with the horse and wagon.

Investigation has shown, however, that in the State of Illinois there are many carpenters and builders, in large and small towns, using motor

which was naturally somewhat limited in its scope, showed the prevalence of an almost unanimous opinion that a light truck is an ideal one for general use. The majority of the men interviewed were using one-ton trucks, though some were of lighter or heavier capacity, but none exceeded two tons. Many had improvised trucks in the form of a substantial box securely held in place at the rear of a Ford roadster, and it was learned that small stuff can be carried on

such a car without fear of overloading the machine, and the cost of upkeep is extremely low. In a general way every man spoke enthusiastically of the efficiency of trucks over horses and wagons and considered them indispensable to their business. Since acquiring trucks many have increased the radius of their working territory without materially increasing their overhead expenses from the standpoint of delivery costs. Instances were cited to show that certain business could not be undertaken profitably were it not for the fact that a truck is maintained for hauling materials, equipment, and even men, when occasion required.

Practically every contractor is confronted with the problem of delivering something at some time or another, if not regularly, from the shop to the job. Where stocks of lumber, cement, etc., are kept in the shop or yard, the possession of a light truck is not only responsible for getting materials to the work at the right time, but, furthermore, the contractor is able to get around to the various jobs himself and keep in close touch with all operations. Many contractors and builders utilize trucks to take men from one job to another, especially in the larger cities, where wages are high and time a very important factor.

COMPETITION AND THE MOTOR TRUCK

The pressure of competition often compels a man to buy a motor truck. Others purchase them through force of necessity, for it is often costly to have to depend on teams furnished by another party, and they prefer to invest in a motor truck rather than have to wait someone else's convenience. Supplies can be transported promptly and economically from the freight cars to the job, and the same can be said of handling concrete mixers, saw rigs, etc. This is especially true where country work is done, though some territories have such bad roads that motor trucks are out of the question so far as the contractor is concerned.

The contractor and builder contemplating the purchase of a motor truck is confronted with the problem of just which one to buy. This question involves the radius to be covered, the nature of the average load, and the condition of the roads in his immediate and surrounding territory.

The man who will chart daily the number of deliveries his wagon makes, ascertaining the weight of each load and the number of miles covered, is best fitted to select a truck of the capacity which will operate most economically in his service. When a single truck is operated, reports from the driver should be kept showing the daily expense. Such a chart will readily tell the owner when waste is occurring or when his machine is not receiving the right amount of care.

WAGONS VS. MOTOR TRUCKS

The extent to which the automobile and motor truck are displacing the horse-drawn vehicle is indicated by a report of the census of the carriage and wagon industry, just issued by Director Sam L. Rogers of the Bureau of the Census of Washington, showing that the number of carriages and wagons manufactured in 1914 was 397,569 less than

in 1909, a decrease of 25.1 per cent. Likewise the value of the total number of these classes of vehicles decreased \$21,754,002, or 23.1 per cent.

To those who have accepted horse transportation, its cost and limitations, for so long a time, it is difficult for them to see the many advantages of the power wagon without first being shown figures substantiating the claims of the truck.

TREATMENT OF THE TRUCK

The owner of a horse and wagon has been accustomed to let his team run until the wagon broke down or the horse became sick. If he is inclined to treat his truck the same way, such treatment will prove expensive in the long run. Overloading a truck should be avoided at all times, as additional weight above the rated capacity strains the engine, and bad roads will affect the tires and general condition of the machine. The main reason that overloading is permitted at all is because the cost of it is not immediately apparent. It must be borne in mind that this cost must be paid sooner or later.

In many instances men are justified in criticising the amount of money that must be spent for investment and upkeep, because they feel that the amount of business they transact annually does not warrant the purchase of a modern light truck. It is not the purpose of this article to say that every carpenter and builder should buy a truck, but this is true, and the following evidence will prove the contention, that any contractor using one or more teams can do more work in a wider territory at less expense with a light auto truck.

SECRET OF TRUCK ECONOMY

The secret of making a truck save money is in keeping it busy all the time and so arranging the hauls that it will be necessary to make the fewest number of empty trips. It is absolutely necessary that the machine be kept in good condition. Like all other machines, when one part of a motor truck is kept in service after it is badly worn, other parts begin to wear more rapidly than they should, and general breakdown soon results. A good truck, properly used, should pay for itself inside of four years and still show a very fair profit.

The advertising value of the truck should not be overlooked. It is an acknowledged sign of modern equipment and progressiveness, and as such invites confidence. A man operating a 1000-lb. truck said:

It costs one-third for gasoline compared with the cost of feeding a horse.

It requires one-half the time to fill the gasoline tank, oiler, grease cups, oil all parts and occasional cleaning of spark plugs, compared with the time required to feed and clean a horse.

The distance covered by a horse and wagon and the speed which it makes are very limited. The distance we can cover with our truck is unlimited, and in the city we can travel 18 miles per hour.

A horse must be fed and watered whether working or not: a motor truck consumes only while in motion.

The owner of a 1½-ton Federal truck, made by the Federal Motor Truck Co., Detroit, Mich., who also operates horse teams, attached hub recorders to the machine and a wagon in order to better compare their earning capacity in his business. The wagon was loaded and unloaded in exactly the same manner as the truck, but the machine covered 3.66 miles to every one for the team. The truck hauled

each load twice as far, yet it made twice the number of deliveries. The running and stopped time made by the team figured out at 1.64 miles, while for the

The "Chicago" Motor Truck of M. H. McLean, a Chicago Carpenter and Builder

truck it was 7.15. This greatly increased earning capacity cost the operator \$1.28 per day more.

The owner of a one-ton Little Giant motor truck, made by the Chicago Pneumatic Tool Co., Chicago, Ill., who does a contracting business, said that his primary reason for buying a truck was to get a vehicle that would handle light orders quickly. He finds it especially valuable for country work, and states that without the truck it would be impossible to go out of town and make money. If the men had to be driven in a horse and wagon to the job, the time lost going and returning would eat up all the profit, more especially where the workmen would have to be boarded. At the present time he handles jobs within a radius of 10 miles. In many instances the truck leaves town at 6.30 a. m. and has the gang on the job ready for work at 7 o'clock. He then brings the truck back to town for local use and goes back to the job later in the day to get the men back to town by 5 o'clock. No time is lost, and the men are all kept good natured because they get home as soon as they would if they were working in town. As to the cost of operation, mileage considered, the truck is a good deal cheaper than horse and wagon delivery, and from the standpoint of service the owner thinks that there is absolutely no comparison, the truck being considered indispensable.

The J. L. Simmons Co., contractors and builders of Chicago, have used a Velie truck, made by the Velie Motor Truck Co., Moline, Ill., with much success for many years. In connection with its work on the Moline, Ill., high school building, the entire hauling of materials from freight cars to the building was done with the truck and accomplished what it would require five teams to do. This distance covered was nine blocks, two of which were up a

20 per cent grade. In handling the material the company used six skips, each holding about 1000 brick, and while two of the skips were being loaded at the cars, two were sent up to the job on the truck, and on arrival at the building were lifted off with a boom derrick and the two empties replaced on the truck. By this method the truck did not have to wait to be loaded or unloaded, except as the derricks at the cars or the building lifted the skips off or onto the truck. This procedure enabled the company to keep the cost of placing the brick from the cars to the building at less than \$1 per thousand, and all other materials relative as low. The truck operated almost continuously through a 9-hour day and used less than 8 gal. of gasoline.

Louis A. Riffle, a Chicago carpenter-contractor, does not believe a horse and wagon could do the same amount of work as his one-ton Atlas truck, and the former used to cost him \$25 per month as compared with \$17 per month for the latter. Mr. Riffle states that he now does business in a wider territory since acquiring the truck, and recom-

mends their use to carpenters and builders as a means of increasing business efficiency. He has used it for 18 months with satisfaction, and his loads average from 1000 to 2000 lb.

John Denman, a Chicago carpenter-contractor, finds very useful an improvised auto truck consisting of a small body at the back of a Ford roadster. Its average cost is \$4 per month, and occasions very little trouble.

Mr. Denman does considerable jobbing work, storm doors and sash are made to order, and business is

The One-Ton "Sterling" Motor Truck of A. Haugen, a Chicago Builder and Contractor

The "Reo" Motor Truck of the David Henry Building Co. of Paterson and Newark, N. J.

done in screens and weather stripping. It is an easy matter to carry such materials to and from a home and the trips can be made very quickly.

DECEMBER, 1916

INDEX FOR 1916 VOLUME

Those of our readers who contemplate binding their copies of the BUILDING AGE for 1916 will be interested to know that the index for the current volume is now ready for distribution. Anyone desirous of securing a copy of the index can do so on application to this office.

THE CORRESPONDENCE DEPARTMENT

We are sure that the majority of carpenters and builders among our readers will unhesitatingly agree that the Correspondence Department is one of the most important sections of the paper, constituting as it does an excellent medium for the interchange of ideas between those practically engaged in the building business. It is always interesting for members of the trade in one part of the country to learn of the methods of doing work which prevail in other sections remote to those in which they reside, and by discussion of those methods bring out a fund of information which cannot fail to be valuable to all concerned. The aim of the Correspondence Department is to promote this interchange of ideas and to stimulate greater interest on the part of the younger element in the trade. At the same time, there is always the desire to make the department still more valuable to those for whom it is intended,

but this can only be accomplished by the active co-operation of our practical readers. Those who have so generously benefited from the information obtained from volumes of the paper in the past should feel a desire to reciprocate by contributing from their personal records of experience some of the hints and suggestions which they have found valuable in their business. Every progressive carpenter and builder in the country has well-defined ideas for doing all kinds of work which he may be called upon to execute, and short descriptions of unusual or peculiar jobs cannot fail to prove highly interesting to those who perhaps have had less practical experience.

CONTRIBUTIONS INVITED

We want the younger members of the trade to ask such questions as will draw out expressions of opinion from the veterans in the business, and thus induce them to comment upon some of the many topics which constantly come up for discussion; to point out to the less experienced craftsmen wherein they can do better work or make more rapid progress by adopting methods which experience in the past has demonstrated to be in every way satisfactory. The older hands can reply to the questions of the younger members, and in this way develop an active interest in the welfare of the paper as well as in promoting the material interests of their brother chips. In this way, too, they will be rendering a good service to their fellow craftsmen in return for the benefits which they themselves derived through similar methods in the past.

We want every carpenter and builder to take advantage of the long winter evenings now at hand and each month send a few lines to the Editor dealing with some phase of building work as outlined in a general way above. His contributions will be carefully edited and published under initials only, or with his full name should he so desire. Pencil sketches will be carefully worked up to standard and the matter put into shape for publication so that no one need hesitate on these points. It is obvious that the more letters we can publish each month from our practical readers the greater will be the value of the Correspondence Department to all concerned. We hope that everyone will feel free to respond and thus do his share towards making the paper still more valuable to those in whose interests it is published.

One of the things that makes pine popular and comparatively inexpensive in mill work is that it is easier to work and easier to nail up than hardwood, consequently it finds greater favor with both machine men and carpenters.

CORRESPONDENCE

A Department Where Those Interested Can Discuss
Trade Topics—Every Reader is Invited to Participate

ENCLOSING A FRONT PORCH

From John Wavrek, Jr.—The time of year is at hand when our thoughts naturally turn, and with some dread when we consider the price of coal, to the approach of winter. Naturally we begin to think of ways and means as to the manner in which we can most effectually keep the bitter cold out of our houses. One method of doing this very satisfactorily is by enclosing the porch or veranda as some term it with sash and the scheme shown in

The top rail of the lower sash is rabbetted to fit the bottom rail of the pivoted transom. This makes a rabbetted opening which can be utilized to receive fly screens in summer, the sash being removed but the transoms left in place. It can readily be seen that this arrangement is very handy, allowing the interchanging of sash with fly screens.

It is not strictly necessary to use $1\frac{3}{4}$ -in. lumber for an enclosed porch as the same effect can be produced by using $1\frac{3}{8}$ -in. stock. The $1\frac{3}{4}$ -in. lumber

Fig. 6—
Section
on Line
B-B

the accompanying sketches will be found to go far in accomplishing this end.

The frame work is made of cypress $1\frac{3}{4}$ in. thick. The head piece is $1\frac{3}{4} \times 3$ in. and rabbetted $\frac{1}{2}$ to $\frac{7}{8}$ in. on the inside. The end pieces are 4 in. wide, rabbetted in the upper part for pivoted transoms and in the lower part for sash, which may be hinged if desired. This, however, is not necessary because the pivoted transoms will provide all the ventilation that may be required. The mullions are 4 in. wide outside and are also rabbetted in the same manner as the end pieces. The sill is $2\frac{1}{2} \times 4\frac{1}{2}$ in. and is also rabbetted on the inside.

will, however, make a much stronger and more rigid construction and is designed for the better class of houses. The glass arrangement of the sash can, of course, be made to suit the owner. Most people prefer small lights instead of large ones, as shown. This, however, does not affect the construction in general.

It will be noticed that the columns against which the uprights have to be fitted are round and there are numerous molds over which the pieces have to be fitted. This, of course, requires great care so as to make a tight job, but by hollowing out the pieces a tight joint may be obtained by inserting

oakum before putting the stiles in place. It is a good plan to make a pattern of paste board which neatly fits over all the members and then have the pieces sawed out by a careful band sawyer. Referring to the sketches Fig. 1 represents the plan of the porch and also the arrangement of the sash. Figs. 2 and 3 show the front and end elevations respectively, while Fig. 4 is a vertical section taken on the line A-A of the elevation. Figs. 5 and 6 show details of construction to a somewhat larger scale than the elevations.

A porch thus enclosed will be found to greatly enhance the appearance of the house and at the same time raises the value of the property to an appreciable extent. I cheerfully recommend the treating of front porches in this manner as the owner will surely not regret spending the money, as he will be compensated in more ways than one.

OIL-MIXED CONCRETE

From Contractor, New York.—In answering the questions raised in the November issue of the paper by "O. M. R.," West Haven, Conn., I would say that I made several vessels with 5 per cent and 10 per cent of Maltha mixed with the cement and sand before the stones were added or when omitted. These vessels have been used continuously since before the article in question was written. The vessels do not become saturated nor will anything placed under them become moist, while those having no oil in the mixture saturate in a few minutes. For ordinary work from 5 per cent to 7 per cent will serve.

The mortar must be quite dry before the oil is added, as 10 quarts to the barrel makes it very mushy. A person need not worry about letting it stand a few hours before putting in place. I remixed after 30 hours' setting. It clings to a wire as firmly as it does without oil. Maltha is a Standard Oil Company product and is all ready to use. I did nothing with the samples sent me except to experiment with them. Water can be forced through iron, and of course it can be forced through any sort of concrete. For cement blocks, stucco inside and out, and for stables and poultry houses Maltha should be used, as the added expense is negligible.

APPLYING SCAGLIOLA TO CEMENT

From Ernest McCullough, Chicago, Ill.—Answering the query of "E. M. K.," East Dourington, Pa., I would say that superior scagliola, known as Marezzo, is made in slabs and put in place like marble or any released ashlar. Make a very thin paste, called "slip," of Keene's cement colored to the tint required for the veinings of the imitation marble. There will be usually several colors.

In these dishes of "slip" lay threads of suitable fiber and when they are coated lay them on sheets of glass to form the markings and veinings. Now reduce the thickness of the slip and the color of it

to the color to be used for the body and pour it over the fibers. Then carefully remove the threads and the veining colors will remain. Sprinkle over the mass some dry cement to absorb the superfluous moisture.

A canvas backing is then laid on for strength and a coating of cement mortar is added to bring it to the desired thickness. When dry the slab is removed from the glass pallet and polished. The polishing is done with felt dipped in linseed oil. The felt should be made into a regular wood backed rubber for convenience in handling.

To apply scagliola to a wall surface first put on a coat of hard plaster. This plaster can be preferably of one part Portland cement to three parts of clean graded sand. For convenience in applying there can be added dry to the cement before mixing one pound of best quality hydrated lime for every twenty pounds of cement. Instead of the cement mortar coat we can use a coat of hard or patent plaster containing a fiber or hair binder.

The first coat must be thoroughly set and hard before the second coat is applied. The second coat consists of Keene's cement or plaster of Paris properly colored to imitate the marble and the veining can be produced by laying in the surface threads loaded with a thicker "slip" of the desired color. Ability to imitate marble comes with practice.

Coloring may be by means of dyes or by the use of reducible metal salts. The dyes come in the form of powders and may be obtained from all dealers in plasterers' materials and from chemical supply houses. The dry powder is mixed with the cement and the resulting color is not always uniform and it is not very lasting.

To use the metallic salts, which any chemical supply house can furnish, dissolve the salts in the mixing water. Mix a small amount of formaldehyde and an alkali with the plaster and then add the colored mixing water. The result will be a uniformly colored plaster of a most lasting kind. If parts chip off the color is not injured, as when paints are used. It is not necessary to use formaldehyde if sulphurous acid or peroxide of hydrogen can be readily obtained. The alkali, however, must be used.

Sometimes the veining is produced on the surface by cutting lines with the point of a knife blade and filling the scratches with coloring matter applied with a limning brush.

If the Keene's cement or plaster of Paris set too rapidly mix with 4 per cent by weight of either powdered marshmallow root, or dextrin, or gum arabic, or glue. The quantities mentioned will delay the setting about an hour. Double the quantity will cause the setting to be delayed 2 to 3 hours and makes the plaster very readily worked. It toughens it very greatly so it is readily carved and polished when set. One ounce of citric acid added to 100 lb. of plaster of Paris will delay the setting 2 to 3 hr. but does not increase the toughness.

The polishing of scagliola is done by first smoothing off the surface, if it is not cast on glass, by rubbing it with pumice stone, then with Tripoli followed with pulverized charcoal and finally by a

felt rubber dipped in linseed oil. Sometimes plates or slabs of *Marezzo* require polishing with the pumice stone, Tripoli and charcoal.

If the mixing and veining and fine work connected with these operations are too complicated there can be applied on top of the hard coat a second coat of hard Keene's cement or plaster of Paris mixed with glue water. After it has set perfectly it should be polished with the pumice stone, the Tripoli and the powdered charcoal but not with the felt rubber soaked in linseed oil. When the polishing is completed rub the surface clean with a rag or sponge dipped in benzine.

Use water colors with a little ox-gall or Aquoline added, and paint the surface to imitate marble. A surface painted with water colors cannot be polished. It must be varnished to present a smooth appearance, and if struck hard the surface will chip and reveal the fact that it is painted.

The foregoing sounds complicated, but so will the description of many of the common doings of skilled workmen sound complicated to amateurs. A competent plasterer following the hints here given should develop into an artist on scagliola work after considerable practice. Some men get the knack on the first job while others have to spoil many jobs before they attain proficiency.

VERANDA, PORTICO AND PORCH

From C. W. H., Pretoria, Ga.—Will some of the practical readers or the editor tell me the difference between veranda, portico and porch? In what respect do they differ in construction? Is it the size, form or locality that gives rise to the different names? In some sections I find the people calling everything in the shape of a covered entrance to a building a porch and in others a veranda. I hope some one will explain the difference and settle the matter.

Note.—The terms mentioned by our correspondent are often employed interchangeably in many sections of the country to designate the covered entrance to a building, although strictly speaking there is a difference in the form and construction by which each may be distinguished. Locality also has something to do with the use of the terms by which these portions of a dwelling are often called, "veranda" or "piazza" being common in the New England states and some other parts of the North, while in the West and certain sections of the South "porch" is the word generally employed. In some parts of the extreme South and South-west "gallery" is the designating term, but in every section it seems to be more or less a matter of individual taste.

Webster's Dictionary defines "porch" as "a covered and inclosed entrance to a building, whether taken from the interior and forming a sort of vestibule within the main wall, or projecting without and having a separate roof." The same authority gives the definition of "portico" as "a colonnade at the entrance of a building."

In the one case, therefore, it is an inclosed en-

trance which may be just within the main wall or projecting outside, having a separate roof, and in the other it is a covered entrance having a row of columns placed at regular intervals along its front. The word "veranda" is defined by Webster as meaning "an open roofed gallery or portico adjoining a dwelling house and forming an out-of-door sitting room." A more popular idea of the meaning of the term is a covered approach to a dwelling which partially, at least, extends along two or more of its sides, while if it extends only across the front or a portion of the front it is either a porch or a portico, according to the fancy of the individual.

Our correspondent will see from the above that while porch, portico and veranda differ somewhat in construction and form, their uses are similar, and probably for this reason the terms are often interchangeably employed. The subject raised by our correspondent is a good one for discussion and we hope the readers in different sections of the country will write us concerning the local use of the terms named.

CONSTRUCTING A DRAWING BOARD

From O. B. M., New York City.—The enclosed original sketch of a drawing board may prove of interest to some of the readers of the paper, more especially in view of the discussion which occurred in these columns on the subject a short time ago. The sketch shows one of a pair of

CONSTRUCTING A DRAWING BOARD

wooden horses each 37 in. high, but with legs 33 in. long. The legs are made of $\frac{7}{8}$ -in. material $2\frac{1}{2}$ in. in width. The support for the adjusting bar is a piece of 3 x 2-in. stuff mortised at the ends as shown, while the adjusting bar in cross section measures 2 x $2\frac{1}{2}$ in. The pieces used for raising and lowering the adjusting bar are of oak, each measuring $2\frac{1}{2}$ x 1 in. in cross section.

The drawing board is of $\frac{3}{4}$ -in. material and measures 32 x 42 in. in area. It is stiffened as shown in the sketch by means of oak battens

measuring $1\frac{1}{2} \times 2\frac{1}{2}$ in. The board itself is of white pine and all joints are glued.

THE NEW STYLE HEADINGS IN THE BUILDING AGE

From Hee H. See, Sacramento, Cal.—I have just bought a new pair of shoes, which is an experience familiar to all of us and not to be enlarged upon; I merely wish to mention the fact that I got into quite a heated argument with the storekeeper because he could not supply me with the same style of shoe I was wearing and which I had bought at his place only a few months before. His best excuse was that he had to keep his stock up-to-date and that particular shoe had gone out of style.

It is probable I would have forgotten all about this if I had not that same evening picked up the BUILDING AGE and noticed the paragraph announcing the change of address and mentioning typographical changes, made and to be made in the paper. My thoughts at once returned to the storekeeper who thought I ought to change the shape of my feet every three or four months in order that he might keep his stock up-to-date, and I began to consider how much money is spent every year, in every line of business, merely for the sake of keeping up-to-date.

I suppose there was a good reason for changing the headings of the articles in the BUILDING AGE, and no doubt someone gave his attention to the matter for a considerable period. Personally, however, I prefer the headings as they were in the September and previous issues.

It would be interesting to know what percentage of the readers noticed that there had been any change, and of this percentage how many of them thought it a change for the better.

I imagine that most of us read the paper because of the authentic knowledge we find in its columns, and if that is as good in the future as it has been in years past, not many of us are going to worry about the headings or make-up.

That is the way I feel about it now, but no doubt if the paper ever did come out in its shirt-sleeves or in any other slipshod style of dress, I'd be one of the first to register a "kick."

REMOVING CONCRETE COVERING OF A WOODEN FLOOR

From H. R. T., Peoria, Ill.—Supplementing the statement of the difficulty which I experienced with the "sweating" of a concrete covered floor and which appeared on page 56 of the November issue of the BUILDING AGE, I am sending some particulars of the means which we employed to remove the concrete covering. It will be recalled that the cement floors were laid over a rough flooring and it caused me a great deal of trouble from the moisture which collected on them.

Having secured permission of the owner to tear up these floors and replace them with oak floors,

the first thing we did was to obtain several broken automobile springs. After chipping out a hole we were able to drive the springs under the cement and by tapping upon it we could spring the concrete just enough to crack it so that we could lift it and the pieces would not fly about and damage the mop board and walls. It was of course necessary to secure springs with considerable bow in them. We found that the springs did such little damage to the rough flooring that we laid the oak floor on it, while in the case of the rooms where we were obliged to use picks and chisels it was necessary to lay an entire new subflooring.

I might add that where the springs were used in taking out old floors we did the work and laid the new hardwood floors without asking the tenants to vacate the premises.

WEDGING A HAUNCHED TENON

From E. G. E., Mt. Vernon, New York.—The query presented by "W. H. C." of Peoria is an interesting one, and the following solution of this problem will, I think, meet the requirements of the case.

By finding how the wedges affect the tenon, we can deduce the better method. Let us take his Fig. 2 first. When the upper wedge is driven in it forces the wood above it up against the mortise and the wood below the wedge is forced down against the mortise. The lower wedge acts in the same way, adding its thrust to the upper wedge and down to the mortise. The wood displaced by the wedges will so swell the tenon that the friction of the tenon against the mortise will hold the joint secure. But there is great danger of the tenon splitting sooner or later and therefore the joint, as a whole, is weak. Any carpenter knows how he can split his wood by a wedge and he can see that this is what he is doing to the tenon when constructing the joint as shown in Fig. 2.

Now let us see how his Fig. 1 works. The upper wedge presses up against the mortise and down against the tenon, perhaps crushing the wood. The lower wedge, as it is driven in, pushes the tenon up and also forces itself against the mortise. Thus the joint is held secure by the friction of the mortise and tenon against the wedges. There being four friction surfaces instead of the two shown in Fig. 2, there is more tendency for the tenon to slip, although it is amply secure. But it will be seen that there is no danger of splitting the tenon, as there is in Fig. 2.

A careful reading of this explanation will show that the friction between the mortise and tenon is greater in Fig. 2 than in Fig. 1, but the weakening of the tenon in Fig. 2 makes the joint an unsafe one, therefore Fig. 1 is the better joint.

A miniature "open-air" school is being built by students of the St. Paul (Minn.) Industrial School under the direction of the manual training teacher. A concrete foundation wall, cast iron columns to support the roof, and removable canvas walls contribute to form a realistic model.

ARRANGEMENT OF SLIDING GARAGE DOORS

THOSE OF THE SLIDING-FOLDING TYPE CONSIDERED AT THIS TIME—VARIOUS DETAILS

By E. J. G. PHILLIPS

THE private garage is one of the comparatively new buildings which has come into existence, and with its coming has brought new problems to be solved. Its style must be in keeping with the automobile to be housed and its architecture should harmonize with the residence to which it belongs. Plenty of room for the car and a liberal allowance of space to work around it must all be provided without making the building unduly large or occupying more than the frequently limited amount of ground space. The doors must occupy the greater part of one side of the building and a place must be found for them when the doorway is to be opened. Without doubt, the doors should be inside of the building, but very little space inside of the garage can be appropriated for use in the movement of the doors. It is the problems arising in connection with the door question that will be dealt with in the following paragraphs. Several

noticed from the plans, the doors fit flush in the door frame and the joints between the doors are rabbetted so that a very tight job is the result.

All the doors should be made the same width over all and the rabbets should be arranged exactly as shown on the plans. A door stop is fitted around the sides and top of the opening.

Locate the center of the hangers $2\frac{3}{4}$ in. from the edge of the door on four door openings, but for three, five or six door openings the hanger apron should be set flush with the edge of the door. The top of the hanger apron may be set in line with the top of the door on three or four door openings, but on five or six door openings, it should be set about $2\frac{1}{4}$ in. above the top of the door, as in Fig. 4. The end of the track over the hanger when the doors are closed is set close to the wall, but the outer end is supported at varying distances from the wall by adjustable track brackets, the distance from the

Fig. 1—Five Sliding Door Openings

Fig. 2—The Doors Shown Nearly Open

general types of doors designed especially for garages will be shown and the various applications will be described. Although this article refers chiefly to private garages, a number of the plans suggested are also suitable for public garages.

The colonial brick garage shown in Figs. 1 and 2 illustrates a comparatively new type of garage door, the general feature of which is the use of a number of narrow doors hinged together in two sections and folding toward the sides of the opening. The illustrations show an opening closed by five doors, but the idea is not limited to this number of doors. Three, four, five or six doors per opening will meet all requirements. These doors fold inside of the building, but being narrow, do not require a great deal of space in which to operate. The second door from the jamb is always supported and guided by a hanger sliding in a trolley track. This feature also gives positive control of the doors. As may be

wall depending upon the position in which the doors stand when open. The end and intermediate brackets are shown in Fig. 7, and attention should also be directed to the vertical adjustment by which the track can be carefully leveled so the hanger will rest in the track at all positions without unduly straining the hinge fastenings. The plans show the doors standing at different angles, depending upon the wall space adjoining the opening in the different plans. Any angle or position of the doors may be obtained by adjusting the outer end of the tracks away from or toward the wall. The doors are locked by top and bottom bolts, adjustable for varying heights of doors.

The plans and interior elevations, Figs. 3 to 6, show the necessary hardware for trimming three, four, five or six door openings. In the three door opening, Fig. 3, two doors are hinged together and fold toward the right. The third door is hinged

to the opposite jamb and is used as a passage or entrance door. This is particularly adapted to a small garage with an 8-ft. opening and no other entrance. Two doors fold toward each side in Fig. 4. The four door openings should only be used when there is another entrance, but the three, five or six door openings all have one passage or service door to be used in walking in or out, thus making it unnecessary to open a large door or a number of doors. The passage doors are locked with regular cylinder locks.

Three doors fold toward one side and two toward the other side in Fig. 5. This is similar to that used on the garage shown in Figs. 1 and 2. The center door in this case is the passage door. The door to which it is hinged is held rigidly in place by the top and bottom bolts, the floor guide and the hanger.

Fig. 7—Details of the End and Intermediate Brackets

Fig. 3—Inside Elevation of Three Doors Showing the Hardware

The use of the passage door is clearly shown in Fig. 1. In Fig. 6 three doors fold toward each side. The door to which the passage door locks in the center of the opening is held securely in place by the top and bottom bolt. This arrangement provides for openings as wide as 18 ft., which covers the range of ordinary requirements. The cross-sections at the bottom of Fig. 4 show the hanger attached to a cased opening and also to an opening which is faced flush with the inside walls.

As noted previously, these illustrations show the heights at which the hangers are located on the doors for different combinations. The minimum headroom is 6 in. for three or four doors and 8 1/4 in. for five or six doors. The doors should not exceed 3 ft. in width. When three doors fold to one side, as in the five or six door openings, the tie rod or brace will assist in supporting the doors and keep them from sagging and dragging on the floor. (To be continued)

THE HOLDING POWER OF NAILS

The holding power of nails in wood, and especially in hard woods, has not received a great deal of attention. The nailing of soft woods, such as pine, is supposed to come to people like walking, with all the proportions of length and thickness of nail for the size of wood to be put together. The

Fig. 4—Inside Elevation of Four Doors with Details of Hanger Arrangement

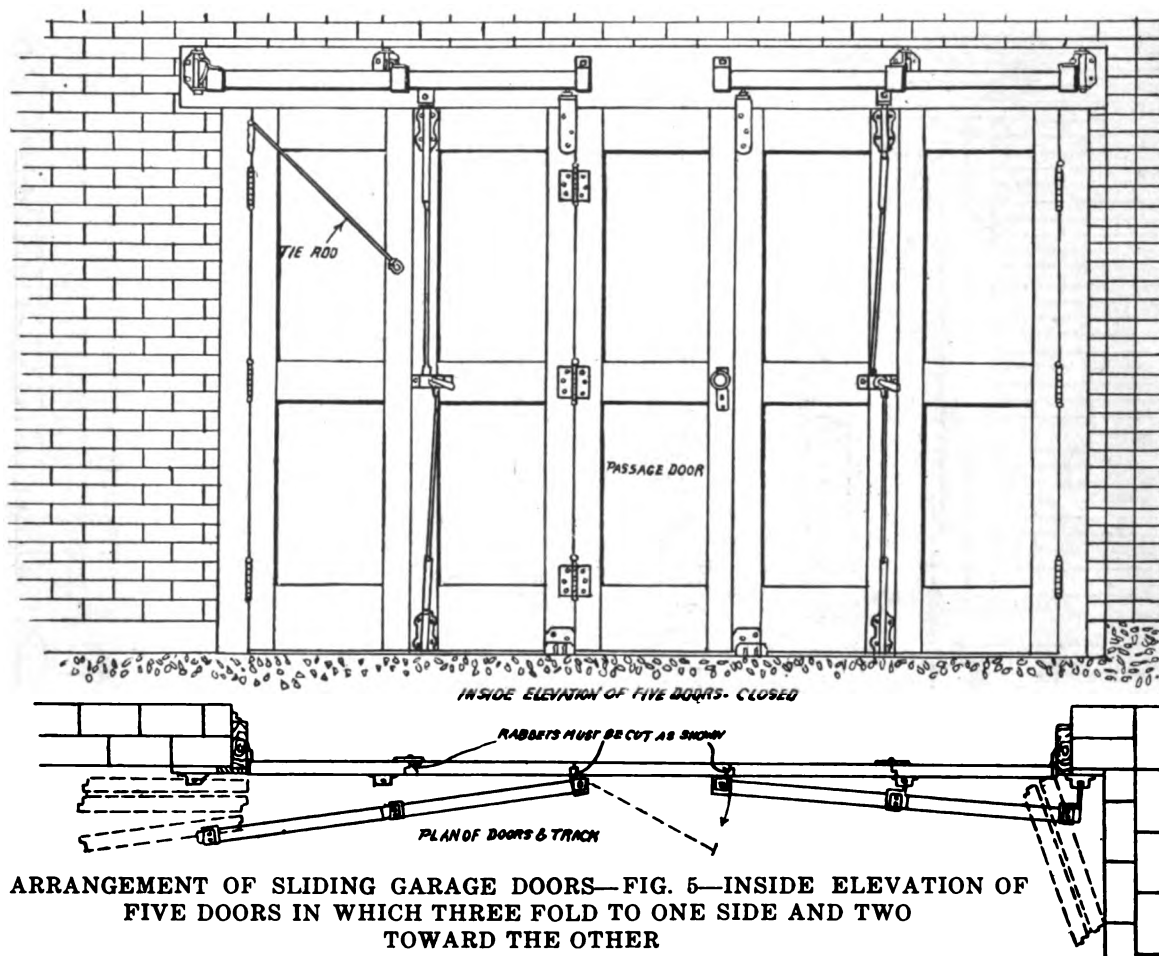

nailing of hard woods is not so common, as hard woods are often framed or bolted together. The subject seems to have had the minimum of study, for it is hard to discover the reasons that determine the size of nails or screws among wood-workers. A glance at the interior of any coasting boat will show that although every nail is clinched, a length of 3 in. is allowed for that purpose, while the spread of the head barely amounts to 1 in. The waste of iron in nails alone cannot be less than

from 20 to 25 per cent. Hard woods are more common in tropical than in temperate countries, and as they are frequently joined with nails, some system should be adopted to obtain the best results. It is useless to ask the carpenter to go into calculations about nails; he cannot do it, but he can make a simple experiment that will enable him to avoid splitting the wood.

A nail holds itself in place in two ways: by friction of its sides against the wood, and when clinched, by the resistance of the clinch which resembles a second but smaller head. The combined resistance of sides and clinch represent the total holding power of the nail. Square nails are usually tapered on two sides and parallel on the other two; the tapered sides should bear against the end

the holding power of the nail will be reduced and clinching will be a very imperfect remedy. If many nails of one size have to be driven, as in boat building, it is advisable to experiment on a piece of wood of the necessary thickness in order to find out the right size of the hole that will avoid splitting the wood, or bending the nail. When wire nails of a large size are used in drilled holes, the size of the hole should be such as will insure a good fit; and if the nail is to be clinched it should be softened at the point by heating to redness. The wire nail is hard drawn to enable it to be driven without bending in soft woods, but it does not clinch well for this reason, and therefore needs softening.

The holding power of nails and screws may be ascertained by a simple experiment. The nail may

grain of the wood, crushing it gradually as the nail enters; and when it is fully driven it bears uniformly against this end grain, crushing it without splitting. All woods when soaked in water or when green may be nailed with less risk of splitting than when they are dry, but there are limits to the depth that a long nail may be driven into any wood before it begins to bend, that is to say, where the friction of the wood overcomes the driving power of the hammer. When a nail begins to bend it shows that a hole must be made beforehand; and the size of the hole is a matter of some importance, says a writer in the *Indian Textile Journal*. Its object is to reduce the friction so as to allow the nail to be driven without bending, but if made too large,

be driven into an upright post leaving the head projecting just enough to be seized by a nail-puller. This instrument is then attached and weights added to the outer end until the nail begins to move. A bag loaded with stones will serve the purpose. The nail-puller consists of two levers formed by the extended handle and the projecting foot, and if the weight in the bag is multiplied into the length of the handle in inches and divided by the exact length of the foot, measured from the nail to the point of contact of the foot with the post, the result will be the holding power in pounds of the nail.

Nails that have rusted after being driven have an increased holding power, but if rusted before use they tend to make a slightly larger hole than a

smooth nail, because of their rougher surface. In cases where clinching would be liable to split the wood, nails may be cut and riveted over a small washer. This makes a strong and durable joint. There is also a way of clinching a nail within the wood that is at times useful. The point is filed away on one side to a wedge shape and then bent over the filed part until the point is level with the side of the nail. A hole is drilled to the size of the nail which is inserted with the filed surface parallel with the grain of the wood. When driven, the point takes the form of a hook and has a strong hold upon the wood. The point of this nail should be heated and softened so as to facilitate the turning of the point.

Nails driven in wood that is exposed to alternate wetting and drying are liable in time to work loose.

of the notch in the screw, and not a chisel point as is usually seen.

ESTIMATING AREAS FOR PLASTERING

In discussing how to estimate the combined areas of walls to be plastered, a builder suggests the following method:

Put down in two columns the lengths of the two sides of the rooms to be figured that have the same ceiling height. Add each column and multiply the totals by two for the four sides of the rooms; then multiply each by the ceiling height; this gives the square feet in walls.

Extend a third column from the other two by multiplying the two sides of each room together,

The wetting swells the wood and increases its dimensions across the grain, and as the nail is inelastic it is moved, a space forming at the point equal to the amount of swelling of the wood. When the timber dries the nail does not return to its original place, and if tapered it tends to move outward each time that the wood is wet and dried. For this reason wood structures bolted together and exposed to the weather require occasional screwing up.

Screws offer an even more interesting subject for experiment, for it will be often found that if the hole for a screw is carelessly drilled it has less holding power than a nail. The holes for screws in hard wood should be very carefully made in two sizes: for the neck and the screw respectively; and the point of the screw-driver should be of the shape

which when added, gives the square feet in the ceiling. Add the three totals together and divide by nine for the square yards in the job. Rooms having wainscoting and high base are figured separately.

Many architects have made a feature of level roofs used as porches and outdoor living rooms and we understand that the Portland Cement Association of 111 West Washington Street, Chicago, Ill., is offering compensation for good photographs of roofs thus utilized. The roofs are not limited to buildings of any special material, the desire being to know what has been done to make a roof a useful and an attractive feature of modern homes.

THE GREAT AMBITION OF OUR BOYHOOD

A FEW THOUGHTS SUGGESTED TO OUR
YOUNG MIND BY THE WORK OF THE BUILDER

BY W. LIVINGSTON LARNED

EVER since I can remember
I've wanted to be a Contractor,
And put up houses
And bridges and things,
And be able to say
Exactly what I thought
To brick masons.
As a kid,
It was my pet ambition.
I looked with awe
Upon Mr. Jones,
The stout, red-faced
Old Gentleman,
Who put up all the houses
Of any consequence
In Our Town.

* * *

I never could understand,
In my Youth,
How that astute gentleman
Could carry all those figures
Around in his head.
It was somethin' awful
To even think about,
When nine times seven
Was so deuced difficult.
Yes, sir,
He'd take
Just a plain piece of ground,
With nothing on it
But dirt
And some sand fleas
And then—
Then he'd commence to dig,
And piles of brick would pop up
And gravel,
And a white box
For mixin' stuff in,
And before you knew it
The bricks would be
In the holes
And another house
Was sprouting
In Our Town.

* * *

I recall distinctly
How I was impressed
By the little yaller shack,
Those carpenters built
On the outskirts
Of the lot.
It was
A Treasure Trove
Of wonder-things—

Kegs of nails,
And shingles,
And boxes of tools,
And paint—oh-e-e-e—
Blue and green and red paint,
With brushes you could
Dip in it with.
Then there was a row of linseed oil cans
And a sticky black bottle
Filled with turpentine.
Beneath this one
Meager roof
No Pirate Chief
Ever hoarded
So much gold.
On Sundays,
When the watchman was asleep,
Us boys
Would silently raise a sash
And climb in,
And my heart
Would well-nigh stop beating,
I was so happy.

* * *

We'd dip
Th' brushes
In the cans of paint,
And we'd swipe nails—
Six of every different size—
And we'd pray,
There in the gray, half-light,
That some good fairy,
Would come along,
And turn us into carpenters,
So's we could have
ALL th' nails,
And do nothing
But drive them,
All day long.

* * *

That was long ago.
Still,
The feeling concerning
The Contracting business
Is about the same.
I'd swop
My office job
Any day
For one like Mr. Jones'.
It isn't the money—
For I've heard,
Indirectly,
That contractors *DO* make
A little profit,
And it isn't the glory,

Or anything of *THAT* sort,
 It's just the Boyhood joy
 Of putterin' around
 Paint kegs,
 And white lead,
 And shingle nails,
 And lathes,
 And musty old boxes
 Of sinister tools.
 That's it—
 Th' love of little things.
 Maybe
 There's some of the magpie
 In me.
 Isn't that
 The bird
 That steals things

And takes 'em
 To its nest?
 Anyway—
 I want to be a carpenter,
 And if there's
 Such a thing
 As being born over again,
 I'd like to put in my request now
 For the Contractor thing.
 Think of it—
 Think of the mad joy,
 Of not running true to form,
 And buildin' a little home
EXACTLY
 As some
 Young married couple
 Really *WANTED* it.

THE PREVAILING FALLACY OF "FREE" PLANS

WHY THE PROSPECTIVE OWNER THINKS HE
 IS RECEIVING "SOMETHING FOR NOTHING"

BY NOBLE FOSTER HOGGSON*

WHEN, after many mental flights of enthusiastic exhilaration, a man makes up his mind definitely to proceed with a building operation, the first thing he thinks of is the matter of planning. He knows pretty well what he wants. He has been contemplating the project for a considerable length of time; he has the site and a certain sum of money which he expects to put into the operation. All preliminaries have been decided. He prepares to go shopping.

He has heard of "free" plans. Some one has told him that, by having several sets of sketches made by different architects, he may determine which architect displays the ability to best carry out his ideas and desires. So he gets in touch with a number of architects. He frankly tells each of them that it is a matter of competition, and that the plans which seem to suit his needs best will be selected; that only the winner of the competition will be paid for his work.

ONLY ONE CAN WIN

Only one of these architects has a chance to secure the commission for the proposed building operation. One of them will win; all the others will lose; and, strange as it may seem, the owner has obtained nothing "free."

The owner spoken of above, who thought he had received something for nothing, was like most people laboring under that impression—he had not. Free plans are not free. When the successful architect in this little competition was awarded the commission, the owner assumed the cost to which all of the losers had been put. How? Because through the practice of competition the successful architect

in this competition is possibly the unsuccessful member in many other competitions. In other words, the architect receives only one contract in several attempts. It costs him just as much to prepare the drawings for each of the unsuccessful attempts as it cost to prepare the drawings for which he is paid. Therefore the order he obtains must bear the cost of those he does not get. The owner, in the building operation the architect secures, pays a proportionate cost of all the jobs upon which the architect has spent his energy.

OWNER SHOULD PAY FOR ONE SET OF PLANS

An owner should pay for one set of plans—his own. Every person who has the desire to build is inspired by an ideal. It is his sincere wish to build enduringly and to attain harmony in building. He begins with the intention of having his building operations conducted successfully, satisfactorily, speedily, and economically. To obtain this result, building problems should be considered as a whole. The plans are a very important matter, but no more so than the other elements that enter later. If the plans are satisfactory, seeming to express the ideas of the owner and serving their purpose adequately, an important question to be answered is whether the intended structure can be erected for the amount that has been set aside for this purpose. And will that amount include the equipment, the furnishings and the decoration? If not, what additional amount will have to be added? Then is the time to decide these matters. The architectural part of any structure is the fixed, dominating element that controls everything else, the element to which everything else must conform. Once settled upon, it cannot be radically changed except at a great expense, and even then, only within certain limits.

*President, Hoggson Brothers, Builders.

A TILE AND STUCCO HOUSE IN WORCESTER

AN ARRANGEMENT OF ROOMS INVOLVING INTERESTING FEATURES—DETAILS OF CONSTRUCTION WORK

THE rapidly growing tendency toward fire-proof construction in connection with dwelling houses is exemplified in the many structures of this nature which are being erected year by year in all parts of the country. An excellent example of this tendency is found in the tile and stucco-coated residence which forms the basis of the present article. The half-tone picture on this page

mixture of cement mortar to which 10 per cent of lime was added. The joints in the wall above grade are raked out and pointed with white Portland cement.

The main walls of the house are of 8-in. terra cotta blocks having special dovetail scoring to serve as a key for the outside stucco, which is also a 1:3 mixture of Portland cement mortar. Where neces-

TILE AND STUCCO RESIDENCE OF MR. F. T. BLAKE AT WORCESTER, MASS.—
ARCHITECTS L. W. BRIGGS CO., OF THAT CITY

affords the reader an excellent idea of the appearance of the completed building while the other interior views give an idea of the finish of some of the principal rooms. The floor plans clearly indicate the general layout of the rooms and present a study in planning which the builder and prospective house owner will find of more than usual interest.

According to the specifications of the architects, the foundation walls are of field stone laid in a 1:3

sary Ruddy metal wall plugs were built in to serve as grounds for nailing strips.

Terra cotta slabs 1 in. thick are set under all floor beams to serve as bearing plates. Steel plates not less than 8 x 12 x $\frac{3}{4}$ in. are used under the ends of all beams resting on masonry walls.

Embedded at intervals of 5 ft. in the wall under the roof plate are $\frac{3}{4}$ -in. bolts 30 in. long and projecting 6 in. above the top of the wall for the

purpose of securely anchoring the roof plates.

The plates are 2 x 8 in., the wall and partition studs 2 x 4 in. placed 16 in. on centers, and the girders are flush with the floor joists and have 2 x 3-in. bearing pieces spiked to the sides. All floor joists are bridged with 1 x 3-in. strips and bearing partitions are bridged once in the height of each story with 2 x 4-in. pieces. Where cement wainscots occur extra studding are placed so as to make 12-in. bearings for metal lath.

Studs are doubled at all openings and the latter are trussed overhead where necessary. Where bearing partitions occur over each other, the cap of the lower partition forms the sill of the one above. Fire stops are cut in between the joists at all floors and partitions and between stair stringers as required by the building ordinances of the city.

The exterior tile walls of the house, including reveals and soffits of openings, the ceilings of open porches, as well as the cheeks of porches and dormers are covered with stucco. The ceilings and cheeks of porches are furred with a $\frac{3}{8}$ -in. steel rod stapled to the face of the boarding on the cheeks and furrings on the ceilings and covered with No. 24 gage "Hampton" iron metal lath securely wired to the steel rods with heavy galvanized iron wire. The stucco was applied in three coats, the first consisting

Main Floor Plan—Scale 1/16 In. to the Foot

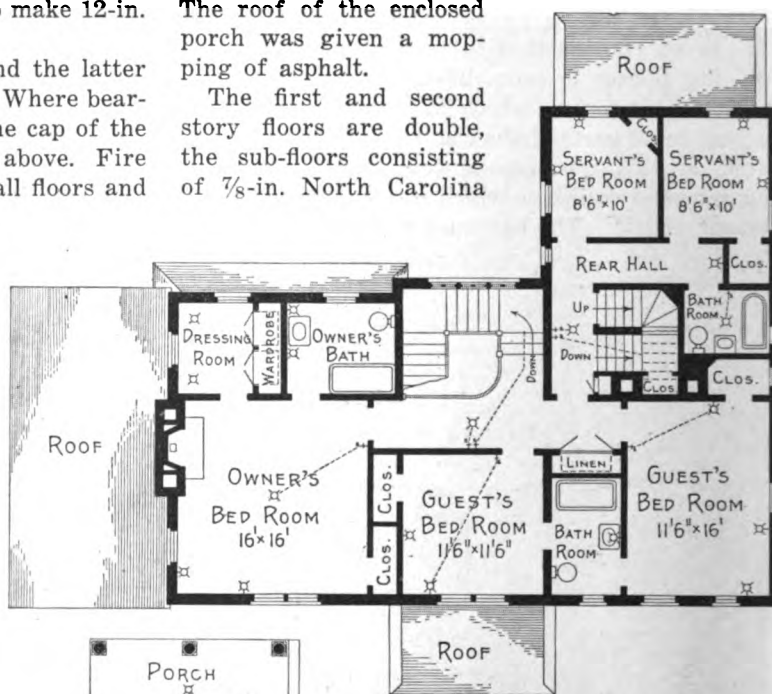

of one part Portland cement and three parts sand with not more than 10 per cent of lime putty. The stucco on metal lath had hair mixed with the lime putty in the proportion of 4 lb. of the former to 1 bbl. of the latter. The second coat consisted of one part Portland cement to $2\frac{1}{2}$ parts sand, while a final coat consisted of one part Medusa white Portland cement and two parts white sand. The final coat of stucco was mixed with Medusa waterproofing applied in strict accordance with the directions

of the manufacturers, the Sandusky Cement Company, Cleveland, Ohio.

All pitch roofs are covered with sheathing boards over which was placed one thickness of asphalt felt and over this in turn was laid unfading mottled green and purple slate $\frac{3}{16}$ in. thick with 3-in. head lap. All valleys were laid open and lined with 16-oz. copper 20 in wide.

The roof of the enclosed porch was given a mopping of asphalt.

The first and second story floors are double, the sub-floors consisting of $\frac{7}{8}$ -in. North Carolina

Second Floor Plan—Scale 1/16 In. to the Foot

pine laid diagonally and covered with 2-ply building felt. The finish floors are $\frac{13}{16}$ x $2\frac{1}{4}$ -in. face red birch, except in the kitchen, pantries and entry, where they consist of narrow strips of spruce smoothed for linoleum. The rear staircase hall and the service portion of the second story have finish floors of maple. The attic floor is of $\frac{7}{8}$ -in. No. 2 spruce.

The service portion in both stories of the house as well as the laundry, cellar and attic stairs are finished in North Carolina pine, the service portion having received one coat of primer and filler and two coats of varnish left in the luster.

The finish in the living room is Gulf cypress, while that in all other rooms is birch painted. The dining-room has a wainscot with molded base and cap and flush molded and raised five-ply panels.

The stairs are built on 2 x 10-in. stringers placed 12 in. on centers. The main stairs have $1\frac{1}{8}$ -in. treads of red birch and risers $\frac{7}{8}$ in. The landings are made to match the floors. The handrail is of red birch with spiral at the bottom supported on a turned post. The turned balusters are $1\frac{3}{4}$ -in. birch

with two to each tread. The angle posts are square with panel shafts and molded caps and drops.

In the living-room the wainscoting is of wood 5 ft. 6 in. high and in the dining room 3 ft. high. In the owner's and guests' bath rooms it is of tile 4 ft. 6 in. high and in the kitchen, pantries and entry it is of cement about 3 ft. high applied to "Clinton" galvanized iron lath.

Some of the built-in features include clothes chute, lined with $\frac{1}{2}$ -in. thick sheathing and having $\frac{7}{8}$ -in. panel doors about 18 in. high; wardrobe in the dressing room which has drawers at the bottom,

porch is paved with "Harvard" brick laid in Portland cement.

The inclosed porch has plastered walls and the trim is quarter-sawn white oak. The ceiling is sheathed with $\frac{7}{8}$ x $5\frac{1}{2}$ -in. face shiplap boards and has a cornice $3\frac{1}{4}$ in. wide. The jambs of the windows in the porch are plastered, and the frames cased with $\frac{1}{2}$ -in. plain piece and a small bead. The front of the inclosures of the porch have hinged wood lattice grilles.

The house here described was erected for Fordyce T. Blake on Military Road, Worcester, Mass., in ac-

VIEW IN THE LIVING ROOM LOOKING TOWARD THE REAR OF THE HOUSE

and recessed bookcases which have movable shelves.

The owners and guests' bath rooms have Herring-bone ceramic tile floors with joints of white Portland cement and 8 x 6-in. glazed tile wainscot with 6-in. sanitary tile base and 2-in. cap.

In the cellar is a No. 6 "Hoffman" instantaneous gas water heater with thermostatic automatic regulator.

The cellar is of concrete 3 in. thick and is finished with a coat $\frac{1}{2}$ in. thick, consisting of a mixture made up of one part Portland cement and two parts sand, laid before the base course set.

The outside trim is of Gulf cypress with the front entrance door frame of Western white pine. The porch columns are of white pine made by the Hartmann-Sanders Company, Chicago, Ill. The entrance

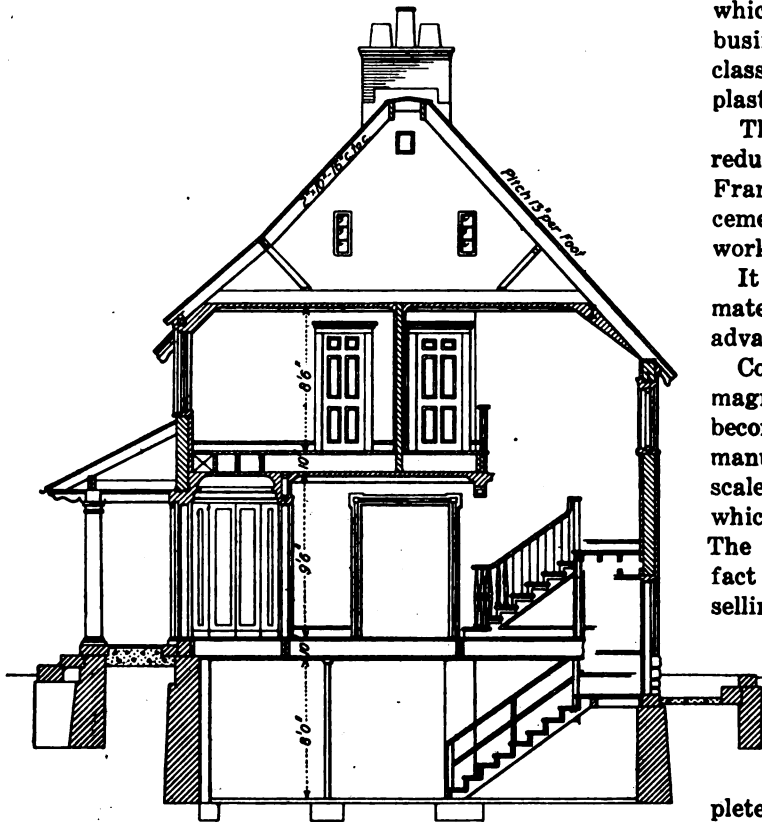

cordance with plans and specifications prepared by L. W. Briggs Company, architects, of that city.

SAN FRANCISCO MATERIAL MARKET

Our correspondent, writing under date of Nov. 7, says: San Francisco was rather well built up in anticipation of the Exposition last year, and thus far there has been no scarcity of accommodations, either as to business space or down-town or suburban living quarters. There has been a great deal of building planned during the last year, and most of the plans would no doubt have been carried out, were it not for the extreme cost of materials, which has stopped speculative building almost entirely, and

materially retarded ordinary dwelling construction. Small work, however, has been comparatively active of late, especially for business buildings of moderate size in the wholesale districts, and many mechanics still find employment in the construction of factory buildings in Oakland, Alameda and Richmond, as well as in San Francisco.

The price of structural steel has a decidedly deterrent effect, especially as to large buildings in which it is an important item. Besides the high price, deliveries are very poor, and several jobs of importance have been held up at great inconvenience

VERTICAL SECTION THROUGH VESTIBULE
AND MAIN HALL TAKEN ON A LINE JUST
TO THE RIGHT OF THE STAIRS—
SCALE, 3/32 IN. TO THE FOOT

on this account. Local steel shops, however, are now fairly busy on small work and no longer suffer much inconvenience because of the strike. Reinforced concrete has been largely used for factory buildings, but less in other lines. The reinforcing bar market shows less strength than was expected, as plans for many concrete bridges, which would have taken a large tonnage, have been held up. This class of material, however, finds an enormous demand in the Orient, and the local mills are finding an outlet for their surplus at high prices.

Despite the further advance of corrugated iron, the demand was quite active for a time last month, owing to the hasty construction of a number of large mining buildings of this material in Nevada, San Francisco stocks being drawn upon for the sake of prompt delivery. This material is also being used for a number of industrial buildings here.

With winter approaching, the demand for lumber is quieting down somewhat here, while shortage of cars and ships prevents the normal shipments to eastern and foreign markets. Prices hold fairly steady on all kinds of lumber. The freight on lumber by boat to San Francisco from Oregon and Washington ports is about \$6 per M., nearly twice the normal cost.

Brick prices remain steady and it looks as if the year will end with an unusually small surplus at the kilns tributary to San Francisco, most of which have had a full run all season. This is attributed largely to the effective campaign in favor of brick, which has gained this material more popularity for business buildings, and especially for the better class of homes. The situation in cement, sand, lime, plaster, etc., shows no particular change.

The Southern Pacific Railroad has announced a reduction in transcontinental freight rates to San Francisco, beginning Nov. 24, affecting brick and cement, iron and steel forms and molds for concrete work, crude and calcined magnesite, etc.

It is announced that, beginning Jan. 1 building material teamsters in San Francisco will get an advance from \$3 to \$3.50 per day.

Compositions for flooring, etc., in which calcined magnesite and oil are the principal ingredients, are becoming quite popular in California, and their manufacture is encouraged by the present large-scale development of California magnesite deposits, which are very large and of exceptional purity. The calcined material is also made cheap by the fact that several concerns engaged in calcining are selling the resulting carbonic gas for enough to pay the cost of calcining and leave a profit.

Plans long under way for the systematic exploitation in export markets of the Douglas fir lumber of Oregon and Washington are now taking shape. The Douglas Fir Export & Exploitation Company has completed its organization, with the backing of seventy-five mills doing an export business, representing an output of about 200,000,000 board feet of lumber annually. It is expected that the bulk of the export lumber business of Oregon and Washington will be handled through this concern, which is completing plans for the establishment of agencies and the inauguration of a great educational campaign at the principal foreign ports to which Pacific Coast lumber can be shipped.

SUMMER SCHOOLS AND MUNICIPAL CAMPS IN NATIONAL FORESTS

An increasing use of the National Forests for municipal camp sites and summer-school locations is reported by the Forest Service. Officials say that the National Forests offer unlimited opportunities along these lines besides the excellent opportunities for healthful recreation that the forests afford. Ample provision is made for campers and tourists, hunting and fishing in season being allowed. There are no restrictive regulations beyond those regarding forest fires.

Among the cities which have availed themselves

of the facilities afforded is Fresno, Cal., which has been granted a permit for the use of a 15-acre camp on the shores of Huntington Lake, in the Sierra National Forest. It is reported that the city will establish a camp in which outings during the summer months will be provided at low cost for 11,000 school children and their parents.

In the same forest a California State normal school is now occupying a tract of land which is rented from the Government under a long-term lease. A number of buildings have been erected, all of which, as well as many cottages and camps, are supplied with water from a water system installed by the Forest Service. In connection with the regu-

tract of land in the Angeles Forest has been rented and a large camp built at a cost of about \$8,000. This camp consists of a log and stone lodge, 46 furnished cottages, tennis and croquet courts, baseball grounds and handball courts.

LIEN LAW FOR PORTLAND

A joint committee from The Builders' Exchange, Building Material Dealers' Association, Central Labor Council, Planing Mill Owners' Association, Association of Building Owners, and Portland Realty Board, has approved four proposed amend-

THE DINING ROOM LOOKING TOWARD THE OPEN FIREPLACE, WITH THE DOOR TO THE SERVICE PANTRY JUST BEYOND

lar six weeks' summer course this school gives a course in woodcraft and general forestry subjects. The students visit the near-by Forest Service ranger station and lookout towers, and study the Government's methods of fire protection. Addresses on the work of the Forest Service are given by officials from time to time.

The Georgia State Forest School has a camp on private lands on the Georgia National Forest, where a summer course is given. A feature of this course is a series of talks given by members of the Forest Service stationed in the vicinity.

Los Angeles was the first city in California to establish a vacation camp in the National Forests. A

ments to Oregon laws and is proposing to submit them to the Legislature. The first proposes to limit the liability of bonding companies furnishing bonds on public work to one year after completion. The second requires notices that any property is "not subject to lien" to be filed with the county clerk, rather than merely posted on the property. The third would eliminate the necessity of notifying the owner of property within five days that deliveries of material have been commenced to a contractor on a job, as a prerequisite to filing a lien if the materials are not paid for. The fourth would remove the exemption of homesteads under the present lien law.

NEW PUBLICATIONS

Hendricks' Commercial Register. 1732 pages, size $7\frac{3}{4} \times 10\frac{1}{4}$ in. Bound in heavy board covers. Published by S. E. Hendricks Company, Inc. Price \$10.

This is the Twenty-fifth Annual Edition of the well-known Hendricks' Commercial Register of the United States especially devoted to the interests of the contracting, architectural, electrical, hardware, iron, mechanical, quarrying, engineering, mining, railroad, steel and kindred industries. It is in fact a complete annual register of producers, manufacturers, dealers and consumers connected with the industries mentioned and with multitudinous other industries of interest to buyers and sellers. The products are listed from the raw material to the finished article with the concerns handling them, from the producer to the consumer. There are about 350,000 names and addresses, with upward of 45,000 business classifications. There are 1512 pages of text and a comprehensive index of contents requiring 149 pages and covering over 50,000 trade references. For the first time a list of trade names, brands, titles of identification, etc., is published and its extent may be gathered from the fact that 202 pages are required for the purpose. These trade names are printed on tinted paper at the close of the book so that they may be quickly found, while the list furnishes ready reference for purchasing agents and prospective buyers to distinctive products manufactured by firms listed in the book.

An idea of the value of the work to those engaged in the building industry may be gathered from the fact that there are 27 pages devoted to the names and addresses of architects, 30 pages to building and general contractors, 22 pages to lumber manufacturers and wholesalers, 14 pages to brick manufacturers, 12 pages to masons' and builders' materials, 8 pages to sash, door and blind manufacturers, 4 pages to roofing manufacturers, 8 pages to makers of cornices and skylights, and 14 pages to hardware manufacturers. The volume is a storehouse of information along the lines indicated and has been compiled with great attention to all essential details.

Drawing for Builders. By R. Burdette Dale, M.E. 166 pages, size $8 \times 10\frac{3}{4}$ in. Illustrated by 69 figures and 50 plates. Bound in cloth. Published by John Wiley & Sons, Inc. Price \$1.50.

The literature of elementary architectural drawing has received a valuable addition in the book under review, for it has been written to meet the needs of carpenters, builders and students who have had no previous training in drawing and who therefore require a simple explanation of the fundamental principles of the art. It is intended for use in home-study instruction, either with or without assistance, and the matter has been made brief enough to eliminate waste of time.

The first thing required by a beginner is a knowledge of the use and varieties of the tools with which he is to work. This information is therefore given, together with instructions on how to lay out a drawing. A list of mistakes often made is presented, so that the student may gain some idea of the ordinary errors he is likely to make unless forewarned and therefore be prepared to avoid them. Instructions in lettering are also given.

After this preliminary knowledge is gained, the student requires practice in using his instruments before he can hope to successfully draw elevations and floor plans. Therefore practice is given in drawing straight and curved lines, this being followed by problems in geometrical and projection drawing. Further problems in manual training drawing include a bracket shelf, a taboret, tool and nail boxes, an arm chair, etc.

The student is then prepared to take up more difficult work and he is given the material which, be he carpenter, builder or embryo draftsman, he should know how to draw. Building details are presented, including various moldings, a detail of a baluster, doors, windows, cornice construction, medicine case, stairs, various built-in features, floor plans, elevations and details of construction in brick, tile and terra cotta. In the more advanced drawings, the student is provided with a sketch, sufficient scale drawing and description for him to work up the finished drawing, all of which teaches him to *understand* instead of merely copying.

The author's activities as Assistant Professor in Charge of Vocational Courses in Engineering and Correspondence Instruction of the Engineering Extension, Iowa State College, have afforded him opportunities to become acquainted with the best practice along the lines indicated above and to understand how to present the material in such a manner as to interest and instruct those for whom the book is especially intended.

TO HELP REHABILITATE FRANCE

Noble Foster Hoggson, president of Hoggson Brothers, the well known New York builders, is now in Europe as a member of the American Industrial Commission to France. The commission is engaged in making a survey of the devastated section of France, to determine what America can do toward the rehabilitation of her sister Republic. Mr. Hoggson is making a particular study of the question of industrial housing, town planning, the need for factories and other commercial structures, not only as to their planning and construction, but also as to their equipment.

Work has been commenced on 50 brick houses in Waterbury, Conn., which are to be tenanted by the employees of the Scovill Mfg. Co.

MEETING OF MICHIGAN BUILDERS' EXCHANGES

FOURTH ANNUAL CONVENTION HELD IN LANSING,
NOVEMBER 15 AND 16, WITH LARGE ATTENDANCE

THE fourth annual convention of the Associated Builders' Exchanges of Michigan took place in the city of Lansing on November 15 and 16, the sessions being held in the House of Representatives at the State Capitol. There were in attendance about 150 delegates from the various sections of the State, notably from Grand Rapids, Muskegon, Flint, Saginaw, Jackson, Kalamazoo, Detroit and Lansing. A few others from Marshall and other points scattered throughout the State were also present.

The convention was called to order at 2 o'clock on the afternoon of November 15 by President Wilcox, introducing Hon. J. C. Reutter, the Mayor of Lansing, who gave a very cordial address of welcome to the visiting delegates. The machinery of the convention thus being set in motion, it continued on routine business, reports of officers, etc., etc., during the afternoon, adjourning at 5.15.

THE BANQUET

A banquet served in the Chamber of Commerce Building by the ladies of the Presbyterian Church of Lansing was tendered the delegates at 6.30 o'clock of that evening, and proved to be a most enjoyable affair from all angles. The meal was attractively served, and, consisting of home cooking, was exceptionally enjoyed. Music by a local orchestra and by a large choir of well-drilled boy voices from the Industrial Home for Boys was a most pleasing feature, and called for repeated encores. The boys sang with gusto, and their voices blended beautifully. Other entertainment was furnished, and a list of speakers was called upon, who entertained very agreeably.

Following the banquet, a general bowling tournament was engaged in at the Lansing Alleys, a more of a get-together spirit than in any sense of professionalism in this particular sport.

THURSDAY MORNING SESSION

The morning session of Thursday, November 16, was called to order at 9 o'clock, and was probably the most interesting session of the entire convention. A very illuminating talk was given by Joseph G. Haufman, secretary of the Michigan Manufacturers' Association, along lines of "Laws Inimical to Building Interests," which from all appearances at this time would be introduced at the coming session of the Legislature. This included changes to the present Workman's Compensation Law, as well as other matters of extreme importance to the building trades. Frank G. Campau, attorney for the Builders' Exchange of Grand Rapids, also added very materially to the information, as did Robert K. Orr, assistant secretary of the State

Association, who was formerly the manager of the Industrial Department of the Accident Fund of the Insurance Department of the State of Michigan. Much discussion was had on the subject presented, and the entire forenoon was consumed in this particular.

A number of visiting architects, consisting of the president and members of the legislative committee of the Michigan Society of Architects, were present at the sessions and joined in the discussions. A most friendly feeling was shown to exist between the architects and contractors.

The result of this discussion was that the president was instructed to appoint a permanent legislative committee to unite and work with legislative committees of other associations in a combined effort to watch carefully all laws inimical to the building trades and introduce others which they thought might be of some value.

A committee was also appointed to make the necessary recommendations for assessments and the manner in which money might be raised to pay any expenses in this connection. This committee recommended that the per capita tax for the ensuing year be fifty cents per member, that the Executive Board should be authorized to make any other assessments they thought necessary in order to cover any expenses in connection with the legislative matters which they regarded important.

ELECTION OF OFFICERS

The meeting adjourned at 3 o'clock in the afternoon, after electing the following officers:

President.....Geo. B. Schroeder, Grand Rapids
First Vice-President.....C. O. Wheeler, Detroit
Second Vice-President.....Fred C. Trier, Saginaw
Secretary and Treasurer..Chas. A. Bowen, Detroit

The latter appointed for his assistant for another year Robert K. Orr of Lansing.

Flint was selected as the next place at which the convention would be held, the date for same, however, being left in the hands of the Executive Committee, as is the usual practice.

A NEW THIRTY-STORY LOFT BUILDING

Among the plans filed with the Bureau of Buildings for the Borough of Manhattan in anticipation of the passage of the zoning ordinance in July last were those for a thirty-story hotel. This project, however, has just been replaced by plans for a thirty-story loft building to cost in the neighborhood of \$800,000 and which will occupy the plot at

the southwest corner of Broadway and Forty-eighth Street, New York City. The plans for this improvement which were filed Oct. 13 were prepared by Architect E. D. Litchfield.

According to the architect's design the structure will have twin-towers each about 50 ft. in area which will make it the tallest building of its character in this country if not in the world and sharing this distinction with a similar structure erected a few years ago in West Fortieth Street. The main feature of the new building will be its exceptional lighting facilities, protected for all time above the fourteenth story by the new ordinance which limits the height of buildings to that level in that particular section of the city.

The southerly line of the site of the new building extends for a distance of 140 ft. along the line of the Strand Theatre property, this low structure increasing the lighting facilities of the proposed building which has been planned for immediate construction on the assumption that the opening of the Seventh Avenue and Broadway subways will soon make this one of the important trade centers of the city.

OCTOBER TENEMENT HOUSE CONSTRUCTION IN NEW JERSEY

The following compilation shows the amount of tenement house construction in New Jersey in October, compared with the same month a year ago:

Municipalities	1916,	1915,
	Estimated Cost	Estimated Cost
Athenia	\$8,000
Atlantic City	33,000
Bayonne	6,000	\$15,000
Belleville	5,000
Bloomfield	3,000
Cliffside Park	3,000
East Orange	78,000	5,000
Elizabeth	7,000
Garfield	5,000	8,000
Harrison	5,000
Hoboken	16,000
Irvington	10,000	31,000
Jersey City	108,000	115,000
Kearny	16,000	11,000
Newark	109,000	231,000
North Bergen	6,000
Passaic	4,000	14,000
Paterson	7,000	5,000
Town of Union	25,000
Weehawken	110,000
West Hoboken	24,000
West New York	80,000	11,000
Woodcliffe	14,000
Total	\$522,000	\$606,000
Alterations	25,900	23,600
	\$496,100	\$582,400

The noticeable features are the heavy falling off in operations in Newark and Weehawken.

ROOFINGS AND THEIR MARKET IN LIBYA

Until a comparatively recent date there was no market for ready roofings in Libya, North Africa, but Italian influence has now changed this condition; new types of roofs have been introduced, and a gradual increase is likely in the utilization of such products; but to make the demand important great changes must take place in the habits and purchasing power of the native masses. Of the 1,050,000 inhabitants in Libya, 95 per cent are Arabs, and a

large proportion of these are nomadic. Natives who live in the oases have fixed habitations, simple dwellings of stone, sun-dried bricks, or packed earth, with roofs fashioned from datewood rafters overlaid with palm leaves and straw, the whole being covered with a coating of lime plaster. In coast towns, structures are either of stone or brick, with division walls or like material.

All roofs in this last class of buildings were formerly flat, and covered with lime concrete. With the arrival of the Italian forces in 1911, the need for military accommodations caused great building activity. Temporary structures were erected of wood, roofed with Eternit, corrugated iron, pariod, or rubberoid. Later, similar quarters were built at interior points and knockdown houses of German origin were introduced. In buildings of a more permanent character, reinforced concrete, concrete blocks, bricks, and Eternit have been used.

It is estimated that in 1912 imports of roofing materials totaled not less than \$50,000, and in 1913 about \$40,000, fully 75 per cent being "Eternit," an artificial stone said to be composed of asbestos, other mineral substances and chalk, fixed and hardened with acids. American participation in 1912 amounted to \$2,000, and in 1913 to \$4,100. At present there is a lull in building operations, and the future demand is uncertain. The demand for building papers other than roofing is limited.

ARCHITECTURAL LEAGUE OF NEW YORK

According to the circular of information just issued, the thirty-second annual exhibition of the Architectural League of New York will be held in the building of the American Fine Arts Society, 215 West Fifty-seventh Street, from Feb. 4 to Feb. 24 inclusive, 1917. The exhibition will consist, as has its predecessors, of drawings and models of proposed or executed work in structural, decorative and landscape architecture; sketches and finished examples of decorative painting; sketches, models and finished examples of decorative and monumental sculpture. Competitions to be held under the auspices of the Architectural League, include one for the Henry O. Avery prize for sculpture, the subject being a triumphal arch commemorating the Renaissance of Peace. It is designed to be located in a public square of a large city formed at the intersection of wide avenues. There is also to be a competition for a special prize of \$300 for the best design submitted by an architect, sculptor and mural painter in collaboration. The Avery prize will be awarded on the sculptural element and the award of the collaborative prize will not render the work of the collaborating sculptor ineligible therefor.

According to the annual report of Municipal Architect Snowden Ashford, there has been an increase since 1898 of 60 per cent per cubic foot in the cost of buildings erected in the District of Columbia. He predicts a further increase during the next year.

CURRENT NEWS OF BUILDERS' EXCHANGES

NEW QUARTERS OF CLEVELAND EXCHANGE —A BUILDING EXHIBIT FOR ATLANTA, GA.

Cleveland Exchange Has a Housewarming Party

SEVERAL hundred members of the Builders' Exchange in Cleveland attended a house-warming party in the new quarters on the third floor of the Rose Building, Wednesday evening, Oct. 25. The exchange has recently fitted up what is considered to be one of the best headquarters for builders in the United States, comprising about 16,000 square feet of space. The floor has been divided into compartments for exhibits and offices occupied by members of the organization. Upward of \$18,000 have been expended in the improvements.

The quarters comprise a large main floor, which is connected with an additional section through an arcade of exhibits. The architectural plan was prepared by Messrs. Hubbell & Benes, architects, and many artistic features have been introduced, making the exchange very attractive. Some of the exhibits are costly, representing the most modern ideas in presenting possibilities of materials and appliances. Other features of the new exchange are a "lounge" for members, a large committee room, plan rooms, coat room, and assembly hall capable of seating upward of 200 persons.

At the house-warming party the wives and families of members were included. An orchestra provided music during the evening, and there were several vocal numbers, including solos by F. J. Dresser, a member of the Board of Directors. Addresses were made by President Klumph and other speakers. Following this part of the program dancing was enjoyed in the assembly hall. Refreshments were served, and altogether a most enjoyable evening was afforded under the direction of the entertainment committee of the exchange.

Weekly Meetings of Grand Rapids Builders' and Traders' Exchange

The regular weekly meetings of the Builders' and Traders' Exchange of Grand Rapids, Mich., started on Nov. 22. In announcing the resumption of these enjoyable affairs, Secretary A. H. Shank said: "We will have four noon meetings and the fifth will be in the nature of a banquet, to be held at 6:30 p. m. in some one of our hotels. At this fifth meeting reports of all committees will be heard and such other business as will be necessary will come before the membership. We will, of course, have a good speaker at this meeting for the members' entertainment."

Activities of the Pittsburgh Builders' Exchange

At a recent noonday luncheon of the Builders' Exchange of Pittsburgh, Pa., a movement was started looking to securing for the city the 1918 convention of the National Association of Builders' Exchanges. A club has been organized in Pittsburgh to attend the 1917 convention to be held next February in Atlanta, Ga., and the idea is to secure a large number of recruits to go to Atlanta and boom Pittsburgh. Incidentally Robert K. Cochrane of Pittsburgh is a candidate for the presidency of the national organization, and a rousing campaign for him is under way.

President S. P. Tribble has appointed a committee to assist the entertainment committee, also a paper publishing committee and a nominating committee.

Permanent Building Exhibit for Atlanta

Members of the Builders' Exchange of Atlanta, Ga., have decided that that city must stand among the progressive communities housing permanent building exhibits. While the plan is still more or less embryonic, a committee has been appointed by President C. W. Bernhardt to investigate the various angles of the undertaking. This committee is composed of C. G. Bradt, Fair Dodd, T. T. Flagler, J. M. Clayton, R. M. Walker, Edgar Alexander, D. A. Farrell, L. T. Whitfield and A. A. Craig.

Luncheons of Philadelphia Builders' Exchange

The weekly luncheons of the Builders' Exchange of Philadelphia, Pa., are one of the enjoyable features instituted by that organization, and many interesting hours are spent in listening to the talks made by various guests. Among those who have recently helped to entertain the members by interesting remarks are Major Hollenback, third vice-president of the exchange, who, on Oct. 12, gave an enjoyable talk on "The Life of a Soldier," in which he spoke of his experiences for three months on the Mexican border. On Oct. 19 E. J. Cattell addressed the organization, and on Oct. 26 Michael Francis Doyle, one of the counsel for the late Sir Roger Casement, delivered a talk upon present day conditions in England. On Nov. 2 Thomas A. Daly addressed the exchange.

SOUTHWESTERN CONCRETE SHOW

Arrangements are being made for holding the first annual convention of the Southwestern Concrete Association in Kansas City, Mo., Feb. 19 to 24 inclusive, 1917. There will also be held in connection with the convention, a concrete show of which Charles A. Stevenson of 1413 West Tenth Street, Kansas City, Mo., is the chairman. We understand that it is the expectation of the management to go into the convention with at least a membership of five hundred.

BIRMINGHAM MODIFIES ITS ANTI-SHINGLE LAW

Some time ago the city of Birmingham, Ala., adopted a drastic anti-shingle ordinance which time has demonstrated to be a failure, and it has recently been annulled. A new ordinance which has been passed forbids the use of wooden shingles in the restricted business districts, but very materially modifies the regulations against the use of shingles in the residential districts.

It is estimated that there are 63,590 brick and 26,576 frame buildings in the District of Columbia.

BRIEF REVIEW OF THE BUILDING SITUATION

BUILDING OPERATIONS FOR OCTOBER SHOW 23.6 PER CENT INCREASE OVER OCTOBER, 1915

THE activity in the building industry as contrasted with the current period a year ago continues to make progress and reports from 121 cities of the country show a gain in the estimated cost of new construction work in October of 23.59 per cent, as compared with the same month last year. The figures available show that all sections of the country are reflecting the improved conditions, but it is particularly noticeable in the extreme Western section and on the Pacific Coast.

There are forty-seven Eastern cities reporting which show a gain of 24.95 per cent over October last year, this being due in large measure to the greater amount of new construction work planned in Hartford, New Bedford, New Haven, the Borough of Manhattan in Greater New York, Philadelphia, Portland, Reading, Rochester, Schenectady and Worcester. The accompanying table affords an idea of the situation in the Eastern section of the country.

CITIES OF EASTERN STATES

	October, 1916	October, 1915
Allentown	\$128,535	\$154,725
Altoona	96,869	84,229

Work has been commenced upon a steel skeleton frame theater, store and studio building in Los Angeles, Cal., which will be twelve stories in height and the theater auditorium will seat 3000 people.

*No. 88 Adjustable*

YOUR REPUTATION

as a reliable contractor or carpenter depends largely on the satisfactory service rendered by material which you use, plus your knowledge of the proper method of installing such materials.

If any part of the completed building goes wrong, your customer kicks not only to you but usually to everybody who will listen. As a result your reputation as a reliable contractor suffers.

There is nothing about a barn used more than the sliding doors. There is nothing causes more annoyance than sliding doors which do not work easily.

You can avoid a lot of trouble by using Storm-Proof Hangers and Rail. They are easily installed and give long and satisfying service.

Storm-Proof Rail Requires no housing—a saving to you in labor and lumber. It is strong and sturdy, and will support all the weight the hangers will carry. Holds hangers firmly in place and is bird and storm-proof. Made in convenient lengths.

It is to your interest to investigate the superior merits of these goods. A catalog will be mailed upon request. Your dealer's name will be appreciated.

Builders' Appliances and Equipment

Some Things of Special Interest to Those Having to do with the Various Branches of the Building Business

New Method of Making "Classik" Steel Ceilings.

It is a well-known fact that manufacturing methods in all lines are constantly changing to the end that the

Fig. 1—New Method of Making "Classik" Steel Ceilings

greatest degree of efficiency may be secured. For years the majority of steel ceilings were made by the drop-hammer method of stamping the steel sheets. This method, however, has been dispensed with in the case of the Berger Manufacturing Company, Canton, Ohio, and its "Classik" steel ceilings are now stamped on a new, original and specially designed draw press under 900 tons pressure. This enormous pressure, it is claimed, assures absolute uniformity in depth, detail and size, each plate being pressed separately and is an exact counterpart of the others. Skilled artisans are continually originating new and distinctive designs in clay and from these are made the dies from which the steel ceilings are reproduced. The "Classik" line comprises hundreds of attractive patterns, each designed to harmonize with a particular type of architecture. One of these is illustrated in Fig. 1. Another distinctive feature of "Classik" ceilings is the improved bead and button construction which closes the joint tightly without tamping and calking. This construction is such that after a ceiling is erected, it is said to have the appearance of a single steel sheet. The company has issued a handsome catalog illustrating and describing the "Classik" steel ceilings and a copy will be sent to any interested reader who may make application for it.

Philadelphia Office of Standard Scale & Supply Co.

The Standard Scale & Supply Co. has moved its Philadelphia office, warerooms and Service Department from 35 South Fourth Street, to 523 Arch Street, the building having a depth of nearly 300 ft., extending through to 518 Cherry Street. These larger quarters are necessary to take care of the various departments and stock of Concrete Mixers, Hoisting Outfits, Power Pumps, Gasoline and Oil Engines, Scales and Trucks,

as well as Repair Parts for Engines, Hoists, Mixers, Etc., which are carried at all branches of this company in connection with a special Service Department operated to give the advantage of quick service and repairs in case of adjustments or breakdowns.

Peerless Molds for Concrete Silos

The rapid increase in silo construction throughout the country renders more than ordinarily interesting the Peerless molds for monolithic concrete silos and the line of straight wall molds made by the Enterprise Concrete Machinery Co., 532 First National Bank Building, Chicago, Ill. The silo equipment is made in 5, 6 and 7½-ft. heights, the size used governing the daily capacity. In Fig. 2 is shown the "forms" when set up, the 6-ft. mold being made in two 3-ft. sections and the 5-ft. mold consisting of two sections of the 7½-ft. mold, each of which is 2½ ft. high. It will be seen that the design provides for a chute, with continuous doorway and steel doors, of which the company claims to be the originator. The equipment comprises a mold with chute sections, door jamb forms, a form for roof cornice, combination derrick and scaffold with four jacks for raising derrick-scaffold and outer sections of mold; an adjustable, pivoted cement hoist, two drop-bottom buckets, two raising hooks, two drop ladder hooks, a complete set of clamps, spacers, collapsing plugs and lock or wedge fastenings. In the Peerless system no center-mast is required, as formerly, which has been discarded for the simple, less complicated and more efficient truss scaffold and derrick combination that is carried right

Fig. 2—Peerless Molds for Concrete Silos

along with the mold as it works upward. Four small jacks, with a man at each jack, are sufficient to quickly and easily raise the derrick-scaffold to receive the ring of mold ready to be raised, and the same procedure lifts

the section of mold, as shown in the accompanying illustration. Whether using a two or three-section mold, the operation is the same. The lowest ring of the mold is always brought to the top and one ring filled at a time, reinforcement and ladder iron being installed at the same time. The company uses and recommends triangular mesh reinforcing, made from cold-drawn steel wire, which is furnished in rolls of 150, 200 and 300-ft. lengths and suitable widths. The molds are made up of black stock, unless otherwise ordered.

New Stanley Garage Door Hinge.

A hinge provided with weather-tight ball bearing washers fitted between its hinge joints and especially designed for heavy garage doors has just been placed upon the market by the Stanley Works, New Britain,

Fig. 3—General View of the Hinge

Conn., as an addition to its line of garage hardware. This new hinge swings the door completely clear of its opening and therefore is particularly adaptable to garages with narrow entrances. The strap is 24 in. long and is provided with ornamental corrugation, which adds to its strength and general appearance. The hinge is easily applied, as mortising is unnecessary. Two of the screw holes in the pad are exposed on the outside and three screw holes are covered by the long leaf, so that when the door is closed the hinge may not be removed. In order to use this hinge the casing should be flush with the face of the door. In Fig. 3 is shown the general appearance of the hinge itself, while Fig. 4 represents a horizontal section through the door and frame at the point where the

Fig. 4—Horizontal Section Through Door and Frame at the Point Where the Hinge is Applied

hinge is applied, and by means of the dotted lines shows how the door is carried away from the opening, leaving the entire entrance unobstructed. This new garage hinge is made in dead black japan, plain japan, Stanley sherardized, or in dead black japan over Stanley sherardized.

The company has recently issued a catalog in which this new hinge is illustrated and described and a copy of it will be sent to any builder who may make application for it. The hinge is packed one pair in a box with 2-in. No. 20 wood screws. The hinge, however, is made with combination holes for either screws or bolts and whenever specified, $\frac{3}{4}$ x 3 $\frac{3}{4}$ -in. carriage bolts for the strap and 2-in. No. 20 wood screws or $\frac{3}{4}$ x 2-in. lag screws for the pad will be furnished.

Patent Granted for Surface Sealed Beaver Board.

Builders throughout the country will be interested in learning that Beaver Board Companies, Buffalo, N. Y., has been granted a patent covering the method by which Beaver board is surface sealed and sized to render it moisture-proof. The point is made that the surface sealing of Beaver board not only protects the front surface but gives a double coating on the back, which is a vital point every wall-board user should consider. All wall board is painted on the front and receives at least that much protection on that side. It is the back, however, where occur most of the moisture and temperature changes, and Beaver board, as a result of this patented treatment, is equally protected on both the front and back after painting. The patent in question grants Beaver board the exclusive right to be protected by this surface scaling and sizing treatment. A letter sent out by the company and of the folder type carries a photo-reproduction of the patent specification in question and there are also shown tests which demonstrate how completely this patented surface sealing makes Beaver board moisture-proof.

Asbestos Roofing and Shingles.

The question of fire resisting materials as roof coverings is always an interesting one, and the two new catalogs which have been prepared by the H. W. Johns-Manville Co., 296 Madison Ave., New York City, N. Y., contain information likely to command the attention of builders, architects, engineers, etc., the country over. One, entitled "J-M Transite Asbestos Shingles," was prepared for the attention of the architect and the home owner and contains numerous halftone illustrations of residences, churches, garages, barns, etc., which have been covered with these shingles. Asbestos shingles are a combination of asbestos rock fibre and Portland cement compressed under hydraulic pressure, the claim being made that their rock-like base and tough, resilient strength make them unaffected by time, fire or the elements. The various sizes and shapes of shingles are illustrated, together with the manner of applying them, in the styles known as American, Hexagonal and Diagonal, all of which are fully described. Prices for the various shapes and sizes, their weight and other interesting information are also given. These shingles are furnished in various colors. A page entitled "Handy Data on Roofs from Leading Authorities" contributes to make up an extremely interesting catalog.

The other catalog is entitled "Johns-Manville Corrugated Asbestos Roofing," a large part of which is devoted to illustrations of a few of the many large buildings, plants, etc., where this type of roofing is said to be giving "satisfaction under severe conditions." Corrugated Asbestos Roofing is made of a perforated metal sheet, which acts as a reinforcing, to each side of which is applied plies of asbestos felts thoroughly impregnated with asphalt and cemented together by a combination of Trinidad Lake and other natural asphalts. The edges of the metal core are overlapped with the asbestos covering, and for further security the edges are bound with asphalt impregnated tape. This roofing is applied in the same manner as corrugated iron and can be laid directly on the purlins. It is said that no expensive cementing

(Continued on page 78)

"I Am the Neponset Man"

"They called me that at first to jolly me.

"They didn't believe I had shingles that couldn't crack, rot, rust or rattle loose.

"But now the name Neponset is my capital. The first job where I used

NEPONSET TWIN SHINGLES

broke the ice for me. That one job led to a second, and the two soon became four. And so my business grew.

"Every one of these red and gray roofs here in town is mine. And many of the others, too, for I got a reputation as a roofer on account of my success with Neponset Shingles."

The same materials are used in Neponset Shingles as in the well-known Paroid Roofing, Neponset Wall Board, Neponset Waterproof Building Paper and Neponset Floor Covering are other well-known Neponset products.

Why Not Make Every Room Habitable?

Almost every home builder economizes somewhere. Often a room is left unfinished. In such a case you can give that extra bit of service that is so well appreciated.

Recommend that it be finished with

NEPONSET WALL BOARD

There are two finishes to choose from, and both are waterproofed to prevent warping.

If you do not know Neponset Wall Board you can not know the possibilities that lie in this substitute for lath and plaster. Full information upon request. Write to-day.

We want a carpenter in your town to be known as the "Neponset Man." Will you be the one? Send coupon today for particulars.

or special jointing are required. A valuable feature of the catalog is the number of details given of the various parts of a building and the proper method of applying asbestos roofing thereto.

"Kno-Burn" Corner Angles

Builders throughout the country are likely to be interested in the corner angle for preventing the cracking of plaster at the corners of rooms, which has been introduced to the trade by the North Western Expanded Metal Company, 904 Old Colony Building, Chicago, Illinois, and a general view of the application of which is presented in Fig. 00. There is nothing complicated in regard to these angles as they consist simply of strips of "Kno-Burn" expanded metal lath cut

Fig. 5—The "Kno-Burn" Corner Angles

8 in. or 12 in. wide and which can be bent on the job to fit the corner. The usual practice is to tack one side of the sheet either 4 in. or 6 in. away from the corner, depending upon the width of the sheet, and then with a hammer or hatchet drive the sheet into the corner and tack the opposite side. A good idea of the appearance of the corner after it is in place may be gained from Fig. 5 of the illustrations. The stock sizes of the corner angles are 3 x 3 in. and 4 x 4 in., each size being in 8 ft. lengths.

New Offices and Laboratory of Sanford E. Thompson.

Readers of the BUILDING AGE will be interested in learning that Sanford E. Thompson, the well-known consulting engineer and whose contributions on concrete work appeared some time since in these columns, has opened new offices and laboratory in the Federal Street Building, Boston, Mass., these replacing both the Newton Highlands and the Milk Street offices. The laboratory equipment has been developed as a result of a great number of special cases requiring apparatus, as for example a concrete saw and a 125-ton compression machine, not usually found in laboratories making only routine tests, which renders it possible to handle work of an original nature. It is interesting to state that association in a consulting capacity with large and important constructions in reinforced concrete and steel as well as many cases requiring particular advice and decisive reports on materials, methods, cost analysis and economical plant operation have peculiarly fitted the Thompson organization not only for original design and construction and tests but for investigations in-

volving complex problems. Associated with Mr. Thompson is William O. Lichtner, a well-known civil and mechanical engineer.

New Type of Casement Window Stay.

A new type of casement window stay has just been placed upon the market by the Monarch Metal Weather Strip Co., 4121 Forest Park Boulevard, St. Louis, Mo. The feature is that no hand adjustment is necessary, as the fixture is entirely automatic and the "Monarch" is said to hold the window in any position desired, without strain or rattle. The fixture is attached to the upper part of the window and is invisible when the window is closed. The construction consists of brass tubes fitted on the telescopic principle, sliding in or out as the window is opened or closed. The inner tube is provided with two "friction shoes," fitted to and pressed against the walls of the outer tube by the action of an expanding member. This is said to hold the window securely at any angle and to eliminate all vibration and noise. The stay is furnished in a polished brass finish and other finishes are supplied when desired. The new stay is illustrated and described in a booklet entitled "Entirely Different," which can be had upon application to the address above.

Ventilation of Farm Buildings.

It is a well known fact that a sufficient supply of fresh air is essential to the welfare of live stock, for they cannot thrive if the barn in which they are housed is poorly ventilated. The stock which are in the pink of condition generally receive the cheapest gift the farmer can give them, and yet one which is as important as the best food, namely, fresh air. The old-style wooden monitor or cupola has many drawbacks, and efficiency is better promoted by a ventilator with more positive characteristics; that is, one which will

create a uniform up-draft at all times, regardless of outside wind pressure and weather conditions. The scientific arrangement of bands and curved metal shapes of the Buckeye Cupola Ventilator is such as to cause, it is said, the slightest breeze to create a vacuum in the ventilator head, which makes a distinct suction in the cupola and thus draws the foul air from the barn. A simple explanation of the scientific reasons as to why pure air is important and the relation between fresh air, health and efficiency is explained at length in a new booklet issued by the Thomas & Armstrong Company, London, Ohio, and entitled, "The Proper Ventilation of Farm Buildings." The parts and construction of the Buckeye Ventilator are herein illustrated and described, a full page drawing showing the cross-section of a barn with the ventilator installed. There are also numerous illustrations of the ventilators in use and letters from satisfied users thereof, together with a handsome double page in colors showing a group of farm buildings equipped with Buckeye ventilators, and with the contented-looking cows occupying the foreground of the picture.

A New Sound-Absorbing Stone.

Our readers will be interested in the official announcement of the Johns-Manville Company, through C. M. Swann of its General Acoustical Department, that the company is now ready to furnish J-M Akoustolith—a new sound absorbing stone. The progress of the science of acoustics, and the demand for a structural material which should absorb sound have resulted in the production of this acoustical stone, which has a degree of absorption comparable with hair felt of equal thickness. This new production opens up great possibilities to the architect and builder on account of its durability, lightness, beauty of texture and flexibility

(Continued on page 82)

“Here’s what won me that roofing contract”

“It was a fat job—but I couldn’t figure out how to underbid the other fellow. Then I learned about FLEX-A-TILE Slab Shingles, and the saving in labor, freight and nails they claimed. Tried them—and found it was true! A Slab of four FLEX-A-TILE Shin-

gles could actually be laid in the same time as *one* ordinary shingle. They were *self-spacing*. They used only five nails instead of eight. I made a lower bid—and got the contract, thanks to

FLEX-A-TILE

Asphalt Slab Shingles

The name FLEX-A-TILE stands for the best quality Asphalt Roofing produced—and that means the best of *all* roofings for durability, beauty and economy. FLEX-A-TILE Slab Shingles are a better buy for the client; cost less than a wood-shingle roof. They are a better choice for the contractor; save him time and money on the job, and stand as a lasting advertisement of his work.

FLEX-A-TILE Shingles are made to *endure*, of thick wool felt, saturated in twice its weight of the highest-grade asphalt, coated with rubbery gilsonite

and surfaced with crushed slate or granite, under tons of pressure.

Three styles of FLEX-A-TILE Slabs are made, in either rich red or deep green, allowing of many beautiful and varied effects in laying. The colors, being the natural stone colors, only grow richer with age.

Florida Business in "Carey" Products.

The Florida business of the Philip Carey Co., 1020 Wayne Avenue, Lockland, Cincinnati, Ohio, was taken over on Oct. 14 by the Cameron & Barkley Co., well and favorably known throughout the State, having been for some years established at Jacksonville and Tampa. The headquarters of the Cameron & Barkley Co. are at Charleston, S. C., but the Florida operations are conducted from the points named. The Jacksonville branch of the Philip Carey Co. has heretofore done a large business under Manager H. L. Seymour, who will continue with headquarters in Jacksonville. The change has been made because of the superior inducements offered by combining organization and influence with one of the best known institutions of the South. Every effort is to be made to continue and improve the excellent service heretofore offered the users of Carey materials.

The "Standard" Snowguard

Builders and house owners are likely to be interested in a new snow guard which has recently been placed on the market by William Cromley, Lewisburg, Pa., and a view of which is given in Fig. 6. It is known as the Standard Snowguard and is intended for use on either slate or shingle roofs. It is offered as a strong orna-

Fig. 6—The Standard Snow Guard

mental and durable snowguard, simple in its construction and application. It consists of a strap 1 in. wide, 3/16 in. thick and designed to run 8-in. up under the slate or shingle. The outstanding feature is the spring loop on the end of the guard which is peculiar to it. This spring loop absorbs the sliding snow and ice that might break a rigid guard or loosen the nails or screws with which it is fastened to the roof. It will be noticed that the guard is completed with malleable iron castings which fit over the upturned end of the spring and is held in place by a rivet.

New Sheet Metal Plant

Galesburg Sheet Metal Works, Galesburg, Ill., has completed the erection of a new plant, 50 x 150 ft., of brick and concrete construction. Increased capacity has been provided and plenty of light and ventilation assured by the installation of several large skylights, equipped with ventilators, and windows on three sides of the building. The floor plan includes a drafting room and office at the front, with a driveway between, so that the truck can be driven directly into the shop, thus facilitating the loading and unloading of materials. An electric motor has been installed for power, and in the near future the company will add to its mechanical equipment. This concern manufactures sheet metal cornices, metal ceilings, skylights, finials, crest-

Where there's no fuel there can't be fire

Ambler Asbestos Building Lumber Used for Interior Work in Gymnasium, Washington Irving High School, New York City.

For
Fireproof
Ceilings,
Walls,
Stairways,
Wainscoting,
Partitions,
Shafts, and
Isolation of
Electrical
Apparatus.

GREAT fire disasters in schools, theaters, churches or factories dot the history of the past like red horrors. Don't run the risk of any of the buildings you plan or erect being one of the number. Most of those fires originated in the interior of the buildings, starting from some trifling cause—a carelessly dropped match, an “extinguished” cigarette or a worn insulation. Most of those fires could have been prevented or controlled if the interior work had been constructed of

Ambler Asbestos Building Lumber

Nothing to Burn

For Ambler Asbestos Lumber cannot take fire or communicate fire under any conditions. It is made of Portland Cement, reinforced with Asbestos Fibre—two absolutely non-combustible materials. It practically lasts forever without any attention whatever.

Anything that can be made of lumber can be made of Ambler Asbestos Building Lumber. It can be sawed, drilled or screwed. The natural gray color is pleasing and permanent; painting as a preservative is unnecessary, but when desired it can be painted and grained, and takes a good finish.

Let us send you our booklets showing Ambler Asbestos Products in actual service. Samples, too, if you wish. They will solve your fireproof problems—for interior and exterior.

Wood Turning Lathes

The subject of wood turning is one which is full of interest to the man who works in wood and the hand-turning lathe has never lost its fascination nor its

Fig. 7—The Model "A" Lathe

utility. While automatic machines turn out duplicate patterns in great quantities, the hand-turning lathe is still indispensable in the pattern shop, or, for that matter, in any other woodworking shop where individual work is done. For the shop of the carpenter-contractor or builder, a lathe can be used to great advantage to turn out work that will give individuality to the job. Furthermore, during winter months it can be used to

Fig. 8—The Model "B"

advantage in working up odds and ends into novelties such as candle sticks, toys, etc., which can be sold at a profit during the holiday season. In order to meet the demand for an up-to-date speed lathe built on high duty machine tool lines with self-contained motor, that can be operated from a lighting circuit, the J. A. Fay & Egan Company, 221 to 241 Front Street, Cincinnati, Ohio, has brought out the machine illustrated herewith. It is known as the No. 400 series which embraces three

Fig. 9—Model "C" Wood Turning Lathe

different types. What is known as model "A" shown in Fig. 7 has variable speed motor headstock giving fifteen different speed changes by simply revolving an aluminum cylinder set in the leg. This type is available for use only on a direct current of 110 or 230 voltage. For an alternating current, the makers recommend model "B" shown in Fig. 8. This has the motor self-contained in the base and speed control by means of a single

Try This Aloe Level 10 DAYS—FREE

Easy Monthly Payments If You Buy

Prove the superior quality of the Aloe Convertible Level by testing it out for 10 days. Use it on your every day work laying out buildings, locating foundation piers, leveling up foundations, walls and floors, aligning, shafting walls, piers, etc., for getting angles, or levels anywhere and the hundred and one other things for which you would use a level or transit. Then, if you decide to keep it, you may pay for it in easy monthly payments so small that you will scarcely feel them.

Aloe Convertible Level

is more than a mere level. It is a modified transit permitting double the range of work possible with an ordinary architect's level. Its construction such that sights above or below the horizontal can be taken, making it the finest instrument ever offered at anywhere near the price. For taking vertical sights the instrument is provided with a special convertible bracket rigidly and permanently attached to the cross-bar thus eliminating the extra time that other instruments require for changing the telescope in position to take vertical readings. The telescope which is fitted with a permanent axis, rests in the bracket bearings and owing to our special constructed clips the instrument can be used for leveling while in

this position if desired, although the bracket clips are easily and quickly released from the telescope axis when levels only are to be taken. The telescope is then set in its normal position in the wyes and you have overcome the old method of attaching and detaching the convertible bracket.

Your Own Time To Pay—No Interest

Remember, you are under no obligation whatever to keep the Aloe Convertible Level. We do not even ask you to promise to buy. But you owe it to yourself to see and try it. If it isn't all you expect you may return it at our expense. If you do keep it, you will find the small monthly payments easier than paying rent for an instrument—and at the end of a few months you will own it—absolutely. There's no red tape about this offer—we ask no embarrassing questions—everything is confidential—we charge no interest. You have practically your own time to pay.

Mail Coupon for Descriptive Circular

It explains the Aloe Convertible Level in detail and shows how easily the man without the training of the engineer or surveyor may secure the same accurate results as the expert. Send your name on coupon or postal for free copy and full particulars of our original, unique and popular selling plan.

You don't buy saws often—get the best

You use your saws daily, week in and week out. If they are fine tools they are a source of constant satisfaction and pleasure. Likewise they may be a perpetual annoyance. You owe yourself and your skill as a mechanic the best you can get. We think

DISSTON SAWS

are the best made. The majority of saw users think as we do. If you have used them you are of the same opinion. But if you haven't, make it a point to get a Disston next time. Learn for yourself why they enjoy the world's greatest demand. It's all in the quality—workmanship, material, design. Write for our Hand Saw Booklet.

Something For You

in our Pamphlet 29; viz.:

Valuable Tables for finding size of joist, safe load of joist, actual load on hanger, etc., etc.

Some of these Tables are not in print elsewhere.

The Pamphlet and the Mounted Model Hanger will be mailed on request.

SOMETHING FOR US. We ask your special attention to items 5, 6, 7 on page 5 of the Pamphlet and to the matter on pages 23 and 24 relating thereto.

THE W. J. CLARK CO., Salem, Ohio, U. S. A.

handle, located at the front of the machine. In Fig. 9 is shown type "C," which is exactly like type "B" except in place of the built-in motor it has a self-contained countershaft so that it may be driven from any shaft. This series of lathes is made regularly to swing 12 in. over the ways. Large diameters can be handled by means of outside face plate, floor stand and rest. The beds are made at any length from 4 ft. upward. The 4-ft. size takes 24 in. between centers and each additional foot added to the length of the bed adds 12 in. to this distance between centers. The point is made that the totally inclosed construction of these machines eliminates accidents, keeps the operating parts clean, reduces power and in general tends toward entirely satisfactory operation.

A New Sanding Machine

A sanding machine involving many interesting features and which is especially intended for removing varnish from counters, tables, desk tops, and for dressing up new work, is the automatic electric surfacing machine which has recently been placed on the market by Wayvell Chappell & Company, 358 West Madison

Street, Chicago, Ill., and a general view of which is presented in Fig. 10 of the accompanying engravings.

Fig. 10 — Showing the Sanding Machine in Use on a Desk Top

The machine is of such size as to be readily handled and by using coarse sand paper first, the old varnish is readily taken off clean from the wood. The finishing with a finer grade results in a surface that is smooth and attractive. The company is also calling attention to its improved type of automatic ball bearing electric floor surfacer, the improvement in which is the mounting of the sanding roller in such a way that one end extends just beyond the side of the machine, thus securing uniform work throughout the room and close up to the base board.

The point is made that this improvement in the sanding machine does away with the border work which formerly resulted when a narrow edge roller attachment was used. The sanding roller may be quickly changed to the other side of the machine when needed so that the wall all around the room can be easily reached.

TRADE NOTES

The Sydney Tool Company, makers of woodworking machinery at Sydney, Ohio, has found it necessary to increase its manufacturing facilities and has under course of construction a two-story brick addition 60x100 ft. in plan, which will be devoted entirely to the use of an erecting shop for the machine-tool department.

The cover of the November issue of *Graphite*, the house organ of the Joseph Dixon Crucible Co., Jersey City, N. J., contains a reproduction of "Eldorado," the master drawing pencil. Throughout the issue are scattered various interesting references to this pencil. In referring to the company's new building, it is said that over 25 miles of piles have been driven into the ground as part of the foundation for the new Dixon storage and stable building. The structure will be 210 x 199 ft. and three stories high. The piles are of Southern pine, are 1825 in number and average 75 ft. in depth.

One of the most valuable means by which the strength of a roofing material can be estimated is in its condition after being subjected to a severe climatic test in actual service. On Sept. 28 a severe tropical storm swept over the South, the wind reaching a velocity of 120 miles an hour. The house of P. C. Authement, Lockport, La., had just been roofed with J-M transite asbestos shingles, made by the H. W. Johns-Manville Co., 296 Madison Ave., New York City, and it is said that the roof was entirely free from damage, although practically every other roof in the city suffered injury of some sort.

(Continued on page 88)

The Lesson Fire Taught

The world will never be shocked and horrified again by the story of a fatal fire in the Missouri Athletic Association Building, for the beautiful new building shown herewith is an almost perfect example of fire-resisting construction.

Kno-Burn

That Carborundum Niagara Grinder Puts New Life Into Any Edge Tools—

My plane bit for instance was way off—needed grinding. On one corner of my work bench is the ever handy Carborundum Niagara Grinder. A few turns and the bit is sharp—you never saw a wheel that cuts so clean and quick as that Carborundum Wheel. Every Niagara Grinder has one. ¶ Then a couple of rubs on a Carborundum sharpening stone and my plane bit has a keen, smooth edge that will stand up on the job. ¶ That Carborundum Niagara Grinder is a dandy tool. Easy and smooth running—well made—durable—every one of you fellows should have one.

Ask your hardware dealer. Send for the Carborundum catalog.

THE CARBORUNDUM COMPANY, NIAGARA FALLS, N. Y.

Owned and Operated by Nicholson File Company

"Concrete Swimming and Wading Pools and How to Build Them," is the title of a new booklet being sent out by the Portland Cement Association, 111 West Washington Street, Chicago, Ill. It contains much interesting information along lines indicated by its title; also numerous half-tone engravings of outdoor swimming pools, both public and private, together with diagrams of the proper construction of a wading and a swimming pool. We understand that any reader of THE BUILDING AGE can obtain a copy of this instructive little booklet free of charge upon application to the address above.

Universal Floor Scraper Company, 166 Union Street, Worcester, Mass., is directing the attention of carpenters and builders as well as others interested to the Universal floor scraper which is now being handled under a new management. The claim is made that better service is being given together with an important machine carrying the company's patent sharpening device. It is stated that over 3000 Universal floor scrapers are in daily use, and any reader interested can obtain full information regarding the device by writing to the address given above.

That oak as a flooring material is well and favorably regarded is evidenced by the number of houses in which it has been laid both when the house was built and in remodeling, the $\frac{3}{4}$ -in. thick flooring being often laid directly over old floors of other material. The merits of oak flooring are set forth in a circular letter of the Oak Flooring Service Bureau, 1349 Conway Building, Chicago, Ill. On the reverse side of the letter is a reproduction from Sweet's 1916 catalog giving various items of information concerning oak flooring.

Henry Disston & Sons, Inc., Tacony, Philadelphia, have awarded contract to the Austin Company, 53 Transportation Building, Philadelphia, for the erection of a one-story concrete and steel machine shop, 73 x 150 ft., at Unruh Street, east of State Road, at an estimated cost of \$29,000.

The H. W. Johns-Manville Company has just opened a new branch office on the fourth floor of the Ford Building in Great Falls, Mont., this increasing the company's branches to 55 in number. The new branch is in charge of J. H. Roe.

An interesting 24-page booklet devoted to general rules and suggestions for the erection of Star section galvanized iron lightning rods, has been issued by Reyburn, Hunter & Co., Philadelphia, Pa., and Chicago, Ill. Seventeen of the pages are devoted to roof plans which are presented to illustrate the methods employed in connecting the rods and also the groundings. These drawings cover a variety of buildings and include residences, barns, silos and a church.

One of the late publications of the Portland Cement Association, 111 West Washington Street, Chicago, Ill., is entitled "Concrete Linings for Irrigation Canals." Much interesting information along lines suggested by the title is contained, and we understand that any reader of THE BUILDING AGE may obtain a free copy by applying to the above address.

One of the interesting exhibits at the Country Life Permanent Exposition at the Grand Central Terminal, New York City, is a unique eight-room bungalow constructed entirely of North Carolina pine by the North Carolina Pine Association, Norfolk, Va.

Much of the appearance of a house depends on the way it is painted, and in the September issue of *The Carter Times* there are several articles containing valuable information relative thereto. It is undoubtedly true that painting efficiency depends greatly upon the

BLUE

"NOT ONE COMPLAINT TO 2,000,000 FEET SOLD AND USED"

**The *DEPENDABLE* Wall
Board with the *BLUE* Center
will *SATISFY* your customers**

THE color in itself doesn't mean a blessed thing. When we created the color center in wall board five years ago, instead of blue we could have used pea-green or salmon-pink, so far as affecting the quality of the board was concerned. We didn't use color to hide old, re-worked materials or cheap, dirty fibers. Upson Board is, and always has been made only of highest-grade pure wood fibers. Nor did we use cheap, smudgy dyes which may blacken or stain the floors when the sawdust cuttings are tracked round. We originated the idea of a wall board with the distinctive construction of two light-colored faces and colored center simply as a ready means of identification and protection to buyers. There is no physical reason that we know of for making any board with a colored center—no reason. In fact, unless it is to approximate the construction of dependable Upson Processed Board.

It is what the color **STANDS FOR** that counts. The **BLUE** Center means that you are not getting a mere imitation of another board. The **BLUE** Center is the mark of genuine **UPSON PROCESSED BOARD**.

THE BOARD WHOSE MAKERS **ORIGINATED** NEARLY EVERY WORTH-WHILE IMPROVEMENT AND INNOVATION IN WALL BOARD DURING THE PAST FIVE YEARS.

Upson Board is the board that stands squarely on its **RECORD**. Not one complaint to two million feet sold and used!—and used in every form of building construction, including some of the most important building jobs in the country.

It is the wall board that has proved to the carpenter and builder that there is a **DEPENDABLE** wall board—quick and easy to install and giving lasting satisfaction when it is installed.

The **BLUE CENTER** is important because it stands for **YOUR PROTECTION**. We originated it so that you could instantly identify Upson Processed Board and be fully protected against imitations. For this reason, too, we were obliged to go to law and have Upson Processed Board legally established as the one wall board that has a right to the blue center.

DO NOT BE CONFUSED by imitations using centers of other colors. If a board hasn't the **BLUE** center, it isn't genuine Upson Processed Board.

Upson Processed Board is made good to make good. It is honestly made and honestly sold on its own merits, and we are proud to attach our own name to it.

Send for free booklet, samples and full information.

THE UPSON COMPANY

Fiber Board Authorities

20 Upson Point Lockport, N. Y.

UPSON PROCESSED BOARD

LOOK FOR THE FAMOUS BLUE CENTER

mixing, and the proper method of doing this is interestingly told in "The Better Way to Mix Paint." Another worth-while article is "White Lead as a Vehicle Surfacer," and additional information concerning the best method to break up white lead is found later in the issue. Those of our readers who are interested in painters' wages will find a table covering the hourly wage, number of hours constituting a day's work, overtime, etc., in different parts of the United States. The issue is an excellent one and these are only a few of the many things contained of interest and value. A copy may be obtained by readers of **THE BUILDING AGE**, free of charge, upon application to the Carter White Lead Co., Chicago, Ill.

The use of sheet metal on farm buildings is growing because of the fact that the farmer is realizing that it is a wise investment to insure his structures against early deterioration and loss from fire by lightning when the buildings are erected. The application of sheet metal to old frame buildings is also a source of profit to the contractor, and it is economy to buy high-grade materials. In this connection a profusely illustrated catalog of 184 pages issued by the Berger Mfg. Co., Canton, Ohio, is of especial interest, as it shows an extensive line of sheets for roofing and siding, as well as eaves trough, ventilators, shingles, etc. All metal products are guaranteed because of the exceptional facilities offered by the operation of its own steel plant, rolling mills, galvanizing plant, etc., that enable the company not only to control the quality in every progressive stage from ore to finished product, but to effect economy in the cost of production.

Builders who are investigating the merits of asphalt shingles will be interested to learn that Bird & Son, Dept. B., East Walpole, Mass., are distributing miniature samples of their new process built-up Neponset Twin shingle. The sample is sent out between covers upon which are contained various items of information concerning the shingles. There is also a page containing on one side reproductions in colors of shades in which the shingles are furnished and on the other a colored cross sectional view showing the construction.

George Rhines, formerly with Crane Company, Chicago, and later manager of Stanley G. Flagg & Co., has been appointed secretary of the Allith-Prouty Co., Danville, Ill., and F. C. McClimans, for several years in the Chicago office and later with the Payson Mfg. Co., has been appointed sales manager for the Danville concern.

It is interesting to note that "Medusa" white Portland Cement was selected for use in connection with the latest improvements made to Buckingham Palace, the residence of the Kings of England, now occupied by George V., and in the erection of the Queen Victoria Memorial.

The Pyrolin Products Co., Inc., Fort Dodge, Iowa, has issued an interesting 32-page book which describes the features of "Pyrolin" fire-resisting linseed oil paints and products. It contains abundant evidence that a building treated with this paint will successfully resist fire, no matter how fierce the flame may be. Information is also contained in a separate folder on "Pyrolin" shingle stains, which are said to be the only kind containing linseed oil, creosote and fireproofing. They are made in six colors, and about four hundred shingles can be stained with one gallon, or from 150 to 200 sq. ft. per gallon when applied with a brush. The company will send any reader of **THE BUILDING AGE** copies of these interesting publications on application.

Contractors and builders having a preference for solid concrete silos will be interested in the 48-page catalog issued by the Monolithic Silo & Construction Co., Chicago, Ill., and which illustrates and describes "Monso" steel silo molds. With this equipment the concrete is poured into the mold, which, after the contents have thoroughly set, is raised and the process repeated, re-

(Continued on page 92)

Circulars of our Faultless or other styles sent upon request.

ASHLAND PUMP AND HAY TOOL WORKS, Ashland, Ohio

sulting in a single homogeneous structure. The outfit comprises a mold, scaffold hoist and bucket, with a system of cold-drawn mesh reinforcement. In addition to several articles on silos, there are tables of silo capacities and material requirements for silos of various sizes.

The first and only motor truck ever owned in the Bahama Islands is a Federal. It is used on the Island of New Providence to haul pineapples from a plantation to Nassau.

The Monitor line of sheet metal products, made by B. F. Lichty & Sons Co., Waterloo, Iowa, is treated in Catalog B that is being sent to contractors and builders throughout the country. Considerable space is given to a description of cupolas, and mention is made that they are shipped assembled with the exception of the top, which is easily bolted in place, which effects a saving in labor and insures a more substantial job. Details of construction are presented and the subject of proper ventilation of farm structures is handled intelligently. The company also manufactures skylights in nine sizes, which are described and illustrated.

The door problem is always an interesting one, whether it be for the closing of openings in the house, garage or barn, for the method used must necessarily be convenient and economical, and a knowledge of the various door equipments is therefore of value. Several booklets bearing upon this subject are being distributed by the Richards-Wilcox Co., Aurora, Ill., and embrace "R-W House Door Hangers," "Garage Door Hardware," "Doorhangers, Grindstones and Hardware Specialties," together with folders upon similar subjects. Illustrations, both halftone and line cuts, show the fixtures and their construction. The text gives various items of information concerning these products, and the booklets will doubtless prove of reference value to many.

There are several types of chain drives upon the market, each of which is adapted to some particular use, but the average layman is not generally acquainted with the construction and action of these various types. To show just why the particular kind of silent high-speed chain-drive is used upon the American Universal Floor Surfacers, made by the American Floor Surfacing Machine Co., 521 South St. Clair Street, Toledo, Ohio, the company is sending forth a folder by H. H. Wolfe, M. E., illustrating and describing chain types. The folder is entitled "Why a Silent High-Speed Chain Drive Is Used on the American Universal Floor Surfacers."

FOR SALE

One No. 404 Lidgerwood Electric Hoist rated at 7½ H.P. with CO-2504 motor, with single friction drum 12 in. diameter, 15 in. face. Requires floor space of 34" x 43½". This hoist has never been used.

STOVER Mfg. & Engine Co.

Freeport, Illinois

IMPROVED Fireplace Dampers

Stover dampers make the building of fireplaces easy. The labor saved by their use reduces the cost considerably.

Catalog 1590-X describes these and other new style dampers in detail, gives valuable suggestions as to fireplace construction and shows a large assortment of other fireplace fixtures.

If you build fireplaces, send for this catalog. It's free.

We manufacture builders' and household hardware, wind mills, feed mills, gasoline engines.

New York City

Hit the Nail on the Head

with your clients by omitting lath
and plaster from your next job
and using only

CAREY
Ceil-Board
SUPERSEDES PLASTER FOR
WALLS
AND CEILINGS

Your big profit comes from the fact that your least expert labor can apply it quickly and perfectly, making a beautiful and permanent job without any of the delay, inconvenience or dirt of plastering. Plain or natural wood finishes. A pair of hands, a claw hammer and some nails are all the tools required.

Write for samples and handsomely
illustrated booklet.

THE PHILIP CAREY COMPANY
1020 Wayne Ave., Lockland, Cincinnati, O.

Shut Out the Cold with BEAVER BOARD

Possibly you don't appreciate that in addition to its beauty and its ease of application, Beaver Board makes warmer rooms than lath and plaster.

To prove it, place your hand on a Beaver Board wall. Not a suggestion of chill. The plaster wall, on the contrary, is cold and clammy.

Beaver Board offers the same resistance to summer's heat. It resists sound and fire, too.

There are many other things which every builder ought to know about Beaver Board.

Write for booklet and further information.

THE BEAVER BOARD COMPANIES
610 Beaver Road, Buffalo, N. Y.
Branches in principal cities

"You can't expect Beaver Board results unless this trade-mark is on the back of the board you buy."

WATERPROOF PLASTERGON WALL-BOARD

(See how this 10 ft.
panel stands straight
without bending! Send
for actual photo.)

Better Profits

Your profits on a wall-board job depend not alone on the first cost of the board—but its cost to you in handling—and its cost to you in reputation if you make a bad choice. Be safe. Use Plastergon. Our users say, "Plastergon has no equal at any price."

Your Safeguard in Buying (No. 6)

"We have just unloaded the third shipment you have made us of WATERPROOF Plastergon. . . We have received no complaints and we are able to get more money for it than for the old board which was not waterproof."
GEO. G. KENYON LUMBER CO.,
Syracuse, N. Y."

Grimm's Galvanized Corrugated Wire Lathing

"Note the V"
(Pat. Applied for)

requires no furring on account of the V-shaped corrugations which are imbedded at intervals of seven inches. This feature alone is worth considering but that's not all. It **WILL NOT RUST** as it is heavily galvanized with the finest grade of Western Spelter and is much easier to handle and will conform to irregular curves much better than any other form of metal or wood lath.

Walls or ceilings plastered on this lathing **WILL NOT CRACK OR DROP OFF**, owing to its great keying qualities, which we will explain if you will drop us a card asking for our booklet No. 61 and samples.

We also manufacture Greening's Patent Trussed Steel Wire Lathing, "Buffalo" Crimped Wire Concrete Reinforcing, "Buffalo" Wire Cloth of all kinds and Wire and Artistic Metal Work for all purposes. **DROP US A LINE AT ONCE** and ask for Catalog 8-H.

The Only Tapered Asphalt Shingle

Winthrop Tapered Asphalt Shingle

Just ask for a sample shingle. See how tough, how pliable and how durable it is. See how it is made like a wooden shingle—thick at the butt and thin at the top. See how easy to lay it is. See what a beautiful roof it will make—red, green or slate-black. Then you will understand why owners want the Winthrop when they know about it.

Winthrop Tapered Asphalt Shingles will enable you to get most of the roofs in your town. They win out with less argument than anything you ever tried to sell, for they look better than wood shingles and they have all the protection of asphalt.

THE BECKMAN-DAWSON COMPANY
ASPHALT SHINGLES

Stamped Under 900 Tons Pressure!

Colonial Panel No. 4055.

"BERGER'S" Classik STEEL CEILINGS

are no longer made by the old drop hammer method but on a specially designed draw press having a pressure of over 900 tons.

In one operation, this press stamps sheets 24" x 48", bringing out with absolute accuracy and precision every detail of the design on the die exactly as it was modeled in the clay by skilled artists.

This advanced step in manufacture is responsible for the superiority of Berger's "Classik" Steel Ceilings.

*Install them in your buildings.
Write for particulars and Catalog D. B.*

50c a Week!

FOR this insignificant sum—less than most of us spend for tobacco—this ten-volume Cyclo-
pedia of Architecture, Carpentry and Building is yours. Yes, and with every set is included—**free of charge**—a 224 page Plan Book and a year's Consulting Membership in the American Technical Society. The Plan Book contains plans, specifications and details, estimates for 116 different structures, including 426 illustrations. This valuable book measures 9½ by 12¾ inches, and is stoutly and attractively bound. The Consulting Membership gives you the privilege of submitting your perplexing problems to a corps of experts for a whole year free. This Consulting membership regularly sells for \$12, and puts at your disposal a wealth of information and the knowledge of men high in the profession.

Fletcher Cunningham, Shreveport, La., writes: "After receiving the books I decided that with their help I could go into the contracting business for myself. I have just closed a contract on which I expect to clear about \$112.00 for two weeks' work."

Use Them Seven Days FREE

The entire ten-volume Cyclopedic, including the Plan Book, will be sent to you by prepaid express upon receipt of the coupon below. Don't send a single penny—just the coupon! Use the books for seven full days before you decide whether or not you want them. If you keep them, you may pay the special advertising price of \$24.80 in easy monthly installments of \$2.00—50c. a week. The regular price of this massive set is \$50.00. Remember, if you don't want the books they may be returned at our expense and you won't be out a penny.

Everything About Carpentry

In the Cyclopedic's ten splendid volumes is everything about carpentry and building, from the first rough sketch of the architect to the acceptance of the finished structure. They include wood, stone, steel and reinforced concrete construction; estimating and contracting; interior finishing and decorating, and modern house lighting and sanitation. Every line is written in plain, understandable language, every difficult point is made clear. The books are handsomely bound in half red morocco leather, gold stamped, and contain 4,780 pages (7 x 10 inches), and 4,000 illustrations, full-page plates, building plans, diagrams, etc. Every subject is cross-indexed so it can be referred to in an instant.

Send the Coupon

Don't send us a single penny. Just fill in and mail the coupon. Then we will send the books to you by prepaid express for seven days' free trial. Remember, you don't assume a single obligation—we are glad to have you see the books for yourself before you decide whether or not to buy. This offer is open to anyone within the boundaries of the United States and Canada. Send the coupon today—Now!

TWO-FAMILY CRAFTSMAN CEMENT HOUSE No. 151

800
Real Live
Building
Prospects

were
handled
by
The
Craftsman's
Architect-
ural
Department
during the
last twelve
months

CRAFTSMAN advertisers have received these names and beyond doubt have secured substantial benefit therefrom.

Of course, this is simply supplementary to the usual direct inquiry received by the advertiser. It proves that CRAFTSMAN followers place implicit confidence in THE CRAFTSMAN Magazine. Business men know this is the first essential in an advertising medium.

Seeking executives of all industries connected with the construction and furnishing of the up-to-date home will do well to provide a CRAFTSMAN place on the 1917 schedule of advertising.

THE CRAFTSMAN gives a circulation without waste—and the advertising rate is attractive.

Readers of the BUILDING AGE are invited to avail themselves of THE CRAFTSMAN'S battery of plans. Over two hundred different designs of beautiful large and small houses have been created by THE CRAFTSMAN'S Architects. Some of these plans may be had at \$5.00 a set; in no case is the cost more than nominal.

Write the Service Department of THE CRAFTSMAN about the type of house you have in mind; probable expenditure, etc. We will help you plan, build, equip and develop.

The Christmas Number of the Craftsman

enclosed in a

MAGAZINE COVER OF CRAFTSMAN SHEEPSKIN LEATHER, GOLD-LETTERED, will be mailed by parcel post with each new subscription to THE CRAFTSMAN received before January 1. The subscription (including December, 1916) will date from January, 1917, to December, 1917, inclusive.

We suggest this to old subscribers and other loyal friends of

THE CRAFTSMAN AS ONE SOLUTION OF THE CHRISTMAS GIFT PROBLEM and ask, if you are interested in this attractive offer, that you will send your order direct to The Craftsman, 6 East 39th St., New York, at once.

THE CRAFTSMAN PUBLISHING CO., 6 E. 39th STREET, NEW YORK CITY.

Gentlemen: Enclosed please find \$3.00 for which you may send THE CRAFTSMAN for one year—January, 1917, to December, 1917, inclusive to:

Have You Made The Mistake

of thinking that Compo-Board is the name of any composition wall board?

Have you overlooked the fact that the genuine

Trade-mark Reg. No. 94745

is made with a center core of kiln-dried wood slats—is the only wall board so made—and as a result of this unique patented construction possesses a strength, durability, cold, heat and moisture-resisting quality, decorative adaptability and other features that make it far more satisfactory than lath and plaster or other wall boards?

Do you know also that it does not have to be paneled, because it saws with such smooth edges, and is so stiff it can be papered? Thus two of the greatest objections to giving up the traditional lath and plaster are overcome.

If you would be modern in your ideas about building, you owe it to yourself to get acquainted with Compo-Board. Write for free sample and interesting book.

The Compo-Board Company

5778 Lyndale Ave. No., Minneapolis, Minn.

DRAFTING IS THE KEYSTONE

to the bigger job for wide-awake, ambitious carpenters, bricklayers, foremen, superintendents, contractors and all men in the Building Trades.

\$45 Course

FREE

Read the

Wonderful Offer

Here Made to You

Get the knowledge—the training—that will make you the Boss instead of the workman. Drafting is the foundation of all big engineering and building jobs. You can learn drafting in a short time in your own home by the "Chicago Tech." New, Quick, Easy, Home-Study Course. Your spare hours are enough. There is a bigger job (than you now have) waiting for you if you only had the training. Read our great offer, then sign and mail coupon today. Remember, there is only a limited number of these special **FREE COURSES**.

MEN WANTED For Big Jobs at Big Pay

CHARLES W. MOREY
President of the College
and Head of a Large
Chicago Firm of Engineers
and Contractors

On account of the rapidly increasing demand for trained draughtsmen, this college has set aside a limited number of free scholarships and will give the regular \$45 course in **MECHANICAL DRAWING FREE** with any one of the Home-Study Courses named in the coupon below; this is in addition to the complete \$15 Drawing Outfit which is also furnished to students free. Take advantage of this unusually liberal offer today, as it will be withdrawn when the allotted number of Free Scholarships has been awarded. It costs you nothing to get full information. No obligation on you.

Study at Home. Hundreds of men are in daily attendance at this old-established college. In your own home you can do the same work these men are doing, and the same experts that teach them will guide you toward the big-pay job. They will prepare your instruction matter. Your work is examined and approved by them. No books to sell. Live, up-to-date blue prints of work in actual construction. **This Complete \$15 Drawing Outfit and full Instructions in Mechanical Drawing Free**

GARAGE EQUIPPED WITH SIX DOOR OUTFIT, OPENING 18 FEET WIDE
DR. J. W. DREYER, OWNER; JOHN ARMBRUSTER, CONTRACTOR

Designed to meet the demand for a fixture that will allow hinge doors to fold and swing inside of building requiring only minimum space. This fixture is not recommended for doors over 3 feet wide.

No. 435 R-W Sliding-Folding
Garage Door Outfits

Four doors hinged together in pairs are required for each opening, one pair folding to the right and the other to the left. When needed, however, five or six doors can be used, in which case the center doors swing free, making ideal entrance doors. Will stand at any angle depending, however, upon the width of the wall space adjoining the opening. Where wall space is greater than width of doors, same can be made to fold back when open, parallel with the front walls. Blue print showing erection details furnished with each order.

Investigate
Keighley
Metal Ceilings

The Keighley line of metal ceilings is the most up-to-date on the market. You can't afford to bother with anything else but modern ceilings. And by modern we mean construction as well as styles and patterns. Learn all about the Keighley lock joint—write for Catalog L. Write today.

S. Keighley Metal
Ceiling & Mfg. Co.
Pittsburgh,
Pa.

The big Edwards' Metal Shingle family is growing fast. One of our late arrivals is here shown. Look it over. Did you ever see a more handsome, novel design, or more clean cut embossing? We've christened this "Baby" after our own great state.

Edwards "Ohio" Metal Shingle

This stunning pattern is made in one size only, 14 x 20 inches. Manufactured from the best quality Worcester Grade Terne Plate, painted or "Tightcote" galvanized. Every good Edwards Shingle feature—and there's a big bunch of them, including our

famous patent interlocking device—is in the "Ohio," of which we are justly proud. *Let Us Send Samples and Agent's Proposition*—The high quality of the former will please you and the low prices will surprise you. You ought to see the "Ohio" and you ought to see it now. Act!

WRIGHT

It makes no difference whether you specialize on Public Buildings, Office Buildings, large or small Residences, you will find

WRIGHT WIRE LATHING

equally well adapted.

You can use it in walls, ceilings or reinforcing concrete floors. It is fire-proof and rust-proof. It may be attached to any type of wooden framework by tie wire.

Our catalog X describes in detail the various sizes of wire lathing for different types of buildings. Every builder and architect should have a copy to refer to. Send for yours.

**For
Walls
That
Last**

Berger's Expanded Metal Lath

YOUR reputation as a reliable builder depends on the lasting qualities of the buildings you erect. This in turn depends on the material you use.

For instance, a bad impression of your ability is left if the walls crack or stain and need frequent repairing.

Plaster your walls on a secure foundation—Berger's Expanded Metal Lath—and you will prevent unsightly cracks and falling plaster. Berger's Expanded Metal Lath does not absorb moisture, hence cannot swell, warp or stain the plaster. It is fire resisting, sanitary, sound proof, and prevents rats and mice from making holes thru the walls. The small diamond-shaped meshes allow a perfect "key," completely imbedding the lath in the plaster, giving great strength. The large sheets (8 feet long and 18 and 24 inches wide) make application easy and speedy.

Build for durability—use Berger's Expanded Metal Lath for both inside and outside walls.

Walter's and Cooper's Painted Tin Shingles

THE SHINGLES THAT LAST

This is the Roofer's Opportunity

We require an agent in your town; may we have the pleasure of sending you a selling proposition, the acceptance of which will put you in a way to unusual profits?

Why use high priced Galvanized Roofing?

Walter's and Cooper's Painted Tin Shingles will make a roof just as lasting and cost you about one-half as much.

A painted tin shingle to be enduring must have as its base a heavily coated sheet of roofing tin, well covered with a lasting coat of paint. This paint must be flexible and dry, tough and hard. On exposure to the sun it must not flake, chip or scale.

Walter's and Cooper's Interlocking Tin Shingles

are stamped from the best grade of roofing tin, and are individually coated by the dipping process in a bath of paint to the above specifications.

Walter's and Cooper's Painted Tin Shingle roofs put on over thirty years ago are in as good condition today as when first put on the roof. Not only are they long lasting, but they are fire, wind, snow, storm and lightning proof, and are sold under an ironclad guarantee that they are right in every way.

Walls that Yield

THE wonderful elasticity of KELLASTONE (Imperishable Stucco), which may be deflected as much as one and one-half inches in seven feet without cracking, is only one feature of this remarkable material, which will make an everlasting hit with every customer you have. Note, please, these eight points:

- 1st—Its Elasticity.
- 2nd—Rain Proof—without further treatment.
- 3rd—Fireproof and keeps its beauty for all time.
- 4th—Weather Proof—non-conductor—it's warm in winter, cool in summer, immune to expansion or contraction.
- 5th—Bonds perfectly to lath, brick, stone or concrete.
- 6th—Temperature Does Not Affect Its Application—may be applied in zero weather.
- 7th—It's Economical—the most durable of all stuccos, yet cheapest in the long run.
- 8th—It Is the Most Beautiful Stucco Material of all,—practically any finish or color effect may be obtained with it.

KELLASTONE

IMPERISHABLE STUCCO

Upon these points you may stake your reputation as a Builder, Contractor, Architect, or Dealer with any of your customers. Kellastone is the proven stucco. Use it for big jobs or little—old or new. No better recommendation is needed than its use by the U. S. Government, State Institutions, Railroads, large corporations, and for homes in any State in the Union.

KELLASTONE Composition Flooring

will fulfill your flooring needs better than any other flooring. Resists abrasion, deadens noise, and is without seam, or joint, and never cracks or shrinks.

Let Us Send You The Illustrated Kellastone Facts.

The National Kellastone Co.
506 Association Bldg. Chicago, Ill.

Checking Up Progress

Good work requires frequent testing to insure accuracy in progress; and skilled carpenters know by experience that they can do their best work with

Starrett Tools

From use on the simplest operation in squaring up stock to the laying out and measuring of complicated joints and framing jobs, these tools have proved their efficiency. The line includes for carpenters steel tapes, rules, squares, levels, marking gages, builders' combination tools, etc.

Starrett Combination Square. Here is one tool in particular that every carpenter should have—it is really five tools in one—a rule, square, level, bevel, and depth gage. The 12" size sells for \$1.50. These and all other Starrett Tools are for sale at good hardware stores.

Send for free catalog No. 21P describing 2100 styles and sizes of fine tools.

Arkansas Soft Pine

is a non-resinous interior finishing wood of close, tough fiber, fine grain and wide variety of figure. In physical make-up it does not in any respect resemble what is commonly known as "Georgia Pine."

It lends itself readily to stains, which are applied direct without preliminary shellacing. Treated as dark mahogany, this wood rivals the genuine in beauty of texture and finish.

It is the ideal base for white enamel due to the absence of rosin, a quality which insures against discoloration. Moreover, no trouble will be experienced from raised grain.

Because of an abundant supply, Arkansas Soft Pine is readily obtainable and at a price notably less than that of rarer finishing woods of no greater durability or artistic value.

Enameled and stained samples together with
Architects' Manual free on request.
