One Man with the "Union" Combination Saw
can do the work of four men using hand tools, can do it with ease, can do it better. Consider the amount saved—three men’s wages—and compare with the cost of the "Union" saw—in a short time the machine will pay for itself and then the wages saved will go into your pocket.

Every Machine is carefully tested before leaving factory. We guarantee entire satisfaction and they may be returned at our expense if, after ten days’ trial, you prefer your money back.

Suitable for ripping up 3 1/2 inches thick, also for cross cutting, mitering, rebateing, grooving, dadoing, edging up, and with extra attachments, boring, scroll-sawing, edge-moulding, beading, etc.

Ask for Catalogue "A," fully describing our complete line of wood-working machinery.

CEMENT BUILDINGS.

Cement Blocks for Hollow Building and Retaining Walls, Partitions, Etc.

THE CHEAPEST WALL THAT CAN BE BUILT, POSSESSING EQUAL ADVANTAGES.

Preliminary and conventional.

Cement Walls can be built of these blocks at much less expense than by any other pattern, and at one-third the cost of brick walls of equal strength and appearance. Adapted to thicknesses of wall varying from 6 to 30 inches; 10-inch walls and 4 to 6-inch partitions sufficient for three story buildings.

Mr. F. E. Kidder, consulting engineer, and author of "Architects' and Builders' Pocket Book" and "Building Construction and Superintendence," certifies as follows:

"I hereby certify that I tested a 14 inch face hydraulic stone block for compressive strength March 21st, 1903. The full capacity of the press, 80,000 lbs., or 1,000 pounds per square inch of concrete, was applied, and with this pressure the block showed no signs of crushing or cracking. Considering the weight of the block, 34 lbs., this test shows that you could build a wall 1,700 feet high before the weight of the same would crush the under blocks. There is no question but what your 14-inch wall has sufficient strength for three-story construction. For taller buildings the lower stories could be increased to 12-inch or 14-inch. It makes an ideal foundation wall, much cheaper than stone or brick, of equal strength, and makes a dry basement or cellar". (Signed) F. E. Kidder, Consulting Engineer.

Blocks are quick made; after taking from the press the hose is turned on them once a day for ten days when they are ready for the wall, they are easily handled and rapidly laid in the wall and can be faced and colored as desired for about one cent per square foot extra.

SPECIAL ADVANTAGES—Low cost; no possibility of moisture penetrating by capillaries; no need to drive down the blocks going through the wall; adaptability to any design; a hollow wall impervious to heat, cold, moisture, being fireproof, having great strength, both crushing and lateral, the bond being practically indestructible; durability, freedom from cracks, light and attractive in appearance; very little skilled labor required, and can be made wherever there is sand, gravel and water. Plants without power capable of turning out 300 sq. ft. of wall per day, only requiring five men (four unskilled), can be established at a very small outlay. Portable machines furnished so that material can be made where it is to be used. Especially valuable in railroad and factory buildings, cold storage plants, etc. Great opportunity for profitable investment.

Agents Wanted for Exclusive Manufacturing Rights, State, County or Town.

For particulars, address

The Napoleon Pulp Plaster Co.
NAPOLEON, OHIO
MANUFACTURERS OF
ELASTIC PULP PLASTER
MADE FROM WOOD PULP. CONTAINS NO SAND OR LIME
And makes a hard, durable, elastic, light and fire-proof covering for walls at low cost.

PARENT PLANT FOR THE UNITED STATES.
A non-conductor of heat, it neither absorbs moisture nor crumbles with age. Its use is
so simple that any good mechanic can apply it as readily as those that have used it
for years. No dirt, no waste, no trouble. No cold or dampness will affect it; no return. The ideal plaster for up-to-date builders. Without the cold,
wind, non-covered, or to be used at the top of electric wires, proof against damage by water, will put a crack, chip or crumble, makes an air-tight wall. Its elasticity prevents cracking of ordinary spacings of backing. Used in every state and territory. City and Village. Information and terms promptly sent to those who send in an inquiry.

WARNING TO MANUFACTURERS AND DEALERS:
The Napoleon Pulp Plaster Co. of Napoleon, Ohio, owns and controls patents cover-
ing the use of pulp in plaster compounds. Their plaster is made under the
same are covered by the Patent. All manufacturers, dealers and all persons, who make, sell or deal in wall plasters, are WARNED against selling or using plasters infringing on our rights.

THE ENAMEL CAN'T PEEL OFF A B-K BRICK

The brilliant glaze is not made by applying liquid enamel to the brick and then burning it in an oven. Such enamel might peel off. The whole B-K Brick is made of one material. The face is polished by the exclusive process of this company. Hence, there is nothing to peel off. The brick and its glaze are one and are as hard as flint.

ANY COLOR --- ABSOLUTELY WEATHER-PROOF

B-K Enameled Brick are manufactured in colors to fit in the color-scheme of architect, builder or owner-white, buff, red, blue, green, black, or any other color. B-K Brick can't lose their colors by the peeling off of the enamel. The weather-resisting and water-proof qualities of B-K Brick are superior, also for the reason that the enamel can't peel off and water can't get under it. The face of the brick never crazes or crackles, leaving interstices for water to penetrate. The booklet (free) will tell you more.

INDIANAPOLIS BLUE PRINT CO.
It is a mistake to suppose that concrete made with Portland or any other cement, is absolutely a safe material to build every sort of work with, or that as now employed is a perfect fire-proof substance. There have been a number of serious failures recently of concrete construction commencing with the fall of three floors of the Hotel Oswego, which fell last October; a warehouse in Pittsburg, belonging to Kautzmann Brothers; the Wonderland Theater at Detroit; the Bell Telephone Company's building at Philadelphia; the Paddington apartment building, Chicago; the Conservatory apartment, Boston; the Johnson Service Company's building, Milwaukee, and the Lawrence Savings Bank at New Castle, Pa. These are only a few of the failures—the most prominent. We could quote a number of others of more or less magnitude. It is not likely these failures are simply because of the concrete being insufficient. More probably the faults lay with the methods, both of using the material and of the mode of construction. As a fire-proof material concrete may be all right, but the many failures in which this material had been depended upon, throws suspicion on its efficiency. Perhaps the failures are due to bad methods, careless workmanship or inefficient inspection, or all of these combined.

An Irish paper recently reported the discovery in a bog, of a long wooden boat. Some men were digging for turf, and their spades happened to hit something hard. On digging away for some hours they revealed a perfect boat carved from the trunk of an oak tree. On it is some very beautiful carving. It is more than 16 feet in length, and showed absolutely no signs of decay, for the wood was so hard that hatchets and other tools scarcely made an impression upon it. It is probably twenty centuries old, at the very least.

It is astonishing to see men who have been contractors for years, make such unaccountable estimates for work. We had brought to our attention a case in point the other day, when five carpenter contractors tendered on the woodwork of a brick house that was to cost something less than $3,000, in which there was a difference of about $500 in the tenders between the highest and lowest. This seems unbelievable, for the parties wanted to secure the contract, so the high tender was not given in because the tender had too much work. This is not an isolated case; such things are happening every day. The only reason we can assign for this state of affairs is that most builders make up their estimates in a haphazard way.

While there is no royal road to estimating, there is no great difficulty in making up a fairly correct estimate both of quantities and cost of labor. Care and perseverance are the main requisites in the make-up of a reliable estimator.

Who is the benefactor of the race that will break the way for the conversion of the desolate roofs of city dwellings into a thing of beauty and a garden of delight? Subjected for a large part of the year to heat of the tropics our houses are built as though our climate was a perpetual winter. Surely it is within the power of our architects to provide for a secure and delightful retreat upon the house-tops, where, for a portion of the year, we might emulate the glories of the gardens of Babylon.
WEIGHING A BUILDING.

BY B. WYAND.

It is very seldom that an architect in this country is called upon to weigh up an entire building, but in those days of steel and iron work and of huge structures supported entirely upon a few stanchions or columns, with the superincumbent weight imposed upon steel girders, girders and bressummers, it behooves every one concerned to have some acquaintance with the operation known as weighing. Far too many men work by rule-of-thumb alone, knowing from their everyday practice the required sizes for steel or wood girders and bressummers in ordinary positions and on ordinary jobs; but, after all, there is nothing like mathematical precision, and a few simple rules I give will be sufficient to ensure this with a minimum of trouble and but very little working out.

In weighing a building or a portion of a building the points to receive attention are—the weight of the carcass; the weight of the floors and their loads; the weight of roofs and coverings, and wind-pressure. In all cases the weight of any exceptionally heavy timbers or of any ironwork should be carefully added. I purpose first to give the data from which to calculate the weight of an entire building, showing afterwards how these may be applied to determine the weight to be borne by any particular portion.

Foundations. The foundations of a building will not, except in special cases, need to be taken into account; for they should be proportioned to the weight of the building they have to carry, and should rest upon a sound and substantial bottom, their work being simply to spread the weight of the superstructure. The approximate weights of lime- and cement-concrete are 120 pounds and 137 pounds respectively to the cubic foot.

Carcase.—Material in walls and partitions must be measured, bringing the weights of timbers and stonework to foot cube, and the weights of every material, such as common wood rafters, 2% hundredweight; 2-inch deal hoarding, 3 hundredweight; 1%-inch deal hoarding, 3% hundredweight; 1¼-inch deal hoarding, 3½ hundredweight; 1-inch deal hoarding, 4% hundredweight; or any ironwork should be reckoned in, but as the weights of timber may be found in any book on building construction, and the weights of steel and iron obtained from any of the numerous catalogues of castings, I do not purpose hampering this article with them. I therefore proceed to weigh part of a building.

To Weigh Part of a Building.

The first example I give (see Figs. 1 and 2) typifies a case to be met with in everyday practice. The building, a dwelling-house, is to be converted into shop premises, and for that purpose the front wall below the first floor must be removed and a bressummer thrown across. We have, therefore, to determine what weight this bressummer will have to bear. Figure 1 is a cross-section taken through the building parallel with the street; figure 2, a section through the building from front to back.

On looking carefully at these sections we find—

1. That the whole of the brick wall in the gable end will have to be supported upon the bressummer.

2. That the first floor is carried on joists supported entirely by the side or return walls.

3. That one end of the second-floor joists is built into the brick wall to be borne by the bressummer.

4. That the weight of the roof rafters rest upon pole-plates, carried (like the first-floor joists) upon the return walls. The roof is a collar-beam roof, without purlins, and the only portion supported (like the first-floor joists) upon the return walls. The roof is a collar-beam roof, without purlins, and the only portion supported (like the first-floor joists) upon the return walls.

Fig. 1. 111111111 Fig. 2.

Now, to take these four items and calculate the weight of each.

Brickwork.—The gable wall supported by bressummer contains (exclusive of openings) 160 feet square of 14-inch work and 150 feet square of 12-inch work. For our purpose this may be taken as one rod, which is, as everyone knows, 227 feet of reduced or 14-inch work.

Timber framing for slate or tile roof, 5 to 6 hundredweight per square. The weight approximately for iron roof-trusses, in pounds (according to Hurst) equals the square of span in feet, multiplied by .7 for spans between 20 and 40 feet, by .8 for spans between 40 and 50 feet, and by .9 for spans between 50 and 60 feet. The weight in pounds of wood trusses equals square of span in feet.

Wind-pressure.—The pressure of wind upon the roof, together with the weight of snow which could accumulate in the heaviest downfall, must always be calculated in weighing a building; for the walls have to support the strain and stress of these in addition to the actual roof covering itself. The question of calculating the pressure of wind upon walls in very exposed or exceptional situations does not come within the scope of this article.

Wind-pressure will, of course, vary largely with the pitch of the roof, and snow according to both pitch and climate, and no one figure will therefore be suitable to meet all cases.

Per square of 100 feet. For wind, vertically on roof, ¾ pitch, 17 hundredweight; ditto, 1½ pitch, 20 hundredweight; ditto, 5 pitch, 22 hundredweight. Snow, according to climate, from 3 to 5 hundredweight. These are practically Hurst’s figures, only he works them out at per square foot super.

Additional load on roofs for pressure of wind, 56 hundredweight, which should be sufficient, and amply so, in all cases for both wind-pressure and snow.

Sundries.—I have said that any exceptionally heavy timber or ironwork should be reckoned in, but as the weights of timber may be found in any book on building construction, and the weights of steel and iron

and iron obtained from any of the numerous catalogues of castings, I do not purpose hampering this article with them. I therefore proceed to weigh part of a building.

The second floor, it will be seen by reference to

Fig. 1.

Timber framing for slate or tile roof, 5 to 6 hundredweight per square. The weight approximately for iron roof-trusses, in pounds (according to Hurst) equals the square of span in feet, multiplied by .7 for spans between 20 and 40 feet, by .8 for spans between 40 and 50 feet, and by .9 for spans between 50 and 60 feet. The weight in pounds of wood trusses equals square of span in feet.

Wind-pressure.—The pressure of wind upon the roof, together with the weight of snow which could accumulate in the heaviest downfall, must always be calculated in weighing a building; for the walls have to support the strain and stress of these in addition to the actual roof covering itself. The question of calculating the pressure of wind upon walls in very exposed or exceptional situations does not come within the scope of this article.

Wind-pressure will, of course, vary largely with the pitch of the roof, and snow according to both pitch and climate, and no one figure will therefore be suitable to meet all cases.

Per square of 100 feet. For wind, vertically on roof, ¾ pitch, 17 hundredweight; ditto, 1½ pitch, 20 hundredweight; ditto, 5 pitch, 22 hundredweight. Snow, according to climate, from 3 to 5 hundredweight. These are practically Hurst’s figures, only he works them out at per square foot super. Young gives a general all-round figure.

Additional load on roofs for pressure of wind, 56 hundredweight, which should be sufficient, and amply so, in all cases for both wind-pressure and snow.

Sundries.—I have said that any exceptionally heavy timber or ironwork should be reckoned in, but as the weights of timber may be found in any book on building construction, and the weights of steel and iron obtained from any of the numerous catalogues of castings, I do not purpose hampering this article with them. I therefore proceed to weigh part of a building.

Fig. 1.
In one place he found that the line of cutting on a granite core made by a tubular drill form a uniform depth throughout, showing that the cutting point was not worn as the work advanced. The regular taper of the core would also go to prove that the drill was set with jewels on the inside and on the outside alike, thereby facilitating its removal. In some specimens of granite he found that the drill had sunk 1.10 in. at each revolution, the pressure necessary to accomplish this having been at least two tons. The capacity of the tools and the skill of the workmen are illustrated by the clean cut they made through soft and hard material alike, there being no difference in the width of the groove when it passes through soft sandstone and granite as hard as iron. Nothing is known concerning the material of which their tools were made or how the jewels were set. The diamond was very scarce at that time, therefore the only logical conclusion is that they used corundum.

Roof.—The small portion referred to above as bedded upon the wall contains about 21 square feet, or 1.5th of a square. The pitch is 1/4, and framing need not in this case be taken into account.

Summary: Brick work, 1 rod, equals 16 tons; floors (dwelling house) 134 square feet, at 114 hundredweight, equals 8 tons and 73/4 hundredweight; roof (slates), 1.5 square, at 8 hundredweight, equals 1 3-5 hundredweight; roof (wind-pressure and snow), 1.5 square, at 36 hundredweight, equals 7 1-5 hundredweight. Total (disregarding fraction) 24 tons, 16 hundredweight.

We find now that we require a bressummer to carry 25 tons over a clear span of 16 feet, 6 inches, and turning to our tables of safe loads on rolled steel joists we find that a 10-inch by 6-inch is guaranteed to bear a load of 141/2 tons. We select two of these in preference to one of greater depth, as we have a 14-inch wall to support above. Their combined carrying power is 281/4 tons, leaving a good margin of safety.

(To be continued.)

OLD TIME TOOLS.

During a residence of two years, in a tomb at Gizeh Wilhelm M. Flinders Petrie collected evidence showing that the tools used in working 4,000 years ago were made with the jewelled cutting edges, as is the modern custom. He gave his reasons for coming to these conclusions, and proved in a very satisfactory manner that the pyramid builders used solid and tubular drills, straight and circular saws, and many other supposed modern tools in erecting that greatest of buildings. He also showed that their lathe tools were set with jewels, and that they did work with them that would puzzle the modern artisan.

HUNT & EAGER, ARCHITECTS.

MARKING BLUE PRINTS.

It has become the custom to use a soda solution, using it as ink, and the result is a white line not very different from the print. The soda on the surface of the paper collects dirt and the lines fade and lose their original intensity. The right way is to write your figure in ink, then take your ruling pen and put a blot of soda over the spot. This whitens the background and turns the ink jet black, and is done in half the time and twice as nicely as any other way. The white spot is there to stay, and the ink will never fade.—The Drafterman.

WORTH KNOWING.

Drain-pipes and all places that are sour or impure may be cleansed with lime water or carbolic acid.

Oil of lavender will drive away flies.

Grained wood should be washed with cold tea.

If a bedstead creaks at each movement of the sleeper, remove the slats and wrap the end of each in old newspapers. This will prove a complete silencer.
Continuing my sketches on Egyptian ornamentation, I may say that at one period the scarabaeus or beetle was a prominent figure in many ways. When employed in ornamentation it was generally depicted on a ground of the royal color, blue. The worship of this repulsive creature is another of the incomprehensible features of Egyptian religion, an insect with all the qualities of repulsion, insignificant, not even venomous, is raised from its sand hill and ranked with the gods; its image is worn as an amulet; it is sacred to the sun, and an emblem of creation and a new life. This may explain its presence on the mummy cases.

The waving lines in the center ground of all designs, are all symbols of the Nile, the zig-zag at the top is still preserved as Aquarius, the water bearer, in the signs of the Zodiac, and we find its traces in the Norman and early English styles. In the tombs, this decoration of the center wall, broad-winged figures of Isis and Nephthys, Fig. 1, either in a sitting or standing position, and with one wing pointing toward the neither world, the other at the sun.

Upon their head was the globe, and over their forehead the deadly Uraeus, symbol of sovereign power, always found in the diadem of the Pharaohs.

There may be many faults in the Egyptian mode of decoration, grace, it is true, has been sacrificed to sublimity, but there was skill displayed in the arrangement, and taste in the selections; the flatness of their drawing was relieved by the admirably harmonious disposal of their colors; everything was made subordinate to effect, moldings were never permitted to interfere with the continuity of the decoration; the custom prevailed of concentrating the ornament to a central point, the columns at the extremities of a chamber were plainer, and became more elaborate as they neared the center, where the climax of elaboration was achieved; and we can readily fall into Denon's enthusiastic exclamation, "One is fatigued with writing, one is fatigued with reading, one is stunned with the thought of such a conception. It is hardly possible to believe in so much magnificence even after having seen it."

Existing contemporaneously with Egyptian art, that of Assyria partook necessarily of it in some degree. The Egyptian influence is found in many of their buildings, the winged globe is often seen and the Uraeus raises its head in the one place as in the other.

The successors of Cambyses, that Assyrian king who conquered Egypt, called Egyptian artists to aid in the adornment of their chambers, and these artists were compelled to adopt the forms which they had been accustomed to associate only with the decoration of the temples in their native country, to the embellishments of private dwellings in Assyria; and by this adaptation and loss of the surroundings which had given them a symbolic character, they became merely decorative figures, void of distinct meaning.

The decorative art of the Assyrian shows us two distinct periods—an older and a more recent one. The older works had a bluish green ground; the latter a light ground, either whitish or yellowish. In both styles the outlines are marked strongly in black or dark red. In the older the outlines are more regular and less correct in their anatomy. Polychromy was known to them, but it is difficult to decide whether they colored in terra cotta or in fresco, with wax or by some other means, perhaps in oil. The incrustation of clay walls with baked and painted, and even glazed tiles, is difficult to explain. In many instances each one has its own color, and by a proper arrangement, squares, diapers and networks were produced. At Babylon and Nineveh the tiles show clear marks of painting. Diodorus gives us a description of the interior wall of the royal palace at Babylon, and says: "It was decorated with all sorts of colored human and animal forms, baked in clay, much resembling nature. The whole represented a hunt!" The principles of decoration with the Assyrians far surpass mere ornamentation in geometrical patterns. Dramatic life of a higher kind is introduced, showing greater artistic power than the reliefs in stone. The outlines are neither black nor red; the treatment is tasteful, the colors a tender blue, brown, white or yellow, and the ground a lightish green.

The winged bull, Fig. 3, was an incident of Assyrian decoration as characteristic as the winged globe of the Egyptians. It figured upon their walls and guarded the entrance to their palaces. It might be properly classed as a composite animal, with the Sphinx of Egypt or Greece, Fig. 2, or the Chimera of Rome; with the differences, that the Egyptian Sphinx was always represented as a monolithic without wings, the Grecian as a female and winged, the Chimera as a monster neither animal nor human, having no prototype, in whole or in part, among living creatures; while the bull of Assyria, selected to sentinel the country, combined the attributes of the protector in bodily strength, a head of wisdom and winged omnipresence.

A profusion of golden paneling and gilded or silvered surfaces, is found in all the discovered palaces. "I have ascertained," says Texier, "that there is not a corner of the palace (Persepolis) in which there is not the most delicate and careful painting; it was the same at Khersabad, at Nimrod, and also at Ecbatana, the capital of Media, where, according to Polybius, in his description of the palace of the Kings of Persia, the porticoes, the peristyles and the walls were covered with plates of gold and silver, which were pillaged by the soldiers of Alexander." This gilding was laid on a base of enameled bricks, overlapping each other so as to form saw-tooth ornament.

Zobeide, in the account of her wanderings related in the variegated volume, "The Arabian Nights," tells of visiting the palace of the petrified queen, and explains that she "discovered a gate, covered with plates of gold, the two folding doors of which were open, a silk curtain seemed drawn before it, and a lamp was suspended inside of the gate." Authorities much more authentic than this one is credited with being, tell of the elaborate hangings indulged in by the early peoples of the East, and the rich stuffs used by them for this purpose. We refer to the unparalleled elegance of the Oriental portieres of today to sustain the reputation of their ancestors, and no more graceful mode of hanging decoration can be imagined than that shown in the fringed border of Fig. 5. It forms the termination of a frieze, and is suspended upon a bar extending around a room; the material used was stuffs, or probably in rare instances silk, and it is a suggestion not unworthy of imitation. It was not unusual for...
alabaster slabs to be set in the walls, held together by clamps either of iron, copper or wood. Above the alabaster slabs, plastered decorations were used; in some cases painted frescos have been found, or mosaics formed with enameled bricks of various colors. Several of the illustrations given are taken from the ruins at Khoyunjik, in which have been found some of the most beautiful and finished examples of Assyrian art. In its border may be traced the influence of the lotus ornament of Egypt, and possibly a distant resemblance to the later honeysuckle of the Greeks. There is one ornament to which the people attached a superstitious regard, probably the only one, but it is used so generally that it would not be doing justice to the subject to neglect to revert to it, even though it does not properly belong to ornamental decoration. A peculiarly formed bush was known as the "Sacred Bush," Fig. 4, and looked upon with peculiar veneration; it is reasonable to think that it has some affinity with the idea of the "Tree of Life," and probably the early people so regarded it.

Not the least noticeable among their lighter innovations was the imitation of a canopy stretched between the spectator and the sky, and bearing the decoration of the ceiling. Assyrian art has left but little influence upon the art of today, very few of its peculiarities survive, and these are not received with a marked favor. Its mission was rather to be a link between the nomadic and the monumental phases of art. Fig. 6 shows the interior of an Assyrian Temple restored, and is doubtless a pretty truthful representation.

**SUGGESTIONS FOR USING PORTLAND CEMENT.**

Keep the cement perfectly dry until ready to use it in mortar. Use dry, clean, sharp sand, and use the least amount that will fill the voids. Increasing the percentage of sand reduces the strength and slows the setting. Wet up only so much mortar at one time as can be used before setting commences.

Do not permit the finished work to dry out quickly; after it has commenced to harden cover with wet sand or burlaps and keep wet for a fortnight. Concrete ditches, flumes and reservoirs should be washed over with a thin cement, groating fast as built. After the mortar has set a day or two it is well to flood it and keep the water standing stagnant a fortnight.

If the finished work cannot be kept covered as above, keep wetting it by daily sprinkling. Water is the life of Portland cement mortar. When concrete is laid in large bodies it is allowable to imbed irregularly throughout its mass as many large stones as is consistent with their being well bonded together by the mortar. In concrete it is desirable that the aggregates should be graduated in size, then they pack closer and require less cement mortar to fill the voids. The stone should be hard, angular and free from dust.

Do not mix lime with cement, it tends to make the mortar crack. In masonry the stone or brick should be thoroughly wet before laying. In sidewalks, as fast as the concrete is tamped to a surface the top coat should be spread on in order to bond the two layers together.

Ordinary lampblack injures cement mortar, mineral colors do not; sienna, Prince’s metallic, Venetian red, Prussian blue, ground coal or oxide of manganese are good.

**A MODERN “COSY CORNER,” ENGLISH STYLE.**

We have often been asked to publish designs of cosy corners, which would not require much cutting to fit up. The one we show in the illustration is in the latest English style, and can be fitted up at the cost of a few dollars, as everything about it is plain, neat and economical. Any carpenter can make the seats, cabinet, and other work.

**MOTTOES FOR THE FRONTS OF HOUSES.**

The text is true, I trow, in every word.

He builds in vain who builds not in the Lord!

Dies schöne Haus ist Sand und Stein.

Wie werden die im Himmel sein.

Translation.

This fine house of stone you see,

What will those in Heaven be?

Though it a thousand years should stay,

This house at last must pass away.

And ere its shortest life be o'er

We shall have gone long, long before!

 Stranger should this catch your eye,

Do a favor passing by;

Bless this house ere you be gone,

And it shall bless you—passing on.

If thou hast evil in thy heart,

Come not in, but straight depart.

In this house all that is good

Is welcome, be it understood.

Good for both, though—be it known,

Not for the good of one alone.

Good for thee.

**Fig. 2. Egyptian Sphinx.**

**Fig. 6. A Restored Assyrian Temple.**
Likewise for me,
So shall we ever well agree!

This house I've built for me and mine,
May it be of peace a shrine,
And may no enmity or sin,
Ever find its way therein!

Enter if a friend thou be,
And if perchance an enemy,
With God's help then let us see,
If we two cannot agree!

If this house be fine or not,
That was ne'er my serious thought,
But it will have gained its ends,
Should I fill it full of friends.

As many bricks as in this house you see,
May friends receive its hospitality,
And when the counting of the bricks is o'er,
May we begin and reckon them once more.

If a welcome thou would'st win,
Wipe your feet, and then come in.

North, South, East or West
A man's own Home is ever the Best.
God shield this House from grief and fire!
And sin—no more need man desire!

I built this House of stone and wood,
I made it handsome as I could;
If it only pleases there.
Then it need not better be.

The two examples shown at Fig. 93 are English and are good examples for the carver. All of these designs may be employed for different purposes, particularly in cabinet work. They are also suggestive of other designs.
An old Kentish chair, made in the sixteenth century, is shown in Fig. 97. Here we have a fine exhibition of carving and carved turned work. The legs, both front and back, show combined turning and carvings, and square faces where the rails are tenoned in the legs. The main posts on the back also show the same features.

This chair was made of black oak, and is as black and as hard now, as though it was made of ebony.

At Fig. 98, I show a fine example of Austrian carving, recently executed in the city of Vienna. This is an open panel and was used in a desk back as a sort of a screen. It is a fine example, and tastefully designed.

I now draw these papers to a close and hope my efforts to induce young carpenters to learn the art of carving, have not altogether been in vain. (Concluded.)
Strictly speaking, the term "Louis XVI. Style" should only be applied to the productions which originated during the reign of that unfortunate king, but such is not the case; for many articles designed and manufactured in the previous reign were quite Louis XVI, (or

Simplicity of outline, tasteful but sparing use of enrichment, and great refinement of detail. Gilt bronze mounts, Sevres plaques, and inlays of various woods, all served to embellish the cabinets and tables of this period, while even the productions of Wedgewood and fine lacquered panels from Japan were brought into requisition for the same pur-

what is called Louis XVI.) in feeling and character. The change of taste from the extravagances of the Rococo to the refined simplicity of the style under notice really commenced during the reign of Louis XV., which fact renders classification according to reign very misleading. In our illustrations of this style, we have only selected examples which we consider possesses the true characteristics of Louis pose. Quivers, torches, amorous emblems, trophies, musical instruments and swags of flowers, favorite objects of decorative treatment with the designers of this date, and we find them constantly recurring in the panels of cabinets, in the bronze mounts, the Sevres plaques, and in various other places, sometimes with the happiest effect. The frequent introduction of vases, tripods, masks and other
antique emblems are also characteristic of the style, and may be attributed to the discoveries at Pompeii and Herculaneum, which took place about this time. The French artists, however, were not satisfied with simply copying from the antique; they certainly borrowed old symbols, but they imparted to them invariably a French flavor, distinct and unmistakable. This antique feeling degenerated later on into the crudity and baldness of the style known as "Empire." The only redeeming feature in the work of this period is the extreme high finish and accuracy of detail which it invariably possesses, but it is utterly devoid of originality of invention; most of the ornamentation being a facsimile reproduction of Roman antiques.

Among the great French cabinet-makers and architects of the latter part of the eighteenth century, the names of Riesener and Gouthière are most familiar, the former for cabinet work proper, viz., the wood-work; and the latter for the highly chased mounts with which the cabinet-work was generally adorned; but there were also many others of almost equal excellence. The South Kensington Museum contains some fine specimens stamped with the names of C. Richer, Oeben, Pafrat, Carlin, and other makers, whose productions will be admired long after their own names are forgotten. Jeaquemart, in his "Histoire du Mobilier," also mentions the names of Martincourt, the master of Gouthière, Delavre, Jean Louis Peuere, Viussac and Bavrio as having assisted in bringing the metal-work of the Louis XVI. period to the state of perfection to which it ultimately attained.

We have sketched on the accompanying illustrations a few familiar details of the style under notice. Among these the Vase plays a prominent part. We find it constantly introduced, in the inlays, in the bronze mounts, and in carved wood, sometimes containing flowers and very frequently terminating with a flame or ornament in the form of a fir cone. The handles of the Vases generally take the form of a Greek key, and from these are suspended swags of laurel or drapery.

Examples of Vases such as we have described are shown on the illustration, also two characteristic Shields of carved wood in the Louis XVI. style. The truss and bracket on the same illustration have been taken from eighteenth century work, and are strictly in character with the style of Louis the XVI.

As a protection to the tin and a preventive of noise, put good roofing felt or paper under the tin.

Use only the finest solder. It takes less material, less time, holds faster, makes the strongest job, and is the cheapest in the end.

Have the seams well sealed with fine solder and allow no acid in soldering, but use resin only.

Have each sheet well eated to the roof, with not less than four cleats to a sheet 20×20 inches.

Paint all tin underneath and as soon as the roof is on thoroughly apply one good coat of paint. In a month or two afterward give it another good coat which will last for several years.

It is a great mistake and injurious to any metal roof to allow the coating to be scratched off and the tin rusted before painting. You paint wood to preserve it; therefore paint the roof when finished.

Select a first-class roofer, one whom you know will do good work and is responsible.

If possible, prevent walking over a tin roof with shoes with nails in, as they dent and scratch the metal. Do not allow boards filled with nails, plaster or bricks and mortar to be dragged over or thrown on the roof after the tin is laid.

If the above instructions are carefully followed and the best brands of tin are used and put on properly by approved methods, you have a tin roof that will last for fifty years.

INTERIOR OF A CHINESE HOUSE.

The illustration shows a Chinese room with some of the interior furnishings. Everything in a native house is the perfection of neatness; everything is in its proper place, and beautifully clean. We do not know a nation equal to the Chinese for their tidiness. The ornaments of the room are quaint, but very pleasing. The native merchant is sitting down smoking his cigar. The walls are covered with paintings and writings, the latter being extracts from the sayings of Confucius and other wise men of China, and nearly all convey some moral lesson or some economic saying. The better class Chinaman at home is a perfect gentleman, hospitable, generous and extremely agreeable, and generally better informed than we give him credit for.

This illustration simply shows a sort of living and reception room, but the better rooms, such as we would call a parlor, are richly furnished, some of them dazzling with oriental magnificence. Rugs and mats being heavy and velvety, and the ornaments of bronze, porcelain, ivories and carved ebony, are beautiful indeed.

Experiments to test the efficiency of acetylene as an illuminant for lighthouses have been made in the harbor of Genoa, Italy. The apparatus used consisted of four separate generators, and for a period of 100 days of ten hours each the lighthouse was served with the new gas with satisfactory results. It is asserted that while the Tino electric light, which is forty miles distant from Genoa, could never be seen from there, the Genoa acetylene light was quite visible at Tino.
THE HENNEBIQUE SYSTEM OF ARMORED CONCRETE CONSTRUCTION—PART V.

BY LEOPOLD HENNEBIQUE, C. E., FROM 1 SURANCE ENGINEER.

The lower room was completely filled with wood and coal, the upper room partially filled with the same materials, and the roof was loaded with 200 pounds per square foot. At 4:06 the fire was lighted on both piles and lasted until 5:30. The fire played so fiercely against the sides and ceiling that the plastering of the latter was calcined, and the wire glass of the windows and doors melted.

The building was momentarily forced out of shape (expanded) but showed no cracks and only very fine fissures, which in no case let the hot air escape. Again the contact of the hand with the outside of the walls could easily be endured. The deflection of the second floor reached a maximum of 5\(\frac{1}{2}\) inch at 5:40; after this time no further increase could be observed.

At 6:30, when, after continual firing, no change in the state of the building could be detected, the commission agreed to extinguish the fire, which was done by directing a stream of water from a hose against the walls and ceiling and afterward against the coal piles.

When, on the following day, the fire authorities examined the building, it was found that the conflagration had not injured the general structure in any way. There was no permanent set in the floors and the few fissures caused by the expansion were completely closed. A series of pyrometers indicated a temperature of 2,500 degrees F.

The photographs show the great range of work done by Mr. Hennebique, including factories of all kinds, as flour and spinning mills, ice factories and foundries with heavy traveling cranes, the runways being also of concrete steel, smokestacks, storage houses and steel blocks, apartment and office buildings of fifteen stories in height, department stores, theaters, museums, banks and fireproof vaults, domes and churches, markets, railroad stations and small switch houses, free supporting staircases, floors of any practical span (those in the Grand Palace of Fine Arts in Paris having a span of 23 feet and a cantilever of 11 feet), exhibition buildings, coal-fans, water-towers, grain elevators, power and irrigation canals, tunnels, retaining walls, wharves and piers, and (last, but not least) bridges.

Armored concrete bridges are indestructible, requiring no supervision or repairs. If of moderate span, they are cheaper than steel bridges and have always a fine architectural appearance.

The five examples shown in this illustration are excellent specimens of stone carving. They are also good examples for wood carving and may be copied with profit. They also offer suggestions in drawing and design, and, as they are acknowledged to be in the best of taste, a study of them will most assuredly elevate the taste of the young student.

German scientists and financiers are busy with peat fuel owing to the dearth of coal. A company in Oldenburg has taken up an invention which claims to reduce peat to coke suitable for all technical purposes. The amount of carbon contained, its great hardness and freedom from sulphur, make it specially suitable for use in furnaces. It can also be used in machine factories, copper and brass smelting works, and in soldering and welding operations.
METHODS OF MAKING CONCRETE.

E. S. Gould states that first-class concrete, as far as manipulation is concerned, may be made in several different ways, all of which, however, must possess the common attribute of a thorough and intimate intermixture of the ingredients. He says:

Upon the whole I think that as good a way as any is to mix the cement and sand dry (this should always be done), and thoroughly drench the broken stone with water and then mix stones and mortar together without further addition of water until the mass has been well turned over. Then, while continuing the mixing, add water (by sprinkling, not dashing) until the proper fluidity has been secured. This depends upon circumstances. In a very wet foundation pit of small area good results may be obtained by pumping vigorously up to the last minute; then pulling out the pumps and quickly shoveling in the concrete without any further addition of water until the mass has been well turned over. Then, while continuing the mixing, add water (by sprinkling, not dashing) until the proper fluidity has been secured. This depends upon circumstances. In a

the stone is hard and sharp the more of it that can be rammed in the better, provided that the pieces are thoroughly coated with mortar. The reason is that the stone is stronger than the mortar, the only object of the latter being to fill the voids and bind the stones together. Of course, this requires great judgment and a competent and faithful inspector, or the license would be grossly abused when the work is done by contract.

Writers on the subject of concrete making do not dwell sufficiently upon the after treatment of the material. The work is not finished when the concrete is made, mixed and rammed. All exposed surfaces must be kept constantly and thoroughly moist for an indefinite period, the longer the better. The top surface of a concrete foundation must be kept wet till it is covered by the superstructure.

very wet foundation pit of small area good results may be obtained by pumping vigorously up to the last minute; then pulling out the pumps and quickly shoveling in the concrete without any further addition of water until the mass has been well turned over. Then, while continuing the mixing, add water (by sprinkling, not dashing) until the proper fluidity has been secured. This depends upon circumstances. In a

BRICK WALLS FOR DWELLING HOUSES.

It is the common practice to use salmon brick in all inside work of walls for dwelling houses, says J. W. Crary, Jr. Then these walls are "furred" and "lathed," so that the plastering will keep dry. Now, this is a great blunder for a wise builder to make. A 9-inch wall, built of good hard brick, in the proper way, without "furring," is better than a 13-inch wall built in the common way with it. If the brick are hard and strong, and laid well in the best kind of mortar, the inside course can be set on edge, three courses on edge, then a "header" to bind. This leaves a hollow space between the outer and inner part of the wall, which is a complete non-conductor of heat, cold or water from the outside part of the wall. Not only that; the expense and nuisance of "furring" and lathing is avoided, and the plastering is put on the brick, and, while adding strength to the wall, is as dry as if put on "lathes."
answers.

from "architect," buffalo, n.y.: in making answer to the query of g. c. k., elkhart, ind., i may say that there is no american work that i know of, devoted altogether to estimating the cost of material and labor of stone-cutting or stone-work generally. tranwinte gives some prices, so also does haswell. kidder gives very little on the cost of stone-work. ira baker's work on "masonry construction," contains a chapter covering some seven or eight pages on the cost of stone-work generally. this is excellent as far as it goes, but does not cover ground enough. each of the books mentioned above are costly, the price of each being not less than 84. a little book published by the david williams company, new york, entitled "estimating brick and frame houses," and costing one dollar, is a very good work on estimating, and gives some figures on stone-work. there are a number of english works which give prices of material and labor of all kinds on stone-work, but they are not adapted to american figures, or american practice.

from "old-mason," dayton, o.: g. c. k., of elkhart, ind., should get a copy of hodgson's "estimating brick and stone houses." i got one from national builder office, and i wouldn't be without it for a cow.

from wm. t. d., illinois, ill.: if g. f. h., new marion, ind., will write "the fairbank's scale co." of this or any other large city, and tell them just what he wants to know; he will get better and more reliable information from them than he can get through this correspondence.

from "bricklayer," cleveland, o.: replying to "builder," toronto, ont., if he cleans off the mortar from his old bricks and sets them well before using, the chances are he will have a wall as good, if not better, than if he used new bricks altogether, as most of the "softs" or "salmon" bricks will have been destroyed or picked out in the taking or throwing down of the old wall, and the bricks that stand this test will be of a good quality; better than the general run of bricks from the kiln. the difference in laying old bricks will not amount to more than 10 per cent, generally not so much. this, of course, means after the bricks have been cleaned of mortar and stacked up. the extra increase of cost in laying old bricks is chiefly because their being more or less corners broken off, or patches of mortar left here and there that must be removed before laying.

mortar for laying old bricks does not require to be quite as stiff as for new work. the quantity of mortar remixed will be about the same as in new work. with regard to colored mortar, much depends on the state of the old bricks. if they are very clean and of good color, then a good red or black mortar would enhance the general appearance of the wall; but my experience has led me to believe that the better way is to lay the bricks with ordinary mortar, making fine joints which may be headed or cut bevel, then stain, or better, paint the whole work over in some suitable color, after which the joints may be lined off with white or other color to suit the taste. as a rule, a wall built of old bricks is better and stronger than one built of new, providing the work is well done and the brick not too old or weathered.

from "general contractor," springfield, ill.: in answer to "young plasterer," st. paul, minn., i will give him my experience on the subject of cement cornices. i assume that the cornices in question are to be executed in Portland cement, and in that case, whether inside or out, they can be finished quite smooth and sharp, so as not to require any troweling whatever. for an outside cornice, having got the mould ready, cut a sheet iron template to the same design as the one to be reduced, so as to show about 3/4 in. thick. this is nailed into the mould. the running laths being in position and ready, make up a gauging of cement and coarse sand, 2 to 1. when this is mixed and softened, apply a thick coat to the wall and proceed to fill up, etc., well into it; then coat again, and so on, until the gauging is brought out to the template, and rough enough to form a good key for the subsequent coat of fine cement. then take off the template. at this stage it will be well to study the setting properties of the pure cement so as to be able to judge the quantity of preparation of the ground. for some classes of decoration, six or eight coats are given before the enamel is applied, the first coat of which is sometimes thinned, the second coat being the finishing coat. further, while paint for ordinary inside purposes may be mixed as follows: genuine white-lead, 13 lb.; patient driers, 1 lb.; raw linseed oil, 1 pint; turpentine, 1/4 pint. terebinc is not recommended for white paint. paper varnish is very friable, and is not durable. a colorless copal varnish, white enamel varnish, or french oil varnishes are most suitable for varnishing white or delicate colors.

from an "old ship carpenter," brooklyn, n.y.: it pleases me to see that there is one true citizen in south bend, ind., who deprecates "old glory"s guttering over from his roof; its not out of my way to help him make provision for this purpose. a good flagpole should consist of a carefully selected norwegian pine, free from knots and flaws, straight and well grown. it should have a diameter from 3 to 5 inches at the top, tapering from 2 1/2 to 3 inches at the top. the method of fixing must depend largely on circumstances, but the pole may in this case be easily secured to the back of the gable by irons built into the brickwork at two or three points—the top one being as high as its proper fixing into the wall will allow. a footstep may be formed if desired by corbeling out two or three courses. wire stays should be provided to a high pole, and in this case two such stays may be employed to anchor on to the main roof if thought necessary. the top of the pole is secured to the truck by a mortise joint, and the latter (which should be of tough piece of flawless oak, elm or ash) is furnished with small knots and flaws, straight and well grown. it should have a diameter from 3 to 5 inches at the top, tapering from 2 1/2 to 3 inches at the top. the method of fixing must depend largely on circumstances, but the pole may in this case be easily secured to the back of the gable by irons built into the brickwork at two or three points—the top one being as high as its proper fixing into the wall will allow. a footstep may be formed if desired by corbeling out two or three courses. wire stays should be provided to a high pole, and in this case two such stays may be employed to anchor on to the main roof if thought necessary. the top of the pole is secured to the truck by a mortise joint, and the latter (which should be of tough piece of flawless oak, elm or ash) is furnished with small

from r. w., auburn, n.y.: in answer to "w. b.," nashville, tenn., i submit the following for describing a moorish arch: let a, b, fig. 2, be given width of arch, and d, c, the given height. a and b erect perpendiculars, and make angles d, c, h, and d, c, each equal to half the vertical angle.

make d, e equal b, and d, f equal to perpendicular height from g or h to c. connect a, f, b, and divide the lines a, g, h, b, a, f, and e, b each into an equal number of spaces, as five.
From points 1, 2, 3, 4, on lines A, G, and B, H, draw lines to C; and from the point E draw through points 1, 2, 3, 4 in A, F, and F, B, intersecting 1 C, 2 C, etc., and through the intersections draw the curve.

From "Old Hand," Louisville, Ky.: In reply to "Young Painter," Racine, Wis., I send the following for white enameling:

Carefully remove all inequalities from the work with No. 0 sandpaper, then apply two coats of zinc white priming paint, which is made by mixing together 2 lbs of zinc white ground in turpentine, with 10 ozs. pale Japan gold size and a little turpentine to reduce the paint to working consistency. When the work is dry and perfectly flat or smooth, apply a coat of best white finishing enamel. The gold leaf may be fixed with a coaches hair brush, using gold bronze paint. If a better gold finish is required, gold leaf may be used in the manner described below. Allow the enamel about four days to thoroughly harden, then make some egg size by beating up the white of an egg in a glass of cold water; coat the enameled surface with this size, using a clean brush, allow a few minutes for the size to dry, and then dust it over with French chalk, using for the purpose a soft pad. Paint in the lines and other decorative work with gold white of an egg in a glass of cold water; coat the enameled surface with this size, using a clean brush, allow a few minutes for the size to dry, and then dust it over with French chalk, using for the purpose a soft pad. Paint in the lines and other decorative work with gold size, then apply the gold leaf. Allow sufficient time for the gilding to harden, then sponge, which will remove the French chalk and egg size, and leave the gold leaf intact. As the chairs may be handled, give the gold leaf a coat of gelatine size in order to prevent tarnishing.

From "Sanitary Student," Philadelphia, Pa.: In reply to "Contractor," of Scranton, Pa., regarding cesspool, the size of the cesspool will depend upon the size of the cottage for which it is to be provided and the number of occupants the cottage will accommodate and, again, upon the frequency of the periods of emptying. A cesspool should be emptied, at the very least, once in three months. According to a well known sanitarian, twelve gallons per head daily should be taken as an average, then, if the cottage accommodates four persons; this will be forty-eight gallons daily, or in twelve weeks, 4,032 gallons, and taken six and a quarter gallons to the cubic foot, the cesspool will depend upon the size of the cottage for which it is to be provided, they may be known as shown as the right hand of Fig. 3, the joints from B to X being drawn from Z, from X to Y from Z, and from X to J from M. From "Carpenter," South Bend, Ind.: I give my plan for getting slats for a circular louver for the benefit of "Carpenter," of Springfield, Ill.: Set up a board in the center, as you may see in the diagram, Fig. 5, with the exact positions of louvers marked upon it. Then square over to the frame back and front and you will not only get the frame accurately set out for the housing, but also the lengths of the louvers and end bevels, measuring, of course, from a center line corresponding to the center board. After all is marked off, you knock out the center board.

From "Mechanic," Cleveland, O.: "Economy," of Dayton, O., had much better buy new files than try to sharpen his old ones by any chemical process, for such files are worthless, that is, if they have been much worn; the acid merely eats away the gum, or loose particles of iron from between the teeth, making them look better, and nothing more. Old files may be re-cut by hand, and be as good or better than when new; the temper is first drawn, they are then ground smooth, re-cut and tempered. They can be re-cut for less than what new ones would cost.

From "Crimson," Reading, Pa.: J. M., New York City, is referred to April number, 1900, of The National Builder, for a good explanation of "blue prints" development. He will get there pretty near all that is known about making blue "prints" with diagrams of...
the appliances required for making them. The description is by Mr. Fred Riessman, of West Point, N. Y., the inventor of Riessman's Polygon and Rafter scale. I think you can get a copy of the paper at the National Builder office if you haven't got it on your file. The article, I believe, first appeared in Carpentry and Building, and if you cannot get a copy of April number of National Builder, you might, perhaps, get a copy of Carpentry and Building which contains the article and illustrations. For the properties of steel I think J. M. should consult some one of the many works on the chemistry of metals; it would take several pages of The National Builder to give even a brief outline of half the properties of steel.

From "Old Stair-Builder," Philadelphia, Pa.: M. C., of Akron, Ind., should keep all his strings and "horse," or carriage pieces parallel in width. If he does this, he will have no trouble in getting a regular softt under his stairs. In framing the carriage, where there is any overwood it should be adzed off after the timbers are in place. Of course, M. C. does not give much data, so it is impossible to give directions that will just suit his particular case. With regard to the stresses he speaks of, as described in December number of this paper, 1902. I have not the matter in hand, so leave that part to be answered by some correspondent who knows all about it.

NOTE.—In answer to L. O., of Rockdale, Wis., we publish and illustrate a cheap wooden lathe article on another page.—(Ed.)

QUESTIONS.

From "A.A. C.," Bloomington, Ind.: I would like to ask of my fellow readers their opinions regarding the quality of "plane stocks." Which is the best and most lasting wood for the purpose, beech, or apple wood? I see that apple wood is listed in price catalogues higher than beech, though the latter wood is most used. Can the readers of this paper who have tried them, recommend the Gage plane, made by the "Gage Tool Co., Wineland, N. J.?" I have found nothing yet that beats the old fashioned beech plane.

From "W. B.," Newark, N. J.: I am engaged to finish and color a "den" or study for a young lawyer, in which there is already a dado ceiling in the room above. Of course, M. C. does not give much data, so it is impossible to give questions in this paper regarding laying out wooden window frames.

From "J. S.," Superior, Wis.: What is the best way to cover the brick and stone work of a handsome school building and left it in natural colors to the best advantage?

From "V. J. B.," Bagley, Ia.: I am in want of information regarding the quantity of Portland cement required for a given area, which kind I will make use of. Please give me some hints as to the best method of doing the work.

From "Willis," St. Louis, Mo.: Which is the best way to remove old whitewash or limewhiteing from a red brick wall? There are several coats on the wall, and I am anxious to remove them so as to harmonize with the wall above, which has not been whitened.

From "J. S.,” Superior, Wis.: What is the best way to cover steam pipes laid in very damp, moist soil. Cold spring water around them condenses the steam as fast as it flows in.

From "Petersburg," W. Va.: Will some "old painter" who knows, tell me what is the best to do with a nice job of grained doors, that have stood for about eight years, as I want to renovate them and make them look fresh and bright? Any information will be appreciated.

From "J. T.", Nashville, Tenn.: Will some one please advise me as to the best way to make concrete steps and sills? Oxide of iron is to be added to the other ingredients for coloring purposes.

From "Builder," Port Huron, Mich.: Would like to have the opinion of fellow readers whether or not a "Porcelain" bath is preferable to enameled iron one? I wish to make use of quite a number of baths this season, and as there are some doubts as to which is the better bath, would like to have the opinions of experts before I decide which kind I will make use of.

From "Young Carpenter," Eastern, Pa.: I have a country church to finish up with beewax polish instead of varnish, and would like some hints as to the best method of doing the work.

From "Finisher," Atlanta, Ga.: How can I finish up cypress in natural colors to the best advantage?

From "Bricklayer," Scranton, Pa.: I have seen a number of questions in this paper regarding laying out wooden window frames with a long twist-bit, insert the bolt, and screw up. Try the standards on the floor and note whether the sills are in line, any necessary alterations being effected either at the bottom shoulders of the legs or on the under side of the sill. Halve and bolt a 2½-inch by 2-inch piece to the front ends of the sills. Then make and fix the brackets, back board, and tool rack.

The headstock and poptop (Figs. 4 to 7) should be made from beech. Prepare the blocks to the dimensions given, the tenon fitting the bed being either solid or screwed on afterwards. In Figs. 4 and 5 the threads must be cut in a screw-cutting lathe, and taper holes bored for the centers. In Fig. 10 a set-screw is used; this is used to hold the prong chuck (Fig. 11), but in a lathe that is only used for wood turning, the prong chuck (Fig. 14) is screwed in, while the poppet mandrel is coned, as in Fig. 6. For metal turning the movable centers are recommended.

Mark off the block (Fig. 14), cut away the wood each end where the center has been marked, and in a similar tower, I now wish to ask how a center can be made for brickwork in a circular tower with a semi-circular head.
the smaller clearing hole right through, also the hole for the holding-down bolt. Cut the brass tube in halves with a fine hack saw and fix the bottom half with a small screw, filing the head flush if it projects above the curve of the brass. Drill oil holes through the caps and brasses, screw on the end brass rubbing washers, rub some red paint thinly on the mandrel, and revolve it in the bearings. The holes, having been bored from the opposite ends, may not be exactly in line, and the red marks will show any discrepancies, and the wood may be pared away to the brass till an even bearing is obtained. It is important that the wooden caps should butt tightly both at the back and on the bottom when screwed home and at the same time the mandrel should revolve without shake. If the mandrel shakes with the caps tightened up, then they must be filed on the bottom and should the caps jam the mandrel before they butt solid on the block, one or more thin liners cut from tin or even brown paper can be inserted. The diameters of the head mandrel are 1 inch and 3/4 inches. A square is filed on the 3/4 inch part for the pulley and the lock nuts are threaded 3/4 inches. The poppet center is 3/4 inches in diameter with a 3/4-inch thread. Mark out the poppet block, bore the hole for the front brass bush 1 inch deep, then bore the 3/4-inch hole through; make a square recess to receive the 3/4-inch brass or iron nut, and screw on the circular plates (Fig. 15). A sash plate and screw bearing on a small piece of brass or copper clamp the mandrel in position, and hardwood clamping pieces with shallow tongues to slide in the bed with iron washers and wing nuts are used for the rest and poppet. An ordinary square nut will do for headstock, as it is only moved forward when the slow speed is used on the driving pulley.

The bearings (Fig. 16) are of hardwood lined with split brass tube, and with washers screwed to the side of the bearing block which made for casting the hand-rest and tees (Figs. 19 and 23), and a 5-inch or 6-inch face-plate, tapped to fit the thread on the mandrel nose, will be required; it should have six 3/4-inch holes for attaching a large flat wood face-plate. Finally, the crank-shaft is of 1 1/2-inch square iron, the collars (Fig. 24) being welded on, or fixed with a setscrew, as in Fig. 25. The cylindrical part that fits in the bearings, and also the neck of the crank, could be worked at the forge, and afterwards cleaned up with a second-cut and a smooth file.

The great cathedral in the City of Mexico cost, it is said, $8,000,000. Its roofs are shingled with brick enough to pave a town of 10,000 people. Brick are the shingles of Mexico. They are fastened down with mortar and there is as much masonry on the top of every church and house as there is in its sides.
44. There is some advantage in taking in order of complexity a series of beams and applying to them some of the results of these articles on beams.

Fig. 56 shows a projecting beam fixed in a wall at $A$. The small weight of 20 pounds is hung at the outer end; the weight of the beam itself is not taken account of. The bending moment at any point is found by multiplying the distance in feet of the point from the end of the beam by the weight 20 pounds, so that it increases regularly. If a point $c$ is taken so that $c = 300$ on any scale, and a straight line $c$ is drawn, a line drawn from any point at right angles to the beam to meet this inclined line will give the bending moment in feet pounds at that point. The shear is the same at every point and it is equal to 20 pounds. It may help the student to think of any part of the beam measured from the projecting end as a rigid body in equilibrium under two couples—(a) a couple of which one force is 20 pounds and its other force is the shear at the point taken, which is 20 pounds, because the two forces of a couple are equal; (b) the other couple is a compound one made up of all the stresses in the fibres above and below the neutral axis.

Fig. 57 shows the same beam loaded at the end and at an intermediate point. If we consider, first, the 30-pound load, it can be dealt with as in Fig. 56; find a point at 300 and draw a straight line from this point to the end of the beam. Lines at right angles to the beam will by their intersection with this line give the bending moments at the points from which they are drawn; a further distance of 10 times 6 equals 60 will give a point $c$, and if this point is joined to where the line meets the vertical line where the 10 pounds is hung we shall have what we may call a compound line of bending moments. The shear for the first 4 feet, measured from $n$, is 30 pounds; and for the remainder it is 40 pounds, owing to the added 10 pounds.

Fig. 58 shows the same beam with a uniformly-distributed load. This load may include the weight of the beam. The line of shear shows that the shear increases from the outer end towards the wall; it increases as the weight increases. The bending moment at any point is found by multiplying the sum of the weights between the point and the end by half the distance; if this is done for a number of points, and if lines are drawn at right angles to the beam at these points and made equal to the bending moments on some scale, the ends of these lines will be found to lie on a curve which may be drawn by joining the ends of the lines. This curve is known to be a parabola.

Fig. 59 shows the same beam carrying both a distributed load and a load applied at the end. The curve marked "Total Bending" is found by adding the ordinates of the 300-pound load to those found for the distributed load curve superposing. (The lines drawn at right angles to the beam and terminated at the curve are ordinates. The student should know that ordinates are not necessarily at right angles to an axis.)

These diagrams are not to be taken as examples of real beams. The end said to be fixed in a wall is not to be taken as a workman-like example of any such fixing. For any practical work the stability of the wall would be an important matter; the beam alone is here considered. The curves and lines show how the bending moment in all cases increases as we proceed from the outer end towards the wall and how in large built beams it will be safe to proportion the different parts to the duty they have to perform.

45. Diagram of bending moments.—$AB$ (Fig 65) represents a beam resting with free ends at $A$ and $B$; and $p$, $r$ and $q$ are loads resting upon it. Draw the diagram as shown. $T$ is the perpendicular of the triangle $APR$; the triangle $QOR$ is equiangular with $APR$, and $h$ is its corresponding perpendicular, $h$ is the difference of the ordinates $w$ is the weight per foot run. The beam $B$ when loaded in the middle has a bending moment greatest at the walls, and equals $\frac{w^2}{8}$. If we have a suitable scale, any such line as $p$ intercepted between the string polygon and $b$ will by its length give the bending moment at any point such as $t$. To find the scale, produce $a$ and $b$ to intersect at $d$, draw $c$ at right angles to $a$, cutting $a$ at $x$; now if the loads $p$, $q$, and $r$ were all concentrated at $x$ the line $d$ would represent the bending moment. This bending moment is the upward force at $x$; so that if the line $d$ is divided into equal divisions so as to represent the number standing for $n$, then it will serve for a scale to measure any such line as $p$ as bending moment at the place.

(To be continued.)
THE USE AND ABUSE OF SCREWS IN WOOD-WORK.

Archimedes is credited with the invention of the screw, but whether the famous geometrician’s labors extended much further than the eulogization of the scientific principles and the mechanical power of the screw, it is difficult to say. If he made a screw, he certainly meant it to be used, and the workmen were well pleased with the performance, for in the whole range of mechanical appliances in the constructive arts there is not a more useful article than the screw. Archimedes is further reported to have said, “Give me a fulcrum, a position, and I will move the earth;” and I will move the world, and, no doubt, if these conditions could be granted to him, he, as well as his father or any other workman after him, could lift the earth, or aught upon the earth, by combination of the tremendous lifting and driving powers exercised by a series of screws, apart from the lever. Screws are various, and of various sizes, forms, and materials, but the same principle runs through them all, whether they be manufactured for use in metal or woodwork or for expecting a lifting, driving, or pressing power separately. Our object here is not to treat of screw-cutting, but rather screw-driving in woodwork, and to throw out some useful hints to the building constituency, and particularly workmen. The use and abuse of screws is a matter of importance to architects, builders, and their clients, for it is according to the way screws may be applied in several building operations, kindred operations that good or bad workmanship will be evidenced.

Screws are more extensively used than formerly in putting together various kinds of wood framing, and even in cabinet and chair work. They have been brought into service in places where their use was not before tolerated by the workmen, as will be seen in the earlier portion of this paper. Much of this is due to the invention of the gimlet pointed screw. Although their existence is generally concealed in furniture and fancy work, they are often present, nevertheless, and too often they are used as a substitute for dowels, dovetails, and tenons in the manufacture of cheap work. It is an instructive and remarkable fact that building workmen of a century or two back, in many operations in carpentry and joinery, discarded, as far as was possible, the use of nails or screws, depending more on carefully jointed work, put together by means of mortise, tenon, dovetail, hardwood dowel, or oaken pin. Their work might have taken a longer time to execute than that done by our present race of joiners and wood-workers, but it was infinitely more lasting, and kept together so long as the timber or wood continued sound. The nearly universal remedy now for every broken article on the part of the jobbing joiner and cabinetmaker is to repair it with the aid of a nail or screw. Glue is even often dispensed with, or used where it will exercise little sustaining power, and colored putty is not only made to cover the heads of sunken nails and screws on the face of a piece of work, but used also to hide bad joints and workmanship. Some years ago the writer examined an old oak staircase and hand-rail in a college, which work was executed more than two centuries since, and in the construction of which not a nail was used. From time to time, over long years, slight repairs were made, but the workmen during their operations were never able to discover that a nail had been used in the original construction. There were mortises and tenons, grooves and tonguing, with no place for fastening of any kind, yet the writer also examined more than one old roof in which the use of iron spikes, nails, and other iron fastenings was dispensed with, and the joining of the timber was effected without their aid. In the hinging of doors and other framework it is necessary to use screws, but, unfortunately, many workmen, if not watched or cautioned, will not do the screwing properly or in a workmanlike manner. In pine, and other soft woods a bradawl is sufficient to make an opening for the screw, which opening, of course, should be less than the thickness of the head, and short of the length of the screws used. It will be found, however, that most workmen, not content with tapping the screw a fourth of an inch or so to give it a hold before applying the screw-driver, will actually drive the screw into the wood two-thirds of its length with the hammer. This the workmen will do to save themselves trouble. If there be two hinges upon a door, and if each hinge has eight screw-holes—four in each plate—the chances are that the workmen will drive half of the screws nearly home in the door-stile and frame with his hammer rather than take the trouble of driving them good and firm. With good reason, if the door be of hard, vigorous or heavy oak, the weight of it will tend to the hinges loosening, and after a time will follow a train of other ills—the “dragging” and “rubbing” of doors, and their makeshift cure is what is known as “easying” them. If remonstrated with for driving a screw nearly home with the hammer, the workman may probably say (as some workmen continually do): “That’s what I always do, and no one has ever complained of the result.” This is an erroneous and mischievous idea. A screw that is nearly driven its whole length with a hammer cannot make a regular and corresponding thread or spiral in the wood, and therefore its binding and maintaining power in keeping the hinge in its place is all but gone. Workmen should be made to drive every screw home gradually with the screw-driver, and not by the hammer. Some of the applications as well as in soft woods, particularly in hinge work, screws should be properly driven, and the aperture or opening made for the passage of the screws should be much less than the thickness of the screw itself. The screw will bite a sufficient passage for itself. In hard wood, however, it is necessary to make a hole to receive its head into the screw in soft wood, and a gimlet bit is needed for making the suitable opening instead of the bradawl. A difficulty is often experienced by persons who wish to withdraw a screw, by finding that though it will turn round inside the aperture of the screw-driver, yet it will not unscrew out. In this case a well-grounded suspicion may be entertained that the screw in question was driven, or nearly driven, home originally by the hammer, instead of gradually by the screw-driver, and that no regular thread corresponding with the screw exists in the wood. Under such circumstances it becomes necessary often to wrench off the hinge or hinges by force, at the risk of the breaking, and this often happens. When hinges have lain undisturbed for years on old doors or other framings, perhaps for a quarter of a century or double that time, it becomes difficult to extract the screws, although they may have been originally properly driven. This arises from the screws rusting in the wood and sometimes from other causes. Workmen themselves often fail to withdraw screws, and are forced to break the hinge to get at them. If possible, it is best to apply heat to the head of the screw, and wrench it out. They often split, and break too, fancy and delicate woodwork articles in their efforts to take off hinges, locks, mountings, and other finishings, despite that simple appliance’s affixed to joinery or furniture work, which has been in use for more than two centuries since, and in the construction of which not a nail has been used. One of the simplest and readiest methods for loosening a rusted screw is to apply heat to the head of the screw. A small bar of iron, flat at the end, if reddened in the fire and applied for a couple or three minutes to the head of a rusted screw will, as soon as it heats the screw, render its withdrawal as easy by the screw-driver as if it was only a recently inserted screw. As there is a kitchen poker in every house, that instrument, if heated at its extremity, and applied for a few minutes to the head of the screw or screws, will do the required work of loosening, and an ordinary screw-driver will do the rest without causing the least damage, trouble, or vexation of spirit. In all work above the common kind, where it is necessary to use screws, and particularly in hinge work and mountings, fancy fastenings and appliances affixed to joinery or furniture work, we would advise the oiling of screws or the dipping their points in grease before driving them. This will render them more easy to drive and also to withdraw, and it will undoubtedly retard for a longer time the action of rusting.

As matters obtain now in carpentry, joinery, furniture, and other woodworkmanship, with regard to screws, although they cannot be dispensed with, yet it would be advisable in sundry classes of woodwork to minimize their use, and in other cases to do without them entirely. They can seldom be used without their injurious effect on the displacement of mortise and tenon or good dovetail or dowel work. The growing practice of putting together wood with screws bespeaks a decadence of skilled labor, and of nails and screws there are far too many pressed into service in workshops and dwellings. While admitting the usefulness of the screw in various ways, we have here endeavored briefly to show its abuse in wood-work, and at the same time to afford some hints for better methods of procedure in building and kindred workmanship.

A NEW FURNITURE POLISH.

The Oesterreichische Farben und Lack Zeitung gives the following:

2 parts white wax, 2,500 parts; water, distilled, 4,500 parts; potassium carbonate, 25 parts; oil of lavender, 4,000 parts; potassium silicate, 1,500 parts of the water, carrying the potassium carbonate, until the wax is saponified. Add sufficient water to replace that lost by evaporation, and stir till cold and add, little by little, under constant agitation, the oil of turpentine, and continue to stir until a complete emulsion is attained. When this occurs add the remainder (3,900 parts) of the water all at once and stir in. In case the mixture is incomplete, add a little more oil of turpentine. Perfume with lavender oil. To use the cream, smear a little of it on a thin soft rag, and with this go over the furniture, then polish with a woolen cloth or bit of flannel. The cream answers equally well for leather upholstering, imitation leather, leather cloth, marble, etc.
THE PONTIAC.

The comfortable six room house shown in this month's supplement was designed by Architect N. C. Gauntt, and built in southern Illinois for a family of four adults. The basement is laid with a cement floor, the parlor and dining room are finished in oak, and the other rooms in yellow pine. The estimate, based on Omaha prices, is given below.

Finish work $52.00

Plastering, 627 yds. 30c. 201.60

Gas fitting 300.00

Total $2,084.85

For incidentals add 5 per cent 147.44

Total estimate $2,232.33

Carpenter wages in Omaha are 40c per hour, but I presume 35c will come nearer suitin localities. I aim to get estimate high enough for it is better to figure too high than too low.

Legal Decisions.

A building erected by a town for a free public library is not subject to a mechanic's lien. Young vs. Inhabitants of Falmouth, 66 N. E. Rep. (Mass.) 419.

New York Lien Law requiring the notice of lien to contain the name and residence of the lesors,
is not satisfied by giving their firm name and place of business. Kane et al. v. Hufford et al., 81 N. Y. Supp. 85.

A mechanic's lien and framework built on posts firmly imbedded in the soil constitutes an "appurtenance" within the meaning of the statute and is a lien on all improvements and appurtenances to the land. Christy Company v. Greater America Exposition Company et al., 93 N. W. Rep. (Neb.) 592.

Where a building contract, which defendant claimed had never been performed as specified, evidenced that defendant rendered a service under the contract, that service being performed at the time of acceptance of the building as erected, and permitted the building as erected, and permitted the tenant to go into possession, and as to what the tenant thereby rendered valid, as against the defendant, was immaterial. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where plaintiff, who was on the bond of a building contractor, agreed with the latter and the owner to complete the work and to receive compensation for his services, was released from liability for the contractor's delay, he became the assignee of the original contractor, and his assignee was entitled to the amount due on the completion of the work was subject to liens that had been perfected in favor of the original contractor. Smith v. Schiele, et al., 80 N. Y. Supp. 1058.

Where, in a suit to enforce a mechanic's lien, it appears that some of the articles were furnished more than ninety days before the filing of the lien, the lien should nevertheless be sustained as to the articles furnished within the ninety days, in the absence of any fraud and faith on the part of the defendant. Woffley v. Hughes, 71 Pac. Rep. (Ariz.) 951.

One who furnishes under a running account with the common owner of a group of exposition buildings materials for use in the illuminating equipment thereof is entitled to a lien on such buildings, where payment is due as a common purpose, though they are not all situated on contiguous lots and defendant is not able to show what portions were used in a particular building. Lehner v. Horton et al., 93 N. W. Rep. (Neb.) 592.

Under the mechanic's lien law of 1895, providing that no lien shall be created under it, if the time stipulated for payment is beyond one year from the time provided for the completion of the work, lien from a contract stipulating for payment by notes, some of which run for years beyond the time stipulated for the completion of the work. Vanderpool v. Knight, 102 Ill. App. 864.

Where an employe, engaged in painting the outside of a tall building, is directed by his employer to continue the expenditure of money in making repairs to the scaffold, and the work is neither completed nor abandoned, the employer is liable for contractor's delay, he became the assignee of the original contractor, and his assignee was entitled to the amount due on the completion of the work was subject to liens that had been perfected in favor of the original contractor. Smith v. Schiele, et al., 80 N. Y. Supp. 1058.

Where a building contract provided that the owner refused to accept it and pointed out defects to the contractor, which he made no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where a building was completed to the point of having the windows and doors put in, but the tenant would not take possession, and the tenant refused to pay for the cost of construction, the contractor was entitled to a lien for the amount due on the completion of the work. Vandercpl et al., 93 N. W. Rep. (Neb.) 592.

Where a building contract provided that the tenant to go into possession, and as to what the tenant thereby rendered valid, as against the defendant, was immaterial. Mitchell v. Williams, 80 N. Y. Supp. 864.

The right to a mechanic's lien is not lost by the mere execution and delivery by the claimant of an order of debenture, debenture the amount of the claim to a third party, where it is not shown that the debenture has been accepted or it acted thereon. Omaha Oil & Paint Company v. Greater America Exposition Company et al., 93 N. W. Rep. (Neb.) 592.

A mechanic's lien attaches to a leasehold interest and to buildings erected by one tenant and so long as that tenant continues to occupy the premises, even in a leasehold interest that such platform is securely and safely supported for the work required to be done. John S. Metcalf Company v. Nystedt, 102 Ill. App. 71.

Where a servant is ordered to work on a platform built by another, it is the duty of the master to see that the servant is provided with a safe place to work, and the servant, if he believes himself entitled to a lien for all work done while in the employ of the employer, has the right to assume that the scaffold or platform on which he is working is secure and safe. City of Richmond vs. Sitwell et al., 80 N. Y. Supp. 1078.

Where a building contract authorized the owner to change the plans and specifications, did not request the contractor to return to the building works in progress, and the contractor did not make no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where a building contract was not satisfied by giving their firm name and place of business. Kane et al. v. Hufford et al., 81 N. Y. Supp. 85.

A mechanic's lien attaches to a leasehold interest and to buildings erected by one tenant and so long as that tenant continues to occupy the premises, even in a leasehold interest that such platform is securely and safely supported for the work required to be done. John S. Metcalf Company v. Nystedt, 102 Ill. App. 71.

Where a servant is ordered to work on a platform built by another, it is the duty of the master to see that the servant is provided with a safe place to work, and the servant, if he believes himself entitled to a lien for all work done while in the employ of the employer, has the right to assume that the scaffold or platform on which he is working is secure and safe. City of Richmond vs. Sitwell et al., 80 N. Y. Supp. 1078.

Where a building contract provided that the owner refused to accept it and pointed out defects to the contractor, which he made no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where a building contract provided that the owner refused to accept it and pointed out defects to the contractor, which he made no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where a building contract provided that the owner refused to accept it and pointed out defects to the contractor, which he made no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.

Where a building contract provided that the owner refused to accept it and pointed out defects to the contractor, which he made no attempt to remedy, the fact that the work was done under defendant's supervision, and in his progress made no difference. Mitchell v. Williams, 80 N. Y. Supp. 864.
THE NATIONAL BUILDER.

Trade Review.

(Readers writing for any catalogue, circular or leaflet mentioned in this department will confer a favor by making mention of THE NATIONAL BUILDER.)

NEW ARTIFICIAL STONE.

The American Hydraulic Stone Company, 214 Century building, Denver, Colo., are sending out to architects, reading matter on their cement building blocks, which they claim make one of the cheapest walls obtainable, at the same time possessing great strength.

A page cut of the Angelus hotel building, El Paso, Tex., which is built entirely of American hydraulic stone, is shown in the catalogue, the walls in this building above the first floor being nine inches in thickness. Both the material and construction were in the hands of inexperienced Mexican laborers and no attempt was made to face the blocks. The building, however, presents a very handsome appearance.

The company is looking for agents to handle the exclusive manufacturing rights in every county and town in the country, and further information will be sent if desired.

Their advertisement which appears on another page of this issue will interest those who could use material of this kind.

CARPENTER'S APRONS.

In the advertisement of the S. G. Roloson Manufacturing Company, Lima, O., which appears on another page of this issue, carpenters will find something of vital interest to them.

This concern is probably the only one in the United States which makes a specialty of carpenters' aprons. They have a large manufacturing plant, capable of turning out thousands of these aprons every day, and doing the work at a minimum expense, hence giving the carpenter the benefit of the low price and the best material and workmanship.

It is strange that an article of this kind has not been put on the market until recently. Almost any carpenter who uses a nail apron would be willing to give 25 cents to have one delivered to him ready for use.

These aprons are made from the best 10-ounce muslin, enough to properly support all projecting parts, and always remain true and parallel.

Carpenter's Aprons.

IMPROVED SAWING MACHINE.

The Barnes Tool Co., New Haven, Conn., advertisers in this journal, show in the accom-

panying cut their E. F. B. Improved Sawing machine made by them.

During 1892, when the World's Fair was being held at Chicago, the Barnes Tool Co. sold a great number of these machines to the builders and contractors on Fair work. This sawing machine is peculiarly adapted to meet the needs of the larger class of builders who have shops without power, and it is not too heavy to be taken out to a building in course of construction, where it will be found useful nearly every hour of the day.

Special inducements are now being offered to cash buyers of this machine, and the Barnes Tool Co. invites inquiry from all who are looking for a practical machine of this kind.

NEW MANTEL AND GRILLE BOOK.

Charles F. Lorenzen & Co., 272 North Ashland avenue, Chicago, have an 88-page catalogue on the press, which they say will be the finest piece of literature in this line ever gotten out. The leaves will be about the size of The Builder's and it will be about twice the thickness.

The catalogue will be off the press by the 16th of the month and will be sent free to any reader.

Grilles will also be another feature of this catalogue and no expense has been spared in getting up the finest designs obtainable and prices which will surprise every builder on account of the low figures.

A NEW TENONING MACHINE.

This new tenoner is the result of an experience of over forty years in tenoner construction and is intended for the lighter class of work.

It will be fitted with single heads that will cut tenons as long as 4½ inches or, by passing the material through twice, six inches long; and can be fitted with double or single cope as may be desired. And it may be fitted with a cut-off saw in the rear as required in sash, door and blind work, or with a cut-off saw in front, as may be preferred in cabinet and furniture work.

The framing is of pedestal form with base wide enough to properly support all projecting parts, and the ways are bolted firmly to the top framing and always remain true and parallel.

“TRUTH ABOUT HEATING”

THE J. H. McLAIN CO., CANTON, O.
Branches in the Principal Cities.

“EVERYTHING FOR HEATING”
A NEW MATERIAL FOR BUILDING.

On account of the manifold advantages which cement has over all other similar substances, it has found its entrance into nearly all the important cities and states where industry is found, and is becoming more and more popular as time goes on.

Among the present building materials which resist the influences of temperature and fireproof, the new building stones manufactured and constructed by Architect H. Maring of Darien, Conn., deserve particular mention.

Fig. 1 illustrates a library, which will be completed within a short time at Darien, in this new material. The first story consists of the library and one store; in the second story there is a concert hall, which may also be used as a gymnasium and meeting room.

These building stones may be used for certain parts of walls and ceilings, as well as for entire buildings.

On account of its practically arranged insulation, the original weight is greatly diminished, and, at the same time, there is obtained a considerable increase in safety, thus making, as a rule, small dimensions sufficient. It is claimed that the use of these blocks saves space, material, and money. They are also fireproof and possess many other hygienic advantages which have been recognized by medical authorities. This construction is especially adapted to this country and it is, without doubt, the cheapest and most advantageous material.

It is the custom in this country to use wood for building purposes, and chiefly thin boards. In dwellings of this kind it is uncomfortable both in summer and in the winter; in the summer it being too warm and in the winter too cold. By using the new construction, which has been patented in the United States, the opposite effect is obtained, i.e., the dwellings are cool in summer and comfortable and warm in the winter, as the material shows the greatest compactness, and by means of practical insulation keeps distant the outer temperature from the inner.

This construction may be used on walls and ceilings in factories, country houses and city dwellings and at a very low price. Catalogues will be mailed if desired.

ACETYLENE GAS GENERATORS.

In the front part of The National Builder will be found a description of the Sunlight Gas Machine Company's machines, which are now being used in so many residences, business blocks, etc., where perfect light is desired.

A perfect artificial light should have the highest illuminating power, and as nearly as possible resemble sunlight, as to its rays, its effect on colors, eyesight and health. Acetylene does not tire the eye. It neither smells, smokes nor makes dirt of any kind and its use cannot in any way prejudice health. The cost of acetylene lighting compared to gas and electricity is very much lower.

As late as four years ago there were as many as some 400 generators, the use of which was permitted by the National Board of Fire Underwriters—today there are only about sixty-two. While the accidents from acetylene have been small in number as compared with those resulting from coal and oil and from electricity used in lighting, it has shared the fate of all innovations—not being properly understood, it was too often improperly handled, which caused it to be distrusted. The “fire board” of the National Board of Insurance Underwriters, having made an exhaustive study, now have it well in hand and unhesitatingly permit its use under certain well defined conditions.

The Sunlight Gas Machine Company have, in their “Onomo” and “Submarine” engines, two of the finest generators for acetylene gas lighting on the market. These generators will supply gas for any home or business house at about the cost of kerosene oil. They are said to be so simple to operate that there is absolutely no danger in their use and there is no labor attached in the way of keeping clean, etc.

This company will be glad to mail catalogues etc., on acetylene lighting.

Mr. F. Reissmann, West Point, N. Y., whose rafter and polygon gauge is used by so many readers of The National Builder, has issued a new catalogue of improved and up-to-date carpenters’ novelties.

With Mr. Reissmann’s rafter and polygon gauge it is possible to obtain instantly and accurately any one of the 363 cuts used in the construction of buildings and roofs. This instrument or tool is rectangular in shape and made of heavy three-ply veneer, size being 2½ x 17½ inches.

One of his latest and most useful novelties is a sandpaper holder for carpenters, cabinet makers, and, in fact, all mechanics who use sandpaper, emery paper or emery cloth. By using one of these holders, the sandpaper will always be held securely in place by means of wire clamps. The heavy felt, with which the holder is covered and over which the sandpaper is placed, will prevent the surface of the articles from being scratched. It saves sandpaper and labor and costs very little.

Mr. Reissmann’s advertisement appears in this issue.

A NEW SIDE WALL REGISTER.

The question of house warming is of greater or less interest to those who are building. In nearly every house of moderate cost a warm air system is being used and it is becoming a problem to arrange pipes, registers, etc., so as to obtain the best possible results.

The Auer Register Co., of Toledo, Ohio, have recently placed on the market a side wall register, which has all the good points of a floor register and without any of the drawbacks common to the old flat register placed in the floor around which carpets have to be cut and which is constantly being filled with dirt and dust.

The Auer Register Co. have also arranged to use two or more registers attached to one pipe, therefore, saving the cost of extra piping and at the same time giving the best results.

In the accompanying illustrations, Fig. 1 shows a register as it appears in the room; Fig. 2 shows a sectional drawing of two registers attached to one pipe.

The question of registers often perplexes builders and furnace men alike. The housekeeper dreads to sacrifice her floors and carpets by cutting holes for registers and thus place a receptacle for dust and sweepings and the furnace man dreads the results of insufficient capacity when they are placed in the wall.

The Auer Register has an enormous capacity and throws the heat well out into the room. It also affords the comfort of a floor register as a foot warmer. In placing these registers on the market the inventor now offers to the public a tried and improved device, which does away with the unsightly and unsanitary floor grate, obviates the cutting of carpets, allows for the use of large pipes, heating upper and lower rooms at the same time; draws off the foul air from the floor; and which is a foot warmer and deflector, preventing, when not in use, a tightly closed ornamental front.

This system of heating is well worthy of attention from those contemplating placing furnace heat in buildings of any description. The cost is moderate and the manufacturers will be pleased to give further information.

CHICAGO.
A NEW OVERHEAD WINDOW PULLEY.

The accompanying illustration shows a new invention which has just been put on the market by the Grant Pulley and Hardware Company, of 25 Warren street, New York.

This pulley is made with three styles of bearings—i. e., ball bearings, roller bearings and the plates and pulleys are all added at different prices, according to the requirements of the customers. The housing is made in one piece of iron, which will resist any possible load without fracture. The housing connects the sash, so that mortar will not plug the wheels. The sash chain or cord is easily inserted with a mouse, which is furnished with each order.

**Fig. 1.**

The manufacturers claim that with this pulley, even for the heaviest plate glass windows, iron weights may be used instead of lead, thus greatly reducing cost. The pulleys can be cut in the frame with any regular pulley machine, and the advantages of using this pulley are referred to by the makers as follows: They can be used in any double or single frames. They hang readily, the weight of the window being concealed from view when the window is closed, as illustrated in Fig. 2. Only lacquered face pulleys are necessary, as this is the only part of the pulley that shows. These can be easily removed, if required, after the trim is placed.

**Fig. 2.**

They require eight inches less of socket room than the side pulleys, and thus an iron weight may be used in many places instead of lead. This, it is said, will save from 100 to 200 pounds of lead to each sash, with a corresponding reduction in the cost of material. They are made in four sizes, with pulleys 2, 2 1/4, 2 3/4 and 3 inches in diameter, with lacquered, bronzed, Bower-Barff and bronze metal faces. Fig. 2 shows a single frame and section of pulley, which, of course, is concealed from view in its use.

**Fig. 3.**

Fig. 3 illustrates a twin window without weights in the mullion. These pulleys can also be used for a quadrant window frame. Used as in Fig. 3, only 2 1/2 inches of head room is required and even the triplet and quadruplet window frames require but 3 inches head room. Another form of this pulley is made, embodying the same principles, but adapted for metal fireproof windows.

The growing demand for overhead window pulleys has caused the Grant Pulley and Hardware Co. to seek larger quarters; consequently, since May 1st they have been located at 25 Warren street, New York city, one door west of their old location.

Their advertisement appears in these columns and for reference they would refer you to the following buildings in which their pulley has been used: Flat Iron building, New York city, D. S. Burnham & Co.; architects; New York Stock Exchange, New York city, George B. Post, architect; Kuhn Loeb building, New York city, James B. Baker, architect; Mt. Sinai hospital, New York city, A. W. Brunner, architect; Y. M. C. A., New York city, Parish & Schroeder, architects; Blair building, New York city, Carrie & Hastings, architects; Yale dormitories, New Haven, Conn.

The many advantages of this pulley can be ascertained by referring to their catalogue, which may be obtained upon application.

**SMALL MITTER BOX.**

A new invention has just been perfected and placed on the market by S. B. McHenry, 121 Lincoln avenue, which is attracting much attention among members of the carpenter unions in Chicago. It is a miter box so small and compact and easily handled that it will only mean a short time when contractors may ask their men to take up the use of this miter box.

**Fig. 4.**

This miter box can be tied to the apron or belt and will swing with any string without hindrance. This is illustrated in Fig. 4. At this time the Samson Cordage Works do not claim to have any new cord, but they do claim to have the same extra grade, only better than ever. This extra grade is widely known as the "Samson Spot Cord," and is used in every case where the very best is desired. Two other grades are manufactured by the company, the "Phoenix," which meets the demand of the man who considers only first cost in his purchase, and the "Massachusetts," a considerably better grade than the "Phoenix."

It is claimed that if the proper size of cord and pulley is used as specified in their catalogue, the "Samson Spot Cord" will outwear any other device for hanging windows. A catalogue will be mailed on application.
THIS IS ALL WE ASK. THE HANGER WILL DO THE REST.

At least you will read our Catalogue, won’t you? Just send us your name and address and we will send it to you so you can use it the next time you are building a Church, School House, Factory, Storeroom, Lodge Room, Residence or any place where a movable partition can be used. We know there are others, but there is only one that is considered BEST, that is what you want to use when you have such a partition to hang. This hanger will not wear out or get out of order, and is fitted for any sized opening.

SATISFACTION GUARANTEED.

SCHALLER-HOERR CO.
CHICAGO, ILLINOIS.
416-426 BLUE ISLAND AVE.
WHITE SWAN PLASTER.

Until a very recent date, common lime mortar has held supreme control of the Chicago market for plastering walls, except in the finest of fire-proof buildings. There have been several reasons for this: First, Chicago has held supreme control of the Chicago market and kilns. Second, every plasterer has been educated in its use, and last, it is the procrustanator's friend, for what he does not wish to do today, can be finished tomorrow.

The Garden City Sand Company, t88 East Madison street, Chicago, are manufacturing a very superior plaster, using Hoover Michigan plaster and pure white sand and selling same under the “White Swan” brand. This brand of hard wall plaster can be put on the walls, no matter what the weather conditions may be outside—whether warm or cold. Cold weather, just above freezing point, is better than the use of salamanders, as the water of crystallization should be taken up before the wall dries out. “White Swan” makes a wall ten times the hardness and strength of common lime mortar. It dries quickly and never needs repairs. Plasterers find that it works cool and spreads easily.

The accompanying cut is one of the new catalogues which have reached our office, that of the New York Belting & Packing Co., 25 Park Place, New York, is one of the finest.

In order to give an accurate idea of their goods the manufacturers are compelled to show their Interlocking rubber tiling in colors and this new catalogue is a masterpiece in half tone color work. It shows seven full page half tone reproductions of illustrations, among the latter being the home of Mr. J. J. Dvorac, 1249 Douglas Boulevard, Chicago, cut of which is shown with this article. The building was designed by Architect James Babka. The Carden City Sand Company guarantees the quality of the “White Swan” plaster to be as represented and their prices are very low compared to the high standard of material.

They make a point of furnishing blank bidding slips upon application and expert hard wall plaster contractors will be sent to bid on work if desired.

RUBBER TILING.

VINEERED DOORS.

The Grand Rapids Veneered Door Company, Ltd., of Grand Rapids, Mich., are specialists in the manufacture of veneered doors and panel work. Their specialty is the door made with the newest and most modern machinery, is devoted entirely to this line. Their veneering is done with a 200-ton hydraulic press and with the very best glue. The company state that they make the center or core of the work from sound stock and that it is just as carefully made as the exterior or face. Architects and contractors will see the importance of this last point in door work, as it is impossible to make good sound and strong doors with rotten or defective core and tenons. The Grand Rapids Veneered Door Company, Ltd., have their own dry kilns, with a capacity of over 100,000 feet of lumber, thus enabling them to use only thoroughly dried material. A hardwood veneered door, when properly made and finished, is a piece of furniture, and this company being located in “the Furniture City,” they take pride in keeping up the reputation for turning out the highest class of work, both in design and workmanship that can be obtained.

Some twenty-six beautiful designs are shown in their catalogue, which will be sent on application to any architect or builder. An idea of the size of the cuts shown in their catalogue can be had from their advertisement in this journal, opposite the editorials. A special point about their doors is the beautiful cabinet finish used, and for a slight advance in price over the ordinary door an elegant polish can be put on, adding much to the appearance of the room or building. The catalogue will be mailed on application, and an illustration of their doors will be found in their advertisement, opposite editorials in this issue.

GRILLE WORK.

The North Western Grille Design Company, 1454-56 Milwaukee avenue, Chicago, have issued a new catalogue of attractive designs and styles of modern grille work. Special attention is called to many original and new designs.

GRILLE WORK.

The North Western Grille Design Company, 1454-56 Milwaukee avenue, Chicago, have issued a new catalogue of attractive designs and styles of modern grille work. Special attention is called to many original and new designs.

The company is prepared to furnish special designs or make estimates on architects' plans and specifications for high grade work in this line. Christenson Bros., the proprietors of the North Western Grille Works, are both experienced and practical men in this line and have a high standing as reputable business men. One reason for their marked success in the grille manufacturing business has been the fact that they give the small order the same careful attention that they do the large one. They use only carefully selected and thoroughly dried kiln-dried woods and every detail in making is carefully attended to.

About seventy designs in grille work are shown in this last catalogue, No. 11. That Christenson Brothers believe in having neat designs is evidenced by the attractive cover on this catalogue.

The accompanying cut is one of the No. 149 and gives a good idea of the style and general make up of their work.

MONON ROUTE.

The remedial properties of the various springs at these famous resorts are world-renowned for chronic ailments of Stomach, Liver, Kidneys and Bowels. You drink the water — nature does the rest.

Excursion Rates and Excellent Train Service from all parts of the Country. Hotel Rates range from $8.00 to $25.00 per week including free use of waters. Accommodations from the plain boarding house up to the finest apartments and service to be obtained in the best metropolitan hotels. Booklet telling all about the waters and giving list of the hotels and boarding houses with their rates most free.

Address Frank J. Reed, Gen. Pass. Agt., CHICAGO.

Locations for Industries. Manufacturing is rapidly developing along the lines of the Chicago, Milwaukee & St. Paul Railway. Industries on a large scale extend to the Mississippi River with indications of reaching the Missouri, Machinery and all the higher classes of manufactured goods are now being exported from this business territory to all parts of the world.

The Chicago, Milwaukee & St. Paul Railway Company’s 6,000 miles of railway, exclusive of second track, connecting track or sidings, traverses eight states, namely:

NORTH DAKOTA, NORTHERN SIOUX, SOUTH DAKOTA, IOWA, WISCONSIN, MISSOURI, ILLINOIS, MINNESOTA.

Express Passenger Trains, Fast Freight Trains Throughout, which comprise a territory full of natural resources and advantages. This railway is geographically well located in relation to the great markets and distributing centers. Beyond its lines is a vast and rapidly developing territory extending to the Pacific Coast.

The Company gives unremitting attention to the development of local traffic along its lines and, with this in view, seeks to increase the number of manufacturing plants on its system, either through their creation by local enterprise or the influx of manufacturers from the east. It has all its territory disturbed in relation to resources, adaptability and advantages for manufacturing.

Specific information furnished manufacturers in regard to suitable locations. Address, LUIS JACKSON, Industrial Commissioner, 600 Old Colony Building, Chicago, Ill.

BOOKS OF REFERENCE
For the Contractor, Architect and Apprentices
Revised up to date
S. W. B. 104 West Fourth Street

PORTER, TAYLOR & CO., 385 Dearborn St., Chicago.

Carpenters' and Joiners' Pocket Companion.
Rules and data and directions for laying out work, and for calculating and estimating. Compiled by Thomas Moton and Joiner Cloth............. 50¢

This is a compact and handy book containing the most useful rules and formulas, practically tested by many years' experience in the lumber factory and building; also a Treatise On the Framing Square. It is by a thoroughly practical builder and contains enough that is not easily found anywhere else to make it worth more than its price to every intelligent carpenter.

Drawing Instruments.
Being a Treatise on Drafting Instruments, with Rules for Their Use and Directions regarding the Use of Scales, Sectors and Protractors. Together with membranes for drawing on parchment, paper, leather, etc. Also a price list of all materials required by draftsmen. Illustrated with numerous accurate illustrations. By Fred T. WHAT IS IT?

The Schubert Mosaic.

The most desirable, the newest and the best
material for floors and wainscoting ever produced.
It is fireproof, waterproof and perfectly sanitary,
in every respect. Made in any color, put down over
old floors, over lath, plaster or brick, easily applied,
easily repaired. No lost time, as it dries quickly.

We have the right to manufacture for the
United States and Canada. Our company char­
tered under the United States Government. We
wish to start a company to manufacture Mosaic in
every state in the Union, and to sell you the right
for one or more states. We make you the proposi-
tion to sell you the state right to manufacture our
Mosaic. We will start you with a complete plant
with material to manufacture enough completed
stock to pay you back your entire investment.
Several plants are already in operation and floors
are being laid in their locality.

There is nothing to compare with it for floors
in bath-rooms, kitchens, halls, restaurants, in fact,
we can guarantee to fill the bill anywhere a first-
class up-to-date floor is needed.

Write us or call at office.

SUBSTITUTE FOR MARBLE

Architects and owners are requested to investigate the advantages of Marbleithic for floors and wainscot. It is a manufactured product and can be made in colors, shades or variegated. The manufacturers are contractors in all classes and grades of tile work. Contracts taken in any part of the United States.

THE MARBLEITHIC CO., DAYTON, OHIO

Framing Made Easy

By using Nicholls’ Square.

Nicholls Manufacturing Co., wish to call the attention of Carpenters to a new framing square they are placing on the market, more especially to the improvement over other squares, the board measures having been replaced by simple rules for framing; by looking under the figure the roof rafter is to the foot. You have the lengths and figures giving the cuts for all the rafter, also for corners. The square is made in Nos. 1, 9, 8 and 24. It is finished in Nickel, Oxidized Coppered and Polished Steel. The only square made by union labor.

For particulars write NICHOLLS MANUFACTURING CO.

Ottumwa, Iowa.

TOPP’S FRAMING TOOL.

A PERFECT TOOL and the only Tool for the purpose ever invented.

Saves from 6 to 14 hours in laying out a single roof. Saves time for the skilled mechanic, and enables the ordinary workman to frame the most difficult roof with absolute certainty.

IT DOES ALL THIS....

It is accurate, thus preventing all mistakes.

It gives angles for any pitch.

It gives lengths for any rafters.

It gives cuts for principals, joists, hips, valleys and cripples.

Saves time for the skilled mechanic, and enables the ordinary workman to frame roofs with absolute certainty.
